ON CENTRIC HYPERTROPHY OF THE PROSTATE.

By W. H. VAN BUREN, M.D.,

PROFESSOR OF ANATOMY IN THE UNIVERSITY OF NEW YORK.

There is a form of prostatic disease characterized by change of shape and increase of size, mainly involving the urethral and vesical surfaces of the organ, but unattended by peripheral enlargement recognizable by the finger introduced into the rectum. It is one of the varieties of hypertrophy of the prostate, and depends upon the same structural lesions which belong to that disease; but in the absence of the usual physical changes in the size and shape of the gland, as felt from the rectum, it is, in my experience, very liable to be overlooked. As it is more likely to produce all the usual obstructive symptoms at the neck of the bladder than the more ordinary forms of prostatic enlargement, and is, moreover, not very infrequent in occurrence, it seems to me to deserve more attention than it has received from surgical writers.

The following quotation comprises all that is contained in Mr. Henry Thompson's excellent monograph on the "Enlarged Prostate," descriptive of this phase of the disease. Speaking of enlargement, he says:—"The tendency is, in some instances, strongly manifested in a direction towards the centre of the organ, or the neck of the bladder. In others, it appears to affect an opposite direction; to become developed very largely at its periphery. In the former, which for brevity's sake may be denominated *centric* hypertrophy, the outflow of urine may be very materially obstructed before the prostate has increased much in weight and size. In the latter, which may be described as *eccentric* or peripheral, a very large development may take place, and an enormous prostate may be encountered in the rectum, and yet little obstruction to the course of the urine will be manifested. This, it is almost unnecessary to remark, is a form far more favorable to the patient than the other."—(p. 28.) Hodgson, Adams, and Civiale are silent in relation to this form of disease.

I may remark here that in both of the cases I am about to relate, I could make out *no enlargement whatever of the prostate, as felt from the rectum*, and I have taken great pains to judge accurately as to this point.

By what evidence, then, in a case of difficult micturition, is the existence of "centric hypertrophy of the prostate" to be established?

1st. By the absence of ordinary stricture in the spongy and membranous divisions of the urethra, as proved by the passage of a full-sized sound, and by the antecedent history of the patient.

2d. By the presence of resistance and pain on carrying the sound through the prostatic portion of the urethra.

3d. By the age of the patient; if he is fifty or over, the chances are in favor of prostatic enlargement.

4th. By the absence of the usual sense of relief after passing water; the frequent recurrence of the desire; the small size and diminished force of the stream (after ordinary stricture has been excluded); and by a peculiar sense of obstruction to the free escape of the urine, of which most patients are conscious.

5th. When cystitis is present, in any degree, these last signs (under 4th head) lose their significance, and the patient must be examined for stone in the bladder. In doing this it must be borne in mind that calculus and hypertrophy of the prostate frequently coëxist, and that the *bas-fond* of the bladder is usually enlarged in the latter case, so that a sound with a short curve must be employed, the extremity of which may be swept over the floor of the bladder behind the prostate. It is generally necessary to repeat this operation (of course with extreme care and gentleness) several times.

6th. In the next place the absence of *atony* of the bladder must be ascertained. To do this, a catheter of ordinary size should be passed *whilst the patient is lying down*, and after he has retained his urine as long as he conveniently can. If the urine flows continuously, without any pressure being made over the hypogastrium, there is no atony.

If you ask a patient with atony of the bladder to pass his water *in the upright position*, the weight of the small intestines pressing upon the bladder from above, with the assistance of the abdominal muscles, will produce a stream resembling very much in size and feebleness that of prostatic enlargement.

7th. The inability of the bladder to empty itself entirely—in other words, the presence of residual urine in the bladder—is a symptom common to atony and prostatic obstruction; and, inasmuch as temporary atony from over-distension is not unfrequently present in enlarged prostate, it is obviously a point of no little difficulty in the diagnosis to exclude the former affection. Examination of the urine, no matter how carefully conducted, unfortunately throws no light upon the question, for residual urine, whether so rendered by obstruction or paralysis, is always turbid and ammoniacal, and liable to contain blood, pus, and phosphatic deposits.

The presence of residual urine in the bladder is ascertained by introducing a catheter immediately after the patient has urinated; and, when present, the diagnosis lies between atony and obstruction.

8th. Finally, we must not lose sight of the fact that cancer involving the neck of the bladder is capable of simulating hypertrophy of the prostrate. I saw an old gentleman of 65 with Dr. McCready, in October, 1862, in whose case this question arose; he had a large tumor in the region of the prostate, which felt not unlike an enlargement of that organ. In another case of epithelial cancer of the bladder, occurring in a gentleman of 55, whom I saw in 1859, I find the following note:—"He passes water more frequently than natural, say ten or twelve times a day, with slight tenesmus. There is always some delay before the stream commences, and its size and force are both sensibly diminished." His prostate was perfectly normal.

I should say that cancer was to be distinguished from centric hypertrophy of the prostate by the greater amount and severity of the hæmorrhage, and pain in the former; the existence of cancerous cachexia; and, above all, by the presence in the urine of the microscopic elements of cancer. When any suspicion of cancer exists, the use of instruments should be avoided if possible.

It is sufficiently obvious that the diagnosis of centric hypertrophy of the prostate requires care and tact, and a practised hand in the use of sound and catheter; but it will well repay the patience required to arrive at a correct judgment. The early recognition of this condition, before the bladder has sustained serious injury, places it in the surgeon's power, by judicious treatment, to save his patient an infinite amount of suffering, and generally to prolong his life.

Inflammation of the bladder from the constant presence of decomposed and irritating residual urine; the danger of calculous deposit from the ammoniaco-phosphatic salts which it always contains in excess; sacculation of the bladder; distension of the ureters; and lastly, but no less certainly, invasion of the pelvis and secret-

ing structures of the kidneys—all follow in inevitable sequence from the obstruction to the outflow of the urine; and nothing short of the intelligent application of the surgeon's art can arrest the progress of this melancholy procession of symptoms towards a fatal termination.

Case 1.—A. R., 64, a healthy, robust married man, farmer by occupation, was sent to me from the country by an old pupil in the autumn of 1865, with a history of difficulty in passing water, constant desire, pain in back and at root of penis, gradually increasing for nearly a year, and one attack of retention, which was relieved by the catheter after much suffering and delay, and no little difficulty in the introduction of the instrument. There was suspicion of stone, of disease of prostate, and of inflammation of bladder; but only the latter had been clearly made out. I asked the patient to make water in a glass vessel; there was a delay of several minutes before it came, and then the stream lacked force and volume, and was ejected towards the last by spirts and with pain. Placing him on his back, I introduced a full-sized conical catheter with a bulbous extremity, and his bladder expelled, without assistance, nearly as much as he had just passed. The instrument passed readily enough, but resistance and pain were experienced just as its shoulder entered the bladder. The finger in the rectum detected no enlargement of the prostate; perhaps it was a little harder than natural, but otherwise normal to the touch. The urine voided was turbid, high-colored, and smelled strong. It colored red litmus-paper blue; and when dried in the sun, the paper became red again, indicating the volatile alkali. Before withdrawing the catheter, I washed out his bladder two or three times by injecting about ℥ iij. of blood-warm water each time, and allowing it to run off, and advised for the present, diluents, abstinence from stimulants, and rest.

The urine deposited a rather copious sediment, which, under the microscope, I found to consist of pus, some blood-corpuscles, and amorphous triple phosphate, with phosphate of lime.

Forty-eight hours afterwards the patient reported that he had retained his urine nearly three hours and a half after the washing out of his bladder—a longer interval than he had experienced for six months—but that the old frequency of desire had gradually returned. I examined his bladder carefully for stone, and finding none, injected again with warm water.

I felt satisfied that the case was one of "centric hypertrophy of the prostate," with moderate cystitis and inability to empty the bladder thoroughly, and decided to teach the patient to introduce the catheter for himself, and to inject his own bladder—once in the twenty-four hours. He proved to be docile and handy, and at the end of three weeks was able to return home very much improved, and feeling confident that he had found the remedy for his troublesome disease. His urine, when he left, was acid and nearly clear; he held it, on the average, nearly four hours, getting up but once in the night instead of three or four times; and was entirely rid of the dread of his water "stopping off" again, which had been his constant fear, feeling that he possessed the ability to relieve himself in case this should occur.

I heard not long ago that this patient remained satisfied with his condition, and without any increase of his disease.

Case 2.—H. M. M., 51, merchant, delicate, but always healthy; married; father died with calculous disease. Came under my care in December, 1863, complaining of failing health, pain in the back, which has existed more than a year; too frequent desire to pass water during the same period, increasing gradually, and latterly occurring about ten times a day. On asking the patient to make water in my presence, I find that he suffers a certain amount of pain in the act, located at the root of the penis and neck of bladder, and that the urine comes slowly, with a thin stream, and partly by a rapid succession of drops. After urinating, his sense of relief is not perfect; and, on questioning him closely, I find that he has rarely, of late, been entirely free from a feeling of uneasiness about the bladder, suggestive of a desire to pass water. He is regular and temperate, almost abstemious in his habits, and has never had gonorrhœa. An ℥ viij. phial full of his urine, which is turbid, deposits a stratum half an inch deep, containing pus and blood-corpuscles and epithelium, mostly nucleated. He passes in all about ℥ xxxv. in twenty-four hours. It has a slightly fishy odor, is neutral when voided, and rapidly becomes alkaline. Suspecting residual urine, I introduced a No. 9 catheter after he had passed ℥ iij. in his slow, dribbling manner, and drew off ℥ iv. more. On withdrawing the instrument, which encountered slight resistance and caused a little pain just as it was passing into the bladder, it was followed by a drop of blood.

On careful examination of the neck of the bladder from the rectum, *I find no increase of size in the prostate, nor any alteration in its shape, consistence, or temperature.* The treatment was adopted of daily introducing a flexible catheter, and syringing out the bladder with tepid water, which was followed at once by improvement in the character of the urine and diminution of the frequency of the calls. I found the urine clearer, faintly acid, and almost natural in odor for the rest of the day after the injection; but the next morning the same proportion of residual urine was found, with the usual fishy smell. At the end of a month this amount of improvement was established, but nothing further. Meanwhile I had satisfied myself that there was no paralysis of the bladder, and had several times carefully examined the patient for calculus, without result. I was suspicious on this point, for he had several times passed small soft masses of yellowish-white gravel, which I ascertained to consist of a mixture of the phosphates of ammonia, magnesia, and lime; previous to voiding them, he suffered increased irritation of the bladder. The patient was then taught to use the catheter for himself, and directed to draw off his urine and inject the bladder twice in the twenty-four hours. This was again followed by improvement; but at the end of some months he was almost as bad as at first. The difficulty of voiding the urine had somewhat increased, and on one or two occasions he had retention. In addition to this, the conical probe-pointed flexible catheter which he used was passed with increased difficulty and pain, and sometimes could not be passed at all. Under these circumstances, recognising that the patient's inability to void his urine in the natural way was irremediable, and that his constant straining was evidently keeping up and aggravating his cystitis, and having made up my mind that the whole cause of trouble was "centric hypertrophy of the prostate," with a probable development of the "third lobe," which acted like an obstructive valve, and that it was increasing (although there was still no enlargement to be felt from the rectum), I determined that he should relinquish all effort to pass water through the urethra, and rely entirely upon the use of a properly-curved catheter whenever the desire occurred. He accepted this conclusion with some reluctance, and I had some trouble in drilling him in the use of the instrument; but finally he acquired the knack of passing a Weiss' catheter No. 5, with a short, sharp, and extreme curve, and has done so about five times in the twenty-four hours for the last nine months without pain or failure in a single instance. He still uses the warm-

water injection once or twice a day; his cystitis has almost disappeared; his urine is clear and uniformly acid; his weight and general health have returned to their former standard, and he is satisfied that he has found the only effective remedy for his disease.

I have digested and condensed this case from my note-book, where I kept a full record during its progress, and believe that it presents a correct picture of the disease to which Mr. Thompson has given the correct designation.

A CASE OF

COMPLICATED DOUBLE HARE-LIP AND CLEFT PALATE,

SUCCESSFULLY OPERATED ON

By GURDON BUCK, M.D.,

SURGEON TO NEW YORK HOSPITAL, ETC., ETC.

Harriet Quinn. æt. eight years; Winsted, Conn. Admitted March 16, 1865, into New York Hospital.

A double fissure traverses the roof of the mouth, on either side of the septum nasi, and splits the velum and uvula.

The cleft of the upper lip is also double, with a central tongue-shaped portion of the lip suspended from the columna nasi. and interposed between the clefts.

The division of the orifice of the left nostril is complete; the ala of this side yawns widely open. The ala of the right nostril is still held *in situ* by a small band of integument fastening it to the septum.

Fig. 1.

An intermaxillary bone, supporting three incisor teeth (the two middle and left lateral), stands out prominently from the space between the two nasal fissures, and is continuous above with the septum, which affords it its only support.

This salient projection is covered by the central tongue-shaped portion of lip already described, and constitutes a revolting feature in the deformity. It is deflected from the median plane to the right side, and its margin is in contact with the corresponding margin of the cleft of the maxilla. This deflection shuts off the view into the right fissure, while it exposes widely the view into the left. The teeth occupying the intermaxillary bone stand out irregularly. The inferior margin of the septum is thin posteriorly, and grows thicker as it advances forward, and expands into the intermaxillary bone.

All the parts involved in the malformation present a healthy aspect, and both halves of the upper lip are supple and extensible.

Operation.—*March* 18, 1865; 12 *o'clock.*—Patient being etherized, the following operation was performed: —

The central tongue-shaped portion of the upper lip was dissected up to its junction with the columna nasi. The intermaxillary bone was excised horizontally on a line with the inferior edge of the cartilaginous portion of the septum. The tongue-shaped appendage was then brought down to cover the fresh-cut margin of the vomer, and its edges being squared, were stitched on either side to the mucous membrane covering the vomer. By this means the columna was lengthened out to its full dimensions.

The next step of the operation consisted in detaching the two halves of the lip extensively on either side from the bone, and preparing the opposite edges of the cleft for coaptation. This was done as follows:—The lip being held upon the stretch, was dissected up freely from the ascending nasal process of the superior maxilla, and outward from the neighboring bony surface, as far as the last molar tooth. This being done on both sides, permitted the opposite edges of the cleft to be brought readily into contact below the septum, and without tension. As the anterior extremities of the upper maxilla, which form on either side the boundaries of the bony cleft, projected far beyond the line of the dental arch, they required to be reduced into place. This was done by cutting through the bone transversely, high up on the palatine surface of the alveolar arch, with Butcher's forceps, and then seizing the projecting part with flat-jawed forceps, and crushing it down into

Fig. 2.

place. Both sides being treated in this way, the bony cleft was narrowed, and the approximation of the two halves of the lip greatly facilitated.

The edges bordering the cleft in the lip were next prepared. The angle on either side was seized with clawed forceps near its vermilion border, and held tense while the lip was transfixed at the point seized, and the section carried upwards to where the lip joined the ala nasi. Both strips were brought down with their cut edges facing each other, and traversed with a coarse thread which served to hold the newly-cut edges of the lip even, and facilitate the introduction of the sutures.

The first suture, which was a pin suture, was introduced at the vermilion border, and wound with yarn. The second, also a pin suture, was inserted high up close to the septum, and secured in the same way. Two interrupted thread sutures were inserted between the pins. The strips which had been pared as above mentioned,

were shortened so as to leave a pouting projection at the vermilion border; three fine thread sutures were inserted to secure them in coaptation. The alæ nasi, which were compressed by the approximation of the two halves of the lip, were somewhat relieved by an incision circumscribing them, and extending through the entire thickness of the integument and mucous membrane. Considerable hæmorrhage unavoidably occurred, but only a single vessel required a ligature. No adhesive straps were used. Water dressings were freely applied to the face; stimulants administered *pro re nata*. Patient to take Liquor opii comp. gutt. x. Draught rejected. At 7 P.M., Liq. opii comp. gtt. v., repeated at 12; midnight, gutt. x.

March 19.—Slept well. This morning somewhat feverish. Pulse 120. Ord. Spir. Minderer ʒ ij., ℥ q. h. Yarn removed from pins, and fresh yarn reapplied. Moderate amount of swelling in both cheeks. Considerable redness of right cheek. Cap. Elixir Opii McMunn gutt. x. at bedtime.

March 20.—Rested well. Swelling of cheeks subsiding. Redness of right cheek diminishing. Sal. Rochelle ʒ ij. administered to move bowels, Fresh yarn applied to pins. One suture removed from the lower portion of the wound.

Cast of Mouth, before Operation, in Profile.

March 21.—Improving. Still feverish. Pulse 120. Bowels have not moved. Redness of cheek nearly gone. Swelling subsiding. Omit Sp. Mind. Ulceration beginning about the pins. The lower pin was removed, and fresh yarn applied to the upper pin. Elixir McMunn gutt. x.

March 22.—Doing well. Bowels have moved freely. Patient less feverish. Skin cool. Pulse 112. P. M.—Upper pin removed. Sutures removed from the vermilion border of lip. Adhesive straps applied from one cheek to the other, to afford lateral support. Patient irritable. Cap. Elixir McMunn gtt. v., ℥ q. h.

March 23.—Swelling of left cheek subsided; that of right increased a little, with slight redness. Continue water dressings. P. M.—Remaining sutures removed. The newly cicatrized upper portion of the wound has slightly yielded under the tension resulting from the swelling of the cheek. To counteract this a single thread suture was introduced high up, and a patch of three thicknesses of adhesive plaster inserted under the knot. Adhesive straps reapplied so as to afford lateral support. Omit. Elixir McMunn.

March 27.—Improving. Suture removed from lip. Straps reapplied.—*April* 2.—Patient about the ward. Alæ of nose disposed to flare out.

April 21.—The parts have entirely healed. A slight notch has gradually developed itself at the middle of the vermilion border of the upper lip, where the two halves unite, owing to the unavoidable shortening of the perpendicular cicatrix which unites the two halves.

The pressure of the left half of the lip upon the only remaining incisor tooth keeps up ulceration and swelling of the mucous membrane. To relieve this, the tooth was to-day extracted by Mr. Bishop, dentist.

Both alæ of the nose are still disposed to flare out; to correct which, a plug of lint is kept in each nostril by a strip of adhesive plaster, applied from one side of the nose to the other, over the protruding plugs.

Patient was discharged, with the promise to return to the hospital early in June for further examination.

August 22.—The illustration (Fig. 2), from a photograph taken at Winsted several weeks after she left the hospital, shows a great improvement in her appearance.

CASES OF

LOSS OF SPEECH, OR APHASIA,

AS CONNECTED WITH HEMIPLEGIA, WITH REMARKS.

By AUSTIN FLINT, M.D.

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE, BELLEVUE MEDICAL COLLEGE, N. Y.

The term *aphasia* has recently been proposed by Trousseau to denote loss of the power of speech occurring without inability to perform the movements involved in the utterance of language, and without any lesions of the organs of phonation. This term appears to be generally accepted in lieu of the terms *alalia* and *aphemia*, which have been used in a similar sense. Loss of the voice, as a consequence of either laryngeal disease or paralysis, affecting the spinal accessory nerve, is denoted by the term *aphonia*. Loss of power to pronounce words arises from inability to produce or coordinate the movements necessary to articulation. The difficulty in aphonia is independent of these affections; the voice is not lost, and the control over the muscles of the tongue and lips is preserved, but the patient is mute from an inability to use words expressive of his ideas. The difficulty consists in the loss of memory as regards language. In extreme cases this loss of memory is total, the patient being absolutely dumb; but the difficulty in some cases is manifested by more or less impairment of speech without complete mutism. Moreover, the loss of speech is not in consequence of the absence or confusion of ideas. Patients affected with aphasia may understand perfectly what is said to them; they may be able to read; and, in some cases at least, there does not appear to be deficiency of intelligence.

The attention of clinical observers has recently been directed to this affection. Within the past few months it has been under discussion in the Academy of Medicine in Paris, and reports of cases have appeared in some of the British medical journals. The difficulty relating to the intellectual faculty involved in speech, clinical researches have seemed to bear upon the localization of this faculty. All observers agree that the affection, in the great majority of cases, is associated with hemiplegic paralysis, and that the paralysis, as a rule, is on

the right side of the body; hence, it has been inferred that the faculty of speech is seated in the left hemisphere of the brain. A French observer, Dr. Dax, appears to have collected the largest number of cases, viz. 140, in which the paralysis was on the right side.* It is intimated, however, that some of these cases were not cases of veritable aphasia. Dr. J. Hughlings Jackson, of London, has reported 34 cases, of which in all but three the right side was paralysed.† In a large proportion of these cases cardiac murmur coëxisted, a fact which the reporter considers as tending to show the probable production of the paralysis by embolism. According to Trousseau, in the immense majority of cases there exists softening of the brain. The affection, however, is not invariably associated with hemiplegia; that is, it may be independent of paralysis: and that it may exist without softening or other structural lesions is rendered probable, not only by the fact just stated, but by the complete recovery from the paralysis in some of the cases in which the latter coëxists.

During the past five years six cases of aphasia have fallen under my observation at Bellevue Hospital, some of which have been presented at my clinic in the hospital amphitheatre. I propose in this article to give a brief account of these cases, hoping that I may in this way lead other clinical observers in this country to report cases, and thus contribute to the accumulation of facts for the elucidation of the affection. Of the six cases, one case at the present time remains in hospital, and another, having been under observation for several weeks, has just been discharged. Of two of the remaining cases I have preserved notes, and my account of the other two cases must be given from recollection.

Case 1.—This case came under observation in 1861. The patient was a female, aged about 35. She had been in the hospital for several months. She had entered with hemiplegia, from which she had nearly or quite recovered, and she was employed as a helper in one of the female wards. She was speechless, except that she uttered the word *yes*. This word she pronounced distinctly, and she invariably utte ed it whenever she attempted to speak. She was not devoid of intelligence; on the contrary, she was bright and active, doing the duty of a ward-helper as efficiently as any one in the same capacity in the hospital. Much effort was made to teach her to pronounce other words than the one which comprised her vocabulary, but in vain. She left the hospital without any improvement as regards speech, and her subsequent history is unknown. I am unable to state whether the hemiplegia affected the right side in this case.

Case 2.—The patient in this case was a male, aged about 35. He entered the hospital with hemiplegia, which was nearly complete. The aphasia was complete, the patient being unable to utter a word. He recovered from the hemiplegia so as to walk about, but there was no improvement as regards speech, and he was discharged after having been in hospital several weeks. I am unable to state in this case whether the hemiplegia affected the right side. The patient appeared to be intelligent, and passed much of the time with a book in his hand, appearing to read; he evidently understood everything that was said to him. On being requested to write, he made the attempt, but the result was a jumble of lines from which nothing could be made out.

Case 3.—The following condensed account of this case is given from notes made at the time the case was under observation:

J. P., aged 34, was admitted November, 1861. It was ascertained from friends that on the day prior to his admission he appeared to be well, but he complained of palpitation on going to bed. On the morning of the day of his admission he was found to be hemiplegic and speechless. The hemiplegia was on the right side, and was complete. The face was not disturbed. The tongue was deflected to the right side. Intelligence appeared to be intact. He protruded the tongue readily, but was unable to speak. The heart's action was rapid and irregular, but there was no cardiac murmur, and the size of the head was normal.

Nov. 30.—When the ward containing this patient passed into the hands of one of my colleagues, considerable improvement had taken place. He had recovered a certain amount of power over the paralysed limbs, and he seemed quick and bright as regards intelligence, but the aphasia remained complete; he evidently comprehended everything that was said to him, but he was unable to utter a word.

Dec. 5.—The hemiplegia had nearly disappeared, and the patient appeared to be well in every respect save the loss of the power of speech. When asked why he did not speak, he put his finger to his lips and shrugged his shoulders. Shortly after this date he was discharged.

Case 4.—G. W., aged 50, was admitted Oct. 2d, 1862. His wife stated that he was suddenly attacked with hemiplegia in Jan., 1863. For two years previous to this attack he had complained from time to time of pain in the head. He recovered from the paralysis in a short time sufficiently to return to his occupation, which was that of a roofer. In February he had an apoplectic seizure, with a return of the hemiplegia on the same side as before, viz. the right side. When admitted, he had sufficient power over the lower limb to walk, but with a halting, unsteady gait. The upper limb was completely paralysed. There was no want of power over the muscles of articulation, and he appeared to understand fully everything said to him; but he was only able to utter the word *yes*, which he invariably uttered whenever he attempted to reply to questions. There was no improvement as regards the aphasia up to his death, which occurred Dec. 11, 1865. His death was occasioned by an attack of pneumonia.

On examination after death, the anterior surface of the left hemisphere of the brain presented two depressions situated near each other, each occupying an area of the size of a half-dollar. Within these spaces the brain-substance was of a pulpy consistence. The softening extended to the left corpus striatum. There was no appearance of extravasated blood here or elsewhere. There was no appearance of meningitis. The vessels near the softened portions, examined microscopically, were found to be healthy. The heart was free from lesions.

Case 5.—S. F., aged 34, was admitted July 21st, 1865. The previous history was not ascertained. When admitted, hemiplegia affecting the right side was nearly complete. He began shortly to improve as regards the paralysis, and after a few weeks was able to walk about. He was discharged Nov. 18, 1865. He was then able to walk with but little difficulty, but the upper limb still remained considerably paralysed. The aphasia in this case was not complete. The patient could say *yes*, *no*, and *I don't know*. These words comprised his vocabulary. The intelligence seemed to be intact; he understood everything that was said to him. An aortic regurgitant murmur existed in this case, the heart not being much, if at all, enlarged.

Case 6.—S. M., aged 63, was admitted Sept 17, 1865, and is still in the hospital. The previous history in this case has not been ascertained. The right side is incompletely paralysed; the patient is able to walk about

* Archives de Medecine, Jan. 1865, and London Lancet, Aug. 1865.
† Clinical Lectures and Reports, London, 1861; and Archives de Medecine, March and April, 1865.

with a crutch. There is no cardiac murmur. The aphasia is partial in this case. The patient is able to utter a considerable number of words, but he is unable to express his thoughts or wishes. He begins a sentence, and after trying to recall words, he says, "I can't," "I can't." He is able to repeat words directly after they are pronounced by another, but in a moment he forgets them. He understands what is said to him, but his intellect seems to be weakened.

As regards the side affected with hemiplegia, I am unable to state the fact in two of the foregoing cases. In the remaining four cases, the hemiplegia affected the right side. Does it follow from the great preponderence of the cases of aphasia, in which the right side is paralysed, that the mental faculty of speech is to be *localized* in the left hemisphere of the brain? Irrespective of the improbability of the faculty being seated in either hemisphere to the exclusion of the other, this question is to be answered negatively, in view of the fact that aphasia does occur in cases of hemiplegia affecting the left side, although the number of such cases is comparatively few. Were the faculty of speech seated exclusively in the left hemisphere, there should be no exceptions to the rule of the hemiplegia being on the right side. The situation of the hemiplegia on the right side, in the great majority of the cases of aphasia, is, however, a striking fact, which, of course, has an adequate explanation. Autopsical researches may show that the loss of speech depends on a particular situation, in either hemisphere, of the morbid conditions giving rise to the paralysis; and that, for reasons at present unknown, this situation is more likely to be involved when the conditions are seated in the left than in the right hemisphere. In the only one of the six cases in which an autopsy was made, there was circumscribed softening of the anterior lobe of the left hemisphere, the softening extending to the superficies. So far as this case goes, it sustains the statement of Trousseau, that in aphasia there generally exists softening.

In all these cases the aphasia persisted without any improvement. So far as these cases go, they do not afford encouragement to expect the return of the power of speech, even when recovery from the hemiplegia is nearly complete. Recovery from aphasia does, however, sometimes take place. I have met with an instance of incomplete aphasia, in private practice, associated with transient hemiplegia, in which, after a few days, the memory of words returned. A case of recovery from complete aphasia, with hemiplegia, is reported in the *Buffalo Medical and Surgical Journal* for November, 1865, by Dr. Conger. Trousseau and others have reported cases of recovery.

In cases of persistent aphasia it is not easy to determine to what extent the mental faculties are preserved, aside from the memory of words. The ability to comprehend freely what is said, and sufficient intelligence to perform routine duties, are certainly not incompatible with the loss of speech; but it is extremely difficult to ascertain the mental condition as regards the reasoning powers, judgment, and sentiments. Trousseau is of opinion that the intelligence is always impaired to a greater or less extent. With reference to this point of inquiry, further study of the affection is desirable. The affection, in this aspect, has an obvious and important medico-legal bearing.

Personal.—Dr. Jas. P. White of Buffalo, New York, sailed recently for Europe, with the intention of being abroad for eighteen months. Dr. Henry M. Lyman of Chicago, and formerly of this city, has become one of the editors of the Chicago *Medical Journal.*

THE GUTTA-PERCHA SHOE IN THE TREATMENT OF TALIPES.

By ALFRED C. POST, M.D.,

PROFESSOR OF PRINCIPLES AND PRACTICE OF SURGERY, UNIVERSITY MEDICAL COLLEGE, N. Y.

About sixteen years ago I was treating a little girl for talipes varus, with a modification of Scarpa's shoes, which I was then in the habit of employing, when troublesome ulceration of the integument occurred from the pressure of the straps which were used to secure the shoes upon the feet. It was evidently a matter of necessity to omit for a time the use of the shoes, until the ulcerated surfaces should have an opportunity to heal. I was much chagrined by the prospect of a long delay in the treatment, especially as the patient resided in the country, and it was quite inconvenient to the parents to keep her for a long time in the city. I was led to reflect on the best means of preventing a return of the deformity towards its original condition, during the period when I should be obliged to suspend the use of Scarpa's shoes. It occurred to me that a splint or shoe of gutta-percha might be applied in such a manner as to maintain the improvement which had already been gained by the treatment, if not to make some further advance towards a cure of the deformity. I accordingly contrived and applied such an instrument, keeping it in place by means of a roller bandage. I found that by this means the feet could be maintained in a good position, with very little inconvenience to the little patient; and under appropriate dressings, the ulcerated surfaces soon healed. To my surprise, the deformity yielded more readily to the new treatment than it had done while Scarpa's shoes had been worn, and I felt no disposition to return to the use of the spring shoes after the ulcers had healed. From my experience of the benefits of the simple contrivance which I had used in the case just alluded to, I was induced to employ it in similar cases which were presented to me; and the results were so entirely satisfactory, that I have ever since employed shoes or splints of similar construction in the treatment of infantile club-foot, in preference to the spring shoes which surgeons ordinarily employ for the same purpose. The material which I ordinarily use in the construction of these shoes is a gutta-percha sheet from a sixteenth to an eighth of an inch in thickness. It is cut of such a shape as to adapt itself to the sole and sides of the foot, leaving a space uncovered on the dorsum of the foot equal to about one-third of the breadth of the foot; it is also adapted to the sides of the leg, extending up two-thirds of the distance to the knee, and leaving a narrow space uncovered before and behind, each space so uncovered being about one-sixth of the circumference of the leg. The material is readily moulded to the shape of the limb, by immersing it for a few seconds in water, at a temperature of 100° Fahrenheit. I am in the habit of moulding the shoes thus heated, over a wooden last made for the purpose. The last is not made after the fashion of a bootmaker's last, but it is shaped like the natural leg and foot, except that the outer side of the foot is made to correspond with the inner, thus obviating the necessity of having separate lasts for the right and left foot. I have sometimes used similar shoes made of felt stiffened with shellac, as manufactured by Dr. Ahl, of Southern Pennsylvania. In order to mould the felt, it must be dipped in water at nearly a boiling temperature, and the hands require to be protected by means of cotton gloves wet with cold water. I am rather inclined to prefer the gutta-percha shoes to those which are made of felt, es-

pecially as the former material is more conveniently moulded to its proper shape.

I generally commence the treatment of infantile club-foot by the subcutaneous division of the tendo-Achillis, after which I apply a strip of isinglass plaster over the small wound of the skin. I then have the foot held by an assistant as nearly as possible in its normal position, and while it is so held, I careful'y apply a roller bandage so as to cover the foot and leg, beginning the application on the outer side of the ankle. I then apply the gutta-percha shoe, an assistant grasping the leg with one hand, pressing the upper part of the shoe against the sides of the limb, and with the other hand pressing the sole of the shoe against the sole of the foot. While the shoe is thus firmly pressed against the leg and foot, I apply a roller bandage firmly, so as to secure it in its place. After the lapse of twenty-four to forty-eight hours, I take off the bandages and shoe, wash the foot, wipe it dry, use passive motion freely in different directions, and then reapply the apparatus as before. The application is repeated at intervals of two or three days, until the foot is brought to its proper shape, when it is put up in a laced boot, lacing to the toes, and

having a firm sole and stiff sides, provided with iron braces which extend nearly as high as the knee, and secured by a strap and buckle around the upper part of the leg.

The following are, in my estimation, the advantages of the gutta-percha shoe over Scarpa's shoe, and its various modifications:—

1st. Its greater simplicity, and the ease with which it is made. When the material is at hand, the shoe can readily be made in fifteen minutes.

2d. It is much cheaper than the spring shoe.

3d. It is more comfortable to the patient, being lighter, exerting a less injurious pressure, and being less likely to be kicked off by a restless child.

4th. It is much less likely to occasion excoriation or ulceration of the integuments.

5th. It expedites the cure, giving a better support to the foot, and bringing it more readily into its normal position.

The annexed woodcut exhibits a view of the gutta-percha shoe, and of the last on which it is moulded.

M. Jobert de Lamballe is suffering under mental derangement, which has necessitated his confinement in a lunatic asylum.

BLEPHARITIS CILIARIS AND PHLYCTENULAR CONJUNCTIVITIS.

By E. WILLIAMS, M.D.

PROF. OF OPHTHALMOLOGY AND AURAL SURGERY, MIAMI MEDICAL COLLEGE, CINCINNATI, OHIO.

It is not my purpose to give a lengthy description of these common and well known diseases, but to call attention to some practical points in their treatment. Still, a hasty sketch of their characteristic features will facilitate a better appreciation of the therapeutic measures which I wish to present. Whether associated, or existing separately, blepharitis ciliaris (sometimes called blepharitis marginalis—bleparadenitis—tinea tarsi) and phlyctenular or pustular conjunctivitis occur usually in early life and in the same class of patients. The period of life at which they are most frequent is from the second to the fifteenth year. If they are seen after that age, it will generally be found to be but a continuation of the same affection from an earlier period. Children of a strumous or scrofulous diathesis are the almost exclusive victims of these maladies.

Strictly speaking, blepharitis ciliaris, as the name intimates, commences in the individual follicles of the eyelashes, and invades the other textures of the lids subsequently. It is an inflammation of those follicles followed by little abscesses, of which the cilia form the centres. These minute collections of pus become confluent along the edge of the lid, agglutinating the lashes in little tufts, and forming scabs or crusts as they desiccate. These adhere very firmly, and when removed forcibly, produce pain, often bring away some of the hairs, and the surface beneath is found to be raw or ulcerated—perhaps bleeds. These patches of disease may be limited, or extend the entire length of the lid. When this local difficulty has lasted for some months or years, the bulbs of the lashes are gradually obliterated, the hairs fall out, grow in a stinted form, or cease altogether; giving rise to that thickened, red, perhaps partially everted state of the edge of the lid, called *lippitudo*.

Blepharitis ciliaris, when once well established, usually persists for years, or for the remainder of life, if cleanliness and favorable hygienic measures are impracticable or not enforced. The amount of redness, swelling, and soreness of the lids varies very much under special provocations or favorable circumstances. The smouldering fire at the roots of the lashes, however, never ceases; and that is the focus from which they flame out. Intercurrent attacks of phlyctenular conjunctivitis often complicate and aggravate the difficulty; and not very unfrequently, in the chronic forms, there is set up blennorrhœa of the lachrymal sac, with its consequences. On the contrary, blepharitis marginalis may, in its turn, be provoked and perpetuated by dacryocystitis, stricture of the nasal duct, and dilatation of the sac. Now these conditions mutually aggravate each other, and the necessity of embracing them all in the treatment is self-evident. Eczema and other eruptions about the face and head, and especially in and around the nostrils, causing a constant running, with redness and thickening of the nose, or the formation of scabs, are likewise a very frequent and troublesome complication.

Phlyctenular conjunctivitis (often called scrofulous ophthalmia), is marked by symptoms so peculiar as not to require a tedious description. It is a partial inflammation, commencing in the conjunctiva of the globe, and attended by pustules or vesicles. These so-called phlyctenulæ are most commonly seated on the line of junction of the cornea and sclerotica, but sometimes they are seen entirely on the one or the other of these structures. They are inflammatory accumulations of

serum or of pus under the epithelial layer of the conjunctiva, and when located on the cornea are designated phlyctenular keratitis. These may be absorbed without rupturing, but generally the elevated epithelium bursts and leaves superficial ulcers, called on the cornea, facetted ulcers. In favorable cases they then heal, by being first covered with a new epithelial layer, that makes them appear shiny and smooth in the bottom, and a subsequent reproduction of the deeper layers. On the cornea they leave little circular depressions, readily seen by looking obliquely at them, which persist a very long time before they are filled to a level with the general surface. If the ulcer extends deep into the lamellæ of that membrane, permanent, or at least long persisting, white specks or opacities are left behind. When situated towards the centre of the cornea, and a bundle of vessels develops under the epithelium, running from the conjunctiva scleroticæ to the pustule, lymph often exudes in a narrow strip along the course of the vessels, leaving a concentric opaque streak in the cornea. In some cases, on the other hand, a series of vesicles following from the margin towards the centre, are produced, attended by the gradual pushing forward of the little loops of vessels, and leaving when they subside the same riband-like opacity just mentioned.

So long as the phlyctenulæ are confined to the conjunctiva scleroticæ, there is seldom any marked intolerance of light or other suffering. But when they come out on the cornea, especially if near the centre, they nearly always give rise to extreme photophobia, profuse lachrymation, and sometimes severe pain. The intolerance of light is so intense often, that the little sufferers seek the darkest corners, lie on their faces and bury their eyes, covered with their hands, in a pillow or anything they can get, so as, if possible, to exclude every ray of light. This confines the perspiration, heats the eyes, aggravates the eruptions of the face, and is in all respects the most distressing symptom, lasting frequently for weeks together before any light can be endured. This feature of the disease is more marked in the morning, giving way towards evening, so that after sundown the child may open its eyes better. This excessive tenderness to light, resulting in reflex, spasmodic contraction of the orbicularis palpebrarum, and profuse lachrymation, is the result, in my judgment, exclusively of irritation of the corneal filaments of the fifth pair of nerves. Whenever I see these delicate, scrofulous children, with their eyes covered and spasmodically closed, I am certain that they have corneitis with little specks or ulcers. Still I always insist on holding the child's head between my knees, with its face up, and forcibly opening and examining the eyes, so as to see the exact state of the cornea. This is less cruel and also less *irritating to the mother*, than plunging the child's face in ice-water, as recommended by Graefe, and others.

In extreme cases chloroform may be used, but I seldom find it necessary. The photophobia is frequently out of all proportion to the amount of local trouble; but there is always some deposit in the cornea, or abrasion of its surface, which can be detected by a proper inspection.

It is comparatively seldom that these phlyctenulæ give rise to ulcers that invade the deeper layers of the cornea; but sometimes this occurs. The edges and bottom of the ulcer then become infiltrated with a dirty white or yellowish-colored deposit, which, as it goes deeper and deeper, becomes complicated by hypopium, and eventually, if not properly treated, results in perforation and prolapsus of the iris. This tendency to deep ulceration and perforation of the cornea in pustular conjunctivitis, is sometimes epidemic. A few months ago, some seventy or eighty children in one of our neighboring orphan asylums, were attacked within a few days with this disease. Rapid ulceration, hypopium, and perforation took place in many of them, and several were blinded in one or both eyes before any treatment was thought of. Some of them had had granulated lids previously, and some had not. The affection assumed the form of general catarrhal conjunctivitis, with large sloughing phlyctenulæ, which were not influenced by anything but repeated paracenteses of the cornea, atropine, and compression with cotton and an elastic bandage.

In the treatment of this class of diseases I have used for the last eight years a preparation, not found in any of our books, which is so uniformly and promptly beneficial, that I have abandoned all the other mercurial local applications in its favor. When *opportunely* and properly applied, it acts like a charm, and patients or their friends nearly always come back, if they ever have another attack, and ask for some more of that *brown salve*. The formula for its preparation, I found in a foot-note in an old edition of Wilde on the Ear. He recommended its use very highly in chronic diseases of the dermoid lining of the meatus auditorius externus. It occurred to me that its peculiar properties might prove useful in the diseases under consideration. I tested it extensively and faithfully, and it has far surpassed my most sanguine expectations. I call it the *brown citrine ointment*, and write it Unguent. citrin. rub. At my request, Mr. A. Fennel and Prof. E. L. Wayne, well known chemists and druggists of this city, have experimented in making the ointment till they have very much improved its quality. The original formula was the same as that of the U. S. Pharmacopœia for the preparation of citrine ointment, excepting that cod-liver oil was substituted for the axungia and the neatsfoot oil. Still it was somewhat granular and coarse, till Prof. Wayne finally succeeded by *reheating*, and then stirring till it was cool, in making a dark mahogany-brown salve of uniform consistence, tenacious, and readily melting with the temperature of the body. When rubbed on the lids or applied to the conjunctiva, it melts in a few seconds, spreads and adheres a long time to the lids, or, if used in the eye, is rapidly diffused over the ball by the movement of the lids, with *very little irritation*. It can be used in its pure state, and does not need to be *removed* afterwards at all. My treatment for blepharitis ciliaris is very simple. The first thing on which I always insist, and without which no treatment does much good, is to keep the edges of the lids *absolutely free from scabs or scales*. I have the eyes bathed with tepid water morning and evening, till the scabs are soft and can be readily scraped off, or rubbed off with a soft rag. If there is much rawness and soreness of the margins of the lids, I trim off the lashes with a fine pair of scissors, as close as possible. This is much better than pulling them out, as recommended by some authors; and when so trimmed, it is much easier to keep the lid free of scabs. If the lids are swollen and very sore, I have them poulticed every night for a few days; and sometimes when there are ulcers or raw places along the roots of the lashes, I touch them lightly for a few times, at intervals of two or three days, with a point of nitrate of silver. Every night, after the washing and cleaning, the salve is rubbed well along the edges of the lids with the finger. If it irritates and causes the skin to puff up and look redder next day, which it rarely does, the patient may omit the use of it the next night; otherwise, it should be applied every evening at bedtime. Its continuance two or three times a week for several weeks or months after the disease is entirely relieved, should be urged, to prevent a relapse. If there is much conjunctivitis, I

prescribe a solution of four grains of sulphate of morphia, and half a grain of sulphate of copper or zinc, to the ounce of water, dropped into the eye three times a day. Internally, such patients should always take iron or tonics of some kind. I usually give the Liquor ferri iodidi, in doses suited to the age of the subject, and keep it up for several months, to secure a *radical result.* Of course, regular exercise in the fresh air, good nourishing diet, bathing followed by friction, and the avoidance, as far as possible, of all causes of irritation, are important hygienic measures in this class of diseases.

In phlyctenular conjunctivitis, where the vesicles have their seat on the conjunctiva scleroticæ, or being on the cornea, give rise to but little intolerance of light and lachrymation, this salve again is most valuable. A portion of it, say a small drop, should be put from the end of a knitting-needle or probe, between the lower lid and the ball and the upper lid, then moved up and down a few times till it is spread freely over the cornea. This ought to be done at bedtime. The larger portion of the salve is soon washed and pressed out on the edges of the lids, and, if blepharitis exists, can be usefully rubbed along the margin; otherwise it may simply be wiped away. If the conjunctivitis is more general, and there is much mucous secretion, I direct the astringent given above; otherwise, the ointment alone suffices perfectly.

Phlyctenular corneitis is treated in the same manner, when the acute symptoms have begun to abate, or when it assumes a mild form from the start. If there is marked dread of light, spasmodic closure of the lids, and epiphora, a few days of preparatory treatment are necessary. For the relief of the photophobia and other symptoms arising from acute inflammation of the cornea, there is nothing equal to the local application of a solution of atropia. In a child from two to five years old, I prescribe a solution of gr. j. to aquæ ℥j., to be dropped into the eye from three to six times in the 24 hours, according to the intensity of the symptoms. If they are over five years old, a two-grain solution may be directed. Internally, the sulphate of quinine in very liberal doses, say from one to two grains, even more where the photophobia is extreme and obstinate, three times a day, with the solution of sulphate of atropia locally, nearly always overcomes these distressing symptoms in a few days. If the quinine alone does not subdue the intolerance of light, I combine opium with it, giving from half a grain to a grain with the quinine three times a day. Under this treatment, the child begins to open its eyes and bear the light better in a short time. It is astonishing what effect the atropia has in quieting the eye and allaying the inflammation. When the acute symptoms have decidedly abated under this treatment, the salve in the eyes once a day may be tried, and, if well borne, kept up for several weeks. It then not only allays irritation, and favors the healing of the phlyctenulæ, but promotes the absorption of the remaining opacities. After the first few weeks the quinine may be left off, or continued in smaller doses, in combination with iron; or, what is preferable, the iodide of iron may be substituted for it. When the acute symptoms and redness of the eyes are relieved, the atropia also may be suspended, and the case left to the use of the salve alone.

The eczema and other eruptions about the face, should be smeared every night with the same ointment. It acts very promptly in relieving all scabby eruptions on the face, head, and elsewhere. Instead of fearing to heal these up, I always try to get rid of them—especially the sore nose, which keeps the eyes irritated and protracts the cure—as soon as possible. Blisters and counter-irritants of all kinds should be strictly avoided, as doing no good and increasing the eruption of the face. Should the disease of the cornea assume the form of deep ulceration and hypopium, the energetic use of atropin, the compressive bandage, combined with paracentesis corneæ once a day, have yielded far better results than any other means that I have tried. The paracentesis often checks the progress of the ulcer immediately, and prevents perforation; or if it does not prevent perforation, it limits the lateral extension of the ulcer, and thus helps to save the cornea. I generally puncture the cornea once a day, under chloroform if necessary, for several days, till the hypopium and extension of the ulcer are relieved. I puncture the cornea to evacuate the aqueous humor and relieve tension, without regard to the pus. After the paracentesis, the pus or lymph is rapidly absorbed. I select the outer part of the cornea for the operation, simply because it is most convenient. I cannot too highly recommend this little operation in all cases of hypopium keratitis, as recently described by Roser, Von Graefe, Weber of Darmstadt, and others. Where there is a distinct abscess of the cornea, Weber's recommendation to puncture through the collection of pus is sometimes preferable, but must be done with great caution, to prevent the too sudden evacuation of the aqueous humor. He enters the needle at the most dependent point of the pustule, and passes it obliquely through, so as to enter the anterior chamber at the upper part. The aqueous fluid thus washes out the abscess as it escapes, and the further subsidence of the pus between the lamellæ is prevented. As a rule, I much prefer puncturing away from the seat of the ulcer.

I would say, for the information of any who may wish to get a good sample of the brown salve, that it can be ordered in any quantity of Suire & Co., druggists, N. W. cor. 4th and Vine streets, Cincinnati. I will not consume space in the discussing of the merits of other forms of mercurial salves, powdered calomel, &c., in these affections. They are all useful when used with discrimination, but in my practice very much inferior to the brown salve. The use of a seton in the temple, in phlyctenular corneitis, as recommended lately in the Ophthalmic Hospital Reports (London), Vol. IV; part iii, by Watson, I have never tried, and probably never will. Dr. Pagenstecher, of Wiesbaden, in his Klinische Beobachtungen, &c., 1861, recommends a salve of the amorphous yellow oxide of mercury very highly in the same cases. I tried it some years ago, but found it was very much more irritating than the brown salve, and less efficacious. In the *Ophthalmic Review* of July, 1865, is an excellent article from the pen of Dr. Pagenstecher, on the value of yellow oxide of mercury ointment, and the method of preparation and using. I have no doubt but he gives a candid and well formed opinion of its efficiency; but a comparative trial of the two preparations has led me to adhere to the brown salve as much preferable.

Fermenting Milk in Phthisis.—A European savan having observed that the peasants of certain Russian provinces where fermenting asses' milk was used as a beverage, were remarkably exempt from phthisis, has been trying experiments with a mixture of ass's and cow's milk in a fermenting condition, used as a drink by tubercular patients. To produce the fermentation he adds yeast to the milk, and the prepared drink he dignifies with the name of *galuxyme.* His patients begin with a small quantity, and gradually increase their daily allowance to four or five bottles. The effect is slightly exhilarating and somewhat laxative at first, and afterwards fattening. The consumptives get well, of course, as they do with all other remedies.—*Pacific Med. and Sur. Journal.*

Original Lectures.

A LECTURE ON

ACCIDENTAL PUERPERAL HÆMORRHAGE,

DELIVERED JAN. 19TH, 1866, IN

THE COLLEGE OF PHYSICIANS AND SURGEONS,

BY T. GAILLARD THOMAS, M.D.,

PROFESSOR OF OBSTETRICS AND DISEASES OF WOMEN.

THERE are three distinct periods at which the parturient woman is liable to an inordinate loss of blood; namely, during pregnancy, during labor, and for one month subsequent to that process.

This division is by no means an arbitrary one, but is demanded by the circumstances of the case, and required for convenience of study and lucidness of understanding. Even the limit of one month given to the third variety is based upon good grounds, for at the end of that time the heretofore hypertrophied uterus having undergone involution so far as to have arrived at nearly its non-pregnant state, any flow taking place thereafter is properly regarded as disconnected with the puerperal condition.

These three distinct periods divide puerperal hæmorrhage into three equally distinct varieties, viz.:

Hæmorrhage before labor.

Hæmorrhage during labor.

Hæmorrhage after labor.

The pathology and management, however, of hæmorrhage occurring during the latter months of pregnancy, and during labor are so identical that it would be a useless refinement to separate them in description. I shall therefore follow the example of Dr. Collins and others, describing those hæmorrhages occurring during the last three months of pregnancy, and during labor, under the same head; namely, of ante-partum hæmorrhage, thus distinguishing them from post-partum hæmorrhage.

I shall devote this lecture, however, to hæmorrhage occurring during, and not before, labor, merely premising the assertion that all the statements made concerning this variety will apply with equal force to that occurring in the last three months.

Source.—It may be safely announced as a rule, that whenever, during labor, a hæmorrhage occurs, it arises from partial separation of the placenta from the uterus, and consequent rupture of the utero-placental vessels. It is true that there are other sources from which such a flow may occur, as for example the vessels of the ruptured cervix, bulbus vestibuli, or funis; but these accidents are so rare that we need not embarrass and complicate the study of the subject by anything more than a mere mention of the possibility. It is evident, then, that to understand the pathology and treatment of these conditions, you must first clearly comprehend the anatomy of the placenta, upon the injury done to which the loss is due. Let me then very rapidly, and in a cursory manner, refresh your memories upon this point. You will recollect that when the fœtal ball, surrounded by its tufted or shaggy chorion, enters the uterus, these tufts or villi penetrate the utricular follicles; and soon becoming vascular by entrance of bloodvessels from the fœtal body, establish sanguineous relations between mother and child; for the maternal vessels situated between the follicles just referred to, rapidly enlarge and surround the tufts on all sides. At a later period this connexion becomes destroyed, except over a limited space, where it becomes much more perfect, and forms the placenta. This organ, when fully perfected, consists of large pouches formed by dilatations of the vessels of the uterine mucous membrane, supplied with blood by the curling arteries of the uterus, into which the fœtal tufts dip by inverting, as it were, their walls. Now if the entire placenta be ripped off from the uterus, the uterine vessels supplying it are at once closed by ligation from the uterine fibres which surround them. But if part of it only be separated, hæmorrhage takes place—1st, from the placental surface which has been lifted, blood entering at its attached portion, and pouring out at that which is detached; and, 2d, from the open mouths of the uterine vessels, which the uterus is not able, from partial placental attachment, to close by ligation.

Varieties.—Generally the placenta is so placed in the uterus that the os may dilate and the child be expelled without its separation being involved in these processes, and it will, under such circumstances, retain its position and the integrity of its attachment, unless some untoward accident, such as a blow or fall, occur to displace it. At other times, however, it is attached to one side of the cervix, or over the entire cervix, so as to prevent the dilatation of this part, through which the child cannot pass as long as it remains closed. Now as the os and cervix must be dilated to permit the passage of the child, and as their dilatation must, under these circumstances, to a greater or less extent, detach the placenta and rupture the utero-placental vessels, it follows, as a deduction, that hæmorrhage thence resulting is not produced by accident, but, *ex necessitate rei*, is unavoidable.

For these reasons, all hæmorrhages occurring during labor have been very properly divided into

1. Accidental hæmorrhage.
2. Unavoidable hæmorrhage.

The second variety, you perceive, is synonymous with placenta prævia, an appellation which defines the unfortunate location of the after-birth which produces it.

Leaving the subject of placenta prævia and its resulting unavoidable hæmorrhage for our next lecture, I will occupy you to-day with the consideration of that variety which is purely the effect of some accident, and which, like every other accident, might, under favorable circumstances, have been avoided.

ACCIDENTAL PUERPERAL HÆMORRHAGE.

Frequency and Prognosis.—You will, I imagine, get a much more correct idea of the frequency of accidental hæmorrhage, by an examination of the reports of one faithful observer, than by averaging a large number of cases collected in the loose and unreliable manner which ordinarily characterizes the accumulation of statistical evidence. Dr. Collins, during a mastership of the Dublin Lying-in Asylum of seven years, had 16,654 births occur under his supervision, and in this immense number only thirteen cases of this variety of flooding were met with; considerably less than one in a thousand.

Of the thirteen women thus attacked, two died, and both after serious operations: one after version, and the other after craniotomy, so that it is by no means proper to conclude that they died from the hæmorrhage. Of the children, one only was born alive.

Thus you will perceive that the accident is not of frequent occurrence, that the prognosis for the mother is good, and that that for the child is decidedly bad.

Causes.—The pathological state causing the flow is, as already mentioned, rupture of the vessels which pass from the uterus into the placenta. The causes which bring about such rupture are numerous, since any kind of violence sufficiently great for the separation of the placenta would accomplish it.

The chief are blows or falls.

Sudden uterine contraction from mental emotion.

Sudden shocks or succussions given to the uterus, as from laughter, vomiting, &c.

Dragging off of the placenta by shortness of the cord, or its repeated winding around the child's neck.

Placental apoplexy occurring near the periphery of the organ.

There are other and less frequent and conspicuous causes, but it would be useless to name them, since, as I have said, any accident which severs the utero-placental attachment would produce it.

Symptoms and Diagnosis.—As the prognosis and more especially the treatment of the two varieties of ante-partum hæmorrhage differ from each other very much indeed, it is of great importance that the accoucheur should determine at once as to which one he has to deal with, and that his decision be as far as possible positive and final. This he will in many cases do without difficulty, but sometimes he will have to remain in suspense for a short period until the progress of the case enlightens him and determines the point.

Denman on this point justly remarks: "Before there is some dilatation of the os uteri, be the discharge ever so profuse, and it may even at this time be excessive, I do not know that it is always possible to tell with certainty whether the placenta is present or not. It may indeed be conjectured that the placenta is there attached by the cushion-like feel of the cervix and lower parts of the uterus." He then goes on to remark how, even after dilatation of the os, a clot of blood may be mistaken for the placenta.

The only reliable means for determining the nature of the flow are these:

In Accidental Hæmorrhage.

(*a*) There will have been no ante-partum loss.
(*b*) Uterine efforts will diminish the flow.
(*c*) An evident cause will generally be found for it.
(*d*) The loss is not generally very profuse.
(*e*) The placenta cannot be touched.
(*f*) Os uteri will be natural to the touch.
(*g*) Placental murmur loudest near fundus.

In Unavoidable Hæmorrhage.

(*a*) There will have been hæmorrhage during the last month or months of pregnancy.
(*b*) Uterine efforts will increase the flow.
(*c*) No cause will be found for it.
(*d*) The loss is often sudden and profuse.
(*e*) The edge of placenta may be touched.
(*f*) Os uteri will be thicker than ordinary.
(*g*) Placental murmur loudest in one or other iliac fossa.

As a little reflection will readily explain to you why these two varieties should be characterized by their respective symptoms, I will not do more than enunciate them. Let me insist, however, upon the importance of an early and positive diagnosis, if such is within the range of possibility. Of all the symptoms mentioned, the presence of the placenta near the os is the most valuable, and this one you must thoroughly test. Do not be satisfied with temporizing with digital examinations if they are not sufficient, but explaining the necessity to your patient, place her quietly under the influence of an anæsthetic, and pass the entire hand into the vagina. If the os is dilatable, pass the index finger well up into the cervical canal, and ascertain to your full satisfaction whether you have or have not a case of placenta prævia to deal with. As a matter of course, if the rational signs point strongly to the supposition that the case is one of accidental hæmorrhage and there is no immediate danger, you would not expose your patient to the annoyance attendant upon this procedure; but far better would it be to err on that side, than by a culpable inactivity to remain ignorant of a point upon the knowledge of which so much will depend.

Treatment.—Accidental uterine hæmorrhage should be treated upon precisely the same principles which should guide us in the management of such an accident taking place in any other part of the body. This you may, at first thought, regard as too general a statement; but as we proceed you will perceive that, although from the nature of the locality from which the flow occurs, the means employed for developing the principles may differ, the principles themselves are identical.

Let us suppose, for example, that a hæmorrhage should occur from any part of the surface of the body, as the result of a wound or abrasion, and let us follow out the principles which one after another would be employed by the surgeon, until he finally succeeds in checking it.

1st. If the flow were slight the patient would be kept perfectly quiet, and an effort made to constrict the mouths of the bleeding vessels by cold and styptic applications, as ice, alum, tannin, matico, etc.

2d. Should these very useful and commonly employed hæmostatic agents fail in making this principle effective, an attempt might be made to cause in the wound the formation of a coagulum, which, extending up into the mouths of the bleeding vessels, might seal them up as is done by plugging the anterior nares (alone or with the posterior), in epistaxis.

3d. Should this fail, a very excellent principle, that of closing the open arterioles by firmly compressing their walls, might be developed by direct pressure, as is done, for instance, in hæmorrhage from the palmar arch, by placing a billiard ball in the palm of the hand, and binding it firmly in its place by a bandage.

4th. Should even this fail, still another and surer one exists in the application of a ligature to the bleeding vessels; and to it the surgeon would now with confidence resort.

Thus, one after another, he has brought to his assistance four principles, each valuable in itself, each differing from the one tried before it, and all capped by one which is as certain in its results as human means can ever be.

Thus, too, in parturient hæmorrhage the obstetrician should act; and he will find that, if the first three of these four principles fail him, he, like the surgeon, will have one left which will prove as certain as the ligature.

In establishing these principles, always be mindful of the pathological state which causes the dangerous symptoms which they are to control; *i.e.* that a portion of the placenta has been torn off from its uterine attachment, and that from its disrupted face, as well as from the corresponding surface of the uterus from which it was torn, the blood is welling forth.

In a case of accidental parturient hæmorrhage, the first indication to be fulfilled is to check the flow by constricting the mouths of the vessels; and this will best be accomplished by confining the patient to bed in the supine posture, and absolutely prohibiting all muscular effort or mental exercise, even that attendant upon speaking; by keeping the apartment cool; by administering cold, acidulated drinks, as lemonade, or water acidulated with the elixir of vitriol; by applying towels soaked with cold water, or vinegar and water, to the vulva and over the uterus, and by prescribing astringents, as tannic or gallic acid in full dose, which being

carried to the bleeding vessels by the circulation, may aid in producing the same result which their local application effects in vascular rupture elsewhere.

If by these means we succeed, we will have good cause for congratulation, for we will have relieved the woman without having in any way sacrificed the chances of her child. If they do not succeed, then we must resort to some other plan which may prove more effectual, and we enter into the consideration of the adoption of the second principle. The only available means at our command for causing a clot to form in utero, under these circumstances, is the tampon or vaginal plug; an agent advised by many, and one which might accomplish the result as perfectly as do the double tampons employed in epistaxis. But there are dangers attending its use, so great, that I must not only guard you against them, but advise an avoidance of this means in parturient hæmorrhage, except in rare and particular cases. I would say in advance, avoid the tampon as a rule, after the seventh month of pregnancy, but employ it boldly, even at full term, in a few exceptional and peculiar cases.

The tampon may be styled one of the most useful and dangerous of our uterine hæmostatics, and it is really curious to see how different and even contradictory is the advice which is given concerning the propriety of its employment. Let me, by an excusable digression, endeavor to fix in your minds this morning a few maxims concerning it.

A plug introduced into the vagina, of sufficient size to fill the canal, acts in uterine hæmorrhage in one of two ways. 1st. Preventing the escape of the fluid which is flowing out of the uterus, this collects, and gradually accumulates in the cavity above. Soon it distends this cavity to its utmost extent; if the fœtal mass is present, insinuates itself between its envelopes and the uterine wall, and at last forcibly dilating the os by distension of the whole organ, produces a powerful expulsive effort which frequently expels child, accumulated blood, and tampon together. 2d. When the uterus is not dilatable by the accumulating blood, this fluid coagulates within its cavity; and the coagulum, beginning to form at the os, and extending upwards towards the source of the hæmorrhage, will often seal up the mouths of the bleeding vessels.

The latter of these results is often very desirable, and to accomplish it no means compares with the tampon. But after the seventh month of pregnancy the uterus is so large that it may contain a sufficient amount of blood to produce death, so that from this period to the completion of labor it is always attended by danger. (I need not insist upon the gross impropriety of the employment of such a means after delivery.)

Thus, then, although the tampon might effect much for us in puerperal hæmorrhage, as a rule it should not be employed; and, in exceptional cases which demand it, should be resorted to only after mature consideration, and its effects be watched with very careful scrutiny. Observe these rules in using it:

Never employ the tampon from choice when there is a possibility of a dangerous internal hæmorrhage.

At full term do not employ it after the waters have been discharged, for then the uterus will accommodate a large amount of blood.

Never employ it at full term after your patient has lost a great deal of blood, or from natural feebleness of body would be endangered by even a slight hæmorrhage.

In a strong woman who has not already lost a good deal of blood, in whom the uterus is contracting well, and whose bag of waters has not been ruptured, I would not hesitate to employ it if other means failed, or from any reason I deemed them inapplicable.

Should the principle which is developed by the tampon be beyond our reach on account of the danger of the means which accomplishes it, or, should it have been unsuccessfully resorted to, how are we to avail ourselves of the third?

You remember that the flow of blood in accidental parturient hæmorrhage is checked by uterine contraction, and that this is so marked as to constitute one of its characteristic symptoms; now let us examine this fact. When the organ contracts, the bleeding surfaces of the placenta and uterus are pressed firmly against the fœtal mass, and thus their open vessels are shut. If we could cause this pressure to be continuous and powerful, at the same time that it was resisted by a hard mass, we would cause the flow to cease entirely, and would be acting exactly as the surgeon does who binds the billiard ball in the palm of the hand. But you may ask how are we to introduce a hard resisting body into the uterus to act as counterpart of the ivory ball? We are supplied with such a substance in the body of the child. Surrounded by the soft and pliable bag of waters, one chief object of which is to prevent its hardness from being perceived by the sensitive uterus, it lacks the feature of resistance which we now desire; but evacuate the surrounding waters by puncturing the bag, and instantly the unyielding body presses against the hæmorrhagic spot, and the principle is developed.

This, however, although often sufficient, is not always so—the pressure not being powerful enough. Under such circumstances, in the case of a palmar hæmorrhage, the surgeon would remove his loose bandage, and apply another which would make all the pressure desirable. And so the obstetrician, by the administration of small doses of ergot, can so force his point of resistance against the bleeding surface as to compress entirely the ruptured vessels and render them impermeable. By these means you not only bring to your aid the principle mentioned, but, to a certain extent, you will establish that which will be mentioned fourth, for the vessels are diminished by the same contractions which press the child against the bleeding surface. According to my experience it is rare for them to fail. In fact, I have never known them do so in true accidental hæmorrhage. Should they do so, however, but one resort remains, and that is ligation of the vessels from which the obstinate current flows. Have we any means by which ligatures may be thus applied in utero? Again bountiful nature comes to our aid, and we have but to use the means which she presents us and our end is accomplished. After every natural labor, were there not some arrangement for checking the flow from the broken utero-placental vessels, a hæmorrhage would occur, but so soon as the uterus is emptied the fibres contract, diminish its size very greatly, and being arranged around the mouths of the vessels as the meshes of a netted pursé are around the finger which is pushed through them, they inevitably close their mouths, and prevent all sanguineous loss.

After having tried in vain, by the development of the three principles mentioned, to accomplish what we wish, naught remains but to empty the uterus, force it into contraction, and cause nature to do what the surgeon does in external hæmorrhage. If the head can be seized by the forceps, employ them; should it be out of their reach, accept of version as the alternative, and deliver promptly. Thus by successive steps the scientific obstetrician advances from mild, harmless, but correspondingly inefficient means, to more dangerous, and proportionally more effectual ones, until he arrives at a point at which he can safely say, "I will by this surely

succeed in staying the flow, and will rescue my patient from its dangers."

But do not despise the more inefficient means because a more effectual one exists. Would you not blame the surgeon, who, for a slight hæmorrhage, should tie the supplying arteries without seeing what might be done by styptics, pressure, etc.?

Keep the most efficient agent in reserve, because it is accompanied by danger for mother and child, and always strive to accomplish your ends by the mildest, least dangerous, and apparently most trifling means. Should you succeed, a host of unthought-of evils lurking like harpies in the shade, may by your moderation be avoided; should you not, then promptly apply the most efficient and most dangerous of your resources, which, like a "corps de reserve," you have kept until the fitting moment.

What has been denominated "heroic practice," often marks the course of the ignorant and unreflecting obstetrician; and although the vulgar may be blinded by its show of energy, decision, and promptness, and led to believe it an evidence of knowledge, it will often bring about consequences alike disastrous and avoidable.

Never lose sight, too, of this fact in treating a complication of labor, that the interests of two beings are intrusted to your care, and that while you are to do all in your power for those of the mother, those of the child are scarcely less imperative. If, then, in the treatment of this accident, you can adopt means which will accomplish both ends, give them by all means the preference over those which, even if more surely effectual in removing the woman from danger, will sacrifice the chances of the child.

The older one grows in obstetric experience, the more convinced does he become that many a woman has died from the unnecessary introduction of the hand into the uterus; that many a uterus has been ruptured by uncalled for violence; and that Herod destroyed not a tithe of the children which have been killed in utero by the reckless use of ergot.

The following is a résumé of the treatment which has been recommended in this lecture, the principle upon which each procedure acts being italicised.

1st. *Constrict the bleeding vessels* by cold to the uterus and vulva, acidulated drinks, astringents, and perfect rest in the recumbent posture.

2d. In case of failure *cause a clot to form in the mouths of the bleeding vessels* by the tampon, should the case be one in which this practice would be safe.

3d. Should this fail, *make direct pressure against the bleeding vessels* by evacuation of the waters, and increase it if necessary by the use of ergot.

4th. None of these means succeeding, *ligate the vessels* by evacuating the uterus, and causing firm contraction.

The last of these means it will rarely be found necessary to resort to in the variety of hæmorrhage which we are considering; for few cases will resist evacuation of the liquor amnii. There are many cases, however, in which it will be desirable not to lose this protective fluid, and in these the two first methods may subserve our purpose.

PHARAOH'S SERPENTS.—Dr. Littlejohn, of Edinburgh, warns the public against the use of "Pharaoh's serpents," as they are called. These toys are a compound of sulphocyanide of mercury. The inhalation of some of these products is highly dangerous; viz. cyanogen, sulphurous and sulphuric acids, bisulphide of Carbon and mercury in vapor. The mass left after combustion is organic matter called "mellor."—*British Medical Journal.*

THE MEDICAL RECORD.

A Semi-Monthly Journal of Medicine and Surgery.

GEORGE F. SHRADY, M.D., EDITOR.

Published on the 1st and 15th of each Month, by
WILLIAM WOOD & CO., 61 WALKER STREET, NEW YORK.

EUROPEAN AGENCIES.

LONDON—STEVENS BROS. | LEIPSIC—B. HERMANN.
PARIS—BOSSANGE ET CIE. | RIO JANEIRO—STEPHENS Y CA.

New York, March 1, 1866.

PROSPECTUS.

IN presenting to the medical profession throughout the country the first number of the MEDICAL RECORD, we deem it incumbent upon us to offer a statement of the general plan upon which this journal is to be conducted.

Its object will be to present to the profession a faithful record of the existing state of medical science in every one of its many departments; and as it is more especially intended to meet the wants of the general practitioner, all the different articles published in its columns will be thoroughly practical in their character. With a wide field, and ample facilities for working it up, we earnestly hope to fulfil to the letter this part of our design, thus making the RECORD worthy of the countenance and support of the profession; a journal to which they may at all times look for information, instruction, and edification.

A word with reference to its contents: For the Original and Lecture departments we have been promised contributions from some of the most noted writers and teachers in the profession, the names of some of whom we have the pleasure of announcing in another place.

The abundant material which is constantly accumulating in our large hospitals, in this and other cities, will be from time to time presented to our readers in the shape of accurate reports of interesting cases; at the same time every care will be taken to keep them well informed of all those various improvements and modifications in the treatment of disease which are so frequently made in those great schools for practice and observation.

A carefully prepared abstract of the *progress of medical science* will appear in each number, as well as accurate and trustworthy reports of the proceedings of the different learned bodies. Believing, too, that we shall meet a want long felt, especially among gentlemen who are distant from our large cities, for a notice of *improvements* in *instruments*, we have undertaken to set apart a given space in our columns for that purpose. The Review department will receive our special attention, and all works sent us will be promptly and im-

partially noticed. The news of the day will be given as completely as our means for receiving information from the different medical centres will allow; and in managing this department, no opportunity will be lost for affording full reports upon all matters which are of general interest to the readers of a medical journal. The Lectures, from prominent Professors in the different colleges, will be accurately presented to our readers, as special pains will be taken to have the manuscript reports of the same carefully revised by the speakers themselves before they are submitted for publication.

The current medical topics of the day will be freely and independently discussed; and no effort on our part will be spared to render ourselves well informed with reference to them, in order that we may be able to present such views to the profession as a body, as shall be considered worthy of serious attention on their part. In all this, our simple aim shall be after truth; and in our efforts to expound the great principles upon which our relations to each other and to the community are to be based, we shall look to the Code of Ethics adopted by the American Medical Association as the grand standard by which all our assertions must be measured. Impartial to all, unjust to none, it is our purpose, so far as we are able to understand the right, not to hesitate, on the one hand, to point out the way which, by the correction of certain abuses, may lead to a still higher development of professional excellence; nor to be backward in upholding the claims and discussing the merits of the various vexed questions which are ever arising to claim our attention. Committed to the interests of the profession as a whole, it shall be our constant endeavor to keep the columns of the RECORD free from any element that may savor of cliqueism or party spirit; and in the discussion of all subjects, great and small, to exercise that spirit of charity and honesty which must always attach itself to the side of truth, and commend itself to the sanction of every independent thinker.

Believing that a plan thus generally carried out will meet the requirements of a standard medical journal, we submit it as such to the profession for their approval, earnestly soliciting from them any additional suggestions which might tend to increase its usefulness.

THE coming meeting of the State Medical Society, to be held at Albany, will no doubt be largely attended, and the session, from what we can learn, promises to be as interesting and profitable to all concerned as any of the previous ones. This society has, by the united action of its members, already gained for itself a reputation for usefulness which is second to none other of its kind; and by the continued efforts which are now being made in its behalf by the representative men from the different counties of the State, it bids fair to increase still more its enviable reputation. The attendance of the members and delegates has been of late years markedly on the increase; and many who in times past were content to stay at home and allow others to take part in the deliberations of the body, are now to be numbered among its most earnest workers. We sincerely hope that this interest will so continue to develop itself, that more of the prominent physicians from our large cities may be induced to be present. The *Transactions* of this body have, perhaps, a wider circulation, not only among the general profession, but among non-professionals as well, than any other similar publication. This insures for every author of a paper a large number of readers, and should of itself stimulate more of our medical writers to contribute to its pages. The different volumes of the *Transactions* that have been issued for years past, while they have tended to reflect credit upon the body from which they emanate, are nevertheless susceptible of vast improvement in reference to the character of many of the papers which have appeared in them. We sincerely hope that this improvement will be made in the volume which shall represent the doings of the body during the coming meeting, and that every care will be taken to exclude all articles which do not come up to the required standard. If this be done, more will be stimulated to contribute to the enrichment of its pages, and in the end all will be more substantially benefited.

WE would not be doing justice to a very important movement which has lately been made in this city for the benefit of the profession, if we did not take the first opportunity offered us of giving some account of its history. We refer to the New York Medical Journal Association. About a year ago, a number of the prominent medical gentlemen of New York assembled at the house of Dr. ISAAC E. TAYLOR to discuss the propriety of establishing a "journal club" on a large scale. After numerous meetings and lengthy discussions, the Association was formed, and by liberal contributions on the part of the substantial members, a reading-room was established, and the various journals—English, French, and German—subscribed for. It has now been in existence for more than a year, and for the success which has attended the effort, too much praise cannot be given to those few who, by their exertions, have succeeded in placing it where it now is. We understand that thus far, financially, it is safe; and from the favorable indications which are constantly becoming manifest, and from the very encouraging endorsement which it is receiving from the profession of this city, that there is before it a prosperous future.

A very pleasant feature connected with the doings of this Association, has been the occasional "Re-union" of its members. At these times invited guests are also present, and there is every opportunity and inducement offered for the freest social intercourse. The busy practitioner for a while forgets his patient, and the surgeon is content for the time to think of something

else than his last operation; and all, with one accord, seem bent upon entertaining each other. The younger practitioner is taken by the hand and made to feel at home among his fathers; and an opportunity is thus afforded him of cultivating the acquaintance of men whose opinions he has learned to respect, and whose examples he is anxious to follow. These entertainments are rendered still more pleasant and profitable by the occasional presentation of subjects of interest by gentlemen who kindly volunteer their services for the occasion. At the last "Re-union," held January 25th, some very interesting remarks were made by Dr. RUFUS KING BROWNE, on the application of the microscope to medicine, following whom, Dr. NOYES entertained all present with the history of the binocular ophthalmoscope, and took occasion, in connexion with it, to refer to some very curious phenomena associated with binocular vision. The entertainment closed with a suitable collation, and every one went away satisfied with what he had seen and heard. The profession in this city need just such an Association, and they should not allow it, for want of the proper support and encouragement, to die out. We wish it that success which it really deserves, and which we have no doubt it will attain.

THE establishment of ophthalmic and aural clinics during the past winter in connexion with our different medical colleges in this city, may be regarded as a very important step in the right direction in affording the student of medicine increased opportunities for becoming acquainted with this most important class of diseases. In the COLLEGE OF PHYSICIANS AND SURGEONS this department has been taken charge of by DR. C. R. AGNEW, in the UNIVERSITY MEDICAL COLLEGE by DRS J. H. HINTON and D. B. ST. JOHN ROOSA, and in the BELLEVUE MEDICAL COLLEGE by DR. H. D. NOYES. These, we understand, are all in successful operation, and bid fair to become permanent features in our college courses. We hope this example will be followed by the other medical institutions throughout the country.

NEW medical journals are showing themselves from all sections of the country, and medical journalism is beginning to receive an amount of attention which it has for a long time needed. With the commencement of the year the following periodicals have made their appearance: The RICHMOND MEDICAL JOURNAL, edited by Drs. E. S. Gaillard and W. S. McChesney; the GALVESTON MEDICAL JOURNAL, edited by Dr. Greensville Dowell; and the CINCINNATI JOURNAL OF MEDICINE, edited by Drs. G. C. Blackman, Theophilus Parvin, and Roberts Bartholow.

IN order to correct any seeming anachronism, we would state that this number is issued one month in advance of its date.

Reviews.

THE PRINCIPLES OF SURGERY, by JAMES SYME, F.R.S.E., Surgeon in Ordinary to the Queen, in Scotland; Professor of Clinical Surgery in the University of Edinburgh, etc., etc. To which are appended his treatises on the "Diseases of the Rectum," "Stricture of the Urethra and Fistula in Perineo," "The Excision of Diseased Joints," and numerous additional contributions to the pathology and practice of surgery. Edited by his former pupil, DONALD MACLEAN, M.D., L.R.C.S.E., Professor of the Institutes of Medicine, and Lecturer on Clinical Surgery, Queen's University, Canada. Philadelphia: J. B. Lippincott & Co., 1866. 8vo. pp. 880.

THE work before us is a condensation of the author's lectures on the principles of surgery, and as such it commends itself to every student of that department who is desirous of becoming acquainted with the views of a master. It aims only at giving a substantial outline of the science, leaving the reader to fill up the gaps by his subsequent studies. This is professedly the object of the author, and one in which he has succeeded. The character of the work, as a whole, is, in spite of the old-fashioned views of the author, which here and there crop out, eminently practical. The style of the work is very concise, elegant, and forcible, and really forms one of its most attractive features. The appendix, containing the scattered writings of the author, and collected by the editor, considering the valuable amount of interesting and useful information contained in it on the different important surgical questions, is of itself worth the cost of the whole volume. Embodied in this portion, which occupies a space of over three hundred pages, we have a practical and valuable monograph on "Diseases of the Rectum;" one on "Stricture of the Urethra;" besides a general collection of miscellaneous cases. The chapter on amputations is one of great interest and practical value; and not the least important of its features is a full and complete description of the author's method of removal of the foot at the ankle-joint. This operation, since it was first devised by the author, has been very successfully and extensively practised on both sides of the Atlantic; and notwithstanding the attempts at improvement upon it which have been made, it is at the present day the one most in favor with all the leading operators. The author's operation for impermeable stricture by external incision, detailed in the appendix, is also one which has met with great favor, and, by its frequent and successful performance, has given to Professor Syme almost as much reputation as has for a long time attached itself to his method of ankle-joint amputations.

The work is elegantly got up by the publishers, printed in clear type, on good tinted paper, with several first-class wood cuts.

THE PRACTICE OF MEDICINE, by THOMAS HAWKES TANNER, M.D., F.L.S., Member of the Royal College of Physicians, Vice-President of the Obstetrical Society of London, etc., etc. From the fifth London edition, enlarged and improved. Philadelphia: Lindsay & Blakiston, 1866. 8vo. pp. 835.

THIS work is virtually an enlargement of the author's manual, which has been so long and favorably known to the profession. A large amount of valuable and interesting matter has been added, which, although it swells the volume to one of large size, makes it a more complete work. Considering the great variety of subjects discussed, it cannot be expected that each should receive that amount of attention and space which it should justly claim in a more comprehensive treatise on the practice of medicine.

It is very conveniently arranged, and fulfils its intention to the letter, in giving to the student and practitioner a work in which he can obtain, in the smallest possible space, all the important practical information with reference to any particular disease. Although it can hardly be called a manual, it still possesses all the attractions of such a work, while at the same time it claims for itself most of those advantages which properly belong to an exhaustive treatise. There is hardly a disease in the whole domain of practical medicine which does not receive its share of attention, and the student can always go to the work with an assurance of finding what he wants. We need hardly say that the publishers have exercised their usual good taste in getting up this work.

Clinical Lectures on the Principles and Practice of Medicine, by John Hughes Bennett, M.D., F.R.S.E., Professor of Institutes of Medicine, and Senior Professor of Clinical Medicine in the University of Edinburgh, etc., etc. Third edition, with five hundred and thirty-seven illustrations on wood. New York: William Wood and Company, 61 Walker st., 1866. 8vo. pp. 1004.

The previous edition of this work on the practice of medicine has been received everywhere with favor, and has given Professor Bennett a reputation as a teacher and writer which is second to that of no physician in the world. He has the enviable faculty of blending together so perfectly the theory and practice of our profession, that one is almost at a loss to know where to draw a dividing line. Convinced, by his long and varied experience, of the wants of the medical man, he has successfully striven to give a complete treatise on the practice of medicine, and does not hesitate to assert boldly his views upon the different vexed questions which are so constantly arising. His remarks under the head of General Therapeutics, which are some of the many important additions to the last edition, stamp him not only as an acute observer, but as one who, in the earnest search after truth, desires to picture to the mind of his readers, not only all that has actually been done in the progress of the healing art, but what remains to be done. Every new improvement receives its share of attention, and his teachings with reference to the true applications of the microscope, the stethoscope, and the laryngoscope to practice, are of themselves of sufficient value to induce every one to become the possessor of the work.

The new edition has added to it about three hundred pages, many subjects being entirely new, while others have been for the most re-written. Every section has been thoroughly worked up, and every recent improvement in practice has been freely and fully discussed, which altogether stamps the work as one which is a truthful exposé of the present status of our science. In spite of the many additions, this edition is not increased in bulk compared with the last, as there have been many curtailments and condensations made, and closer type employed; the only difference being a slight enlargement of the page. We commend this new edition to every one who is anxious to possess a complete treatise. The execution of the work is fully equal to that of any of the former editions.

The Preparation and Mounting of Microscopic Objects, by Thomas Davies. New York: William Wood & Co., 61 Walker street. 12mo. pp. 143.

This little work combines, in a very attractive form, an account of all the approved methods of collecting and mounting microscopic objects. It is divided into seven chapters. The first chapter treats of the "Apparatus;" the second gives full and practical directions or mounting objects dry; the third for mounting in Canada balsam; the fourth gives an account of preservative fluids; the fifth details directions for making sections and dissections; the sixth describes the different kinds of injections to be used; and the seventh closes up the work by a reference to miscellaneous matters. It is a manual that is designed more particularly for the amateur microscopist; as a consequence, the methods of preparation of objects interesting to a physician are only incidentally alluded to. Those who are interested in microscopy outside of its application to medicine, will find this a useful and valuable work.

Chloroform, its Action and Administration, by Arthur Ernest Sanson, M.B., London, late House Physician and Physician-Accoucheur Assistant to King's College Hospital. Philadelphia: Lindsay & Blakiston, 1866. 12mo., pp. 274.

We have read this book with a great deal of interest and satisfaction, and feel assured that it is the most comprehensive and practical of any that has heretofore treated of this all-absorbing topic. The author, after giving an interesting history of the discovery of chloroform, proceeds to treat of the different effects produced by its inhalation, the dangers attending its use, the precautions to be taken in its administration, the most approved methods for resuscitation in cases of accident; and closes the volume by occupying the four last of the twenty chapters composing the work, in the consideration of the practical application of anæsthesia to surgery, obstetrics, practical medicine, and dentistry. Every part of the work is thoroughly practical, and clearly proves to the reader that the author understands perfectly what he is talking about. The profession has long been in want of just such a work. We cannot commend it too highly.

Reports of Hospitals.

NEW YORK HOSPITAL.

THREE CASES OF POPLITEAL ANEURISM SUCCESSFULLY OPERATED UPON BY LIGATION.

Reported by Thomas T. Sabine, M.D., Resident Surgeon.

I. Popliteal Aneurism—Unsuccessful Employment of "Flexion."—Subsequent Ligature of Femoral.—(Service of Dr. Gurdon Buck.)—Richard J. Curl, aged 27, cook, colored; was admitted to the hospital, May 2d, 1865, with an aneurism of right popliteal, of which he gave the following history:

About a year before admission, he noticed in right ham a small pulsating tumor about the size of a hickory-nut; his attention being called to its existence by the pulsation felt in crossing one leg over another. He could assign no cause for its origin. There was no pain or increase in the size of the tumor until four weeks before admission; when, without any known cause, it began to increase somewhat rapidly, with pain and swelling, seated chiefly in the calf of the leg. The pain and swelling have since greatly diminished. On examination there was found a pulsating tumor, the size of a hen's egg, occupying exactly the middle of right popliteal region. Auscultation revealed a distinct bruit. There was some enlargement of the superficial veins of the affected leg, but no œdema. An aortic systolic murmur could be heard.

On May 11th, the leg was flexed upon thigh to an angle sufficient to cause all pulsation in tumor to cease, and retained in that position. On May 25th, the above

treatment was discontinued; the extreme pain and constitutional irritation induced, notwithstanding the free exhibition of opium, having prevented its continuous application.

On June 1st, the femoral was ligated by Dr. Buck in the usual manner and situation, and the limb subsequently enveloped in cotton batting.

On June 8th, the tumor was about one-half its original size, and firm. The temperature of the limbs had remained equal. There had been some pain and slight constitutional disturbance, which soon subsided.

On June 26th, the ligature came away, and on the 29th the wound had closed.

II. Popliteal Aneurism—Unsuccessful Employment of Flexion—Subsequent Ligation of Popliteal—Recovery.—(Service of Dr. Thomas M. Markoe.)—Reuben Harris, aged 62, waiter, colored; was admitted to the hospital on July 3d, 1865, with an aneurism of left popliteal, of which he gave the following history:

On April 4th, 1854, the left femoral was ligated by Dr. Maxwell, of this city, for a popliteal aneurism. The tumor entirely disappeared, and patient returned to his employment. He had no further trouble until the July riots in 1863, when he was maltreated, being beaten about the left leg, etc., since which time he has been unable to use the limb perfectly, walking with a limping gait.

In the beginning of November, 1864, he began to experience pain at the site of former disease in going up or down stairs. This increased to such a degree that about the middle of the following month he was obliged to give up his employment. At about this time he noticed a small tumor, in the left popliteal region, which had steadily increased in size up to the time of admission.

An examination showed the existence of a pulsating tumor the size of the fist, traversing the inner aspect of which, an artery of considerable size could be felt. Auscultation revealed a distinct souffle, which, it was thought, pressure on the popliteal below the tumor rendered less clear. The same pressure seemed to diminish the pulsation. There was a distinct diastolic aortic murmur. Pulse irregular.

No special treatment was adopted until July 20th, when the tumor, meanwhile, having undergone no increase in size, it was decided to treat it by flexion, as all pulsation and sound ceased in tumor when the leg was brought to about a right angle. This plan was pursued until August 7th, with no beneficial result, when it was considered best to ligate the nutrient artery.

The requisite incisions having been made, Dr. Markoe found that the aneurism had been developed from the anterior aspect of the artery, which had been pressed backwards so as to run over the posterior surface of the tumor. A ligature was applied a short distance from the sac, when all pulsation and souffle instantly ceased. The limb was then ordered to be kept somewhat flexed, and lying upon its outer side.

On August 30th, the ligature came away. The limb had maintained its temperature well, and no pain had been experienced since the operation. On October 5th, the resulting ulcer had quite closed, and patient could flex and extend the leg almost as well as before the appearance of the tumor, which, very much diminished in size, could be felt consolidated and pulseless.

III. Popliteal Aneurism—Ligature of Femoral.—(Service of Dr Gurdon Buck.)—John Smith (colored), 27, hotel porter; a strong healthy mulatto, was admitted to the hospital, Jan. 4th, 1866, suffering from an aneurism of left popliteal, of which he gave the following history: About a month before admission, while jumping from the hotel coach to the ground, he experienced a feeling as if something had given way in the left popliteal region, accompanied with a "cramp," which soon subsided, giving place to a dull, aching pain, which increased but little up to a few days before admission, when it became much more intense. At the time of this increase he first noticed the tumor.

An examination in both the upright and recumbent posture detected a slight fulness, hardly perceptible, in the left popliteal region.

On handling the part, however, a tumor the size of a turkey's egg, and occupying the lowest portion of the space, could be felt pulsating with a slow, heaving, expansile movement, lifting and separating in a very characteristic manner the fingers, placed at different points. The diastolic impulse, mentioned by Gendrin as sometimes occurring, could not be perceived. Auscultation revealed a murmur resembling very perfectly the puffing of a distant steam engine. Pressure applied to the iliofemoral artery caused the tumor to subside, and at the same time the pain in the limb to cease. There was œdema, not very marked however, about the limb below the knee, which was noticed about the same time as the tumor. The pain, which was considerable, and on the increase, was referred principally to the ramifications of the internal popliteal nerve. Heart-sounds were natural. Pulse was regular and slow—about sixty-four.

On January 9th, the tumor had not increased perceptibly, though the pain was more severe and continuous, and the œdema had become rather more marked. Limb had been kept moderately flexed, as being the most easy position. Complete extension greatly increased the pain; and flexion to such a degree as to exercise any effect upon the tumor, though kept up only a few moments, was found to be unendurable.

A ligature was applied to the femoral at the usual point, by Dr. Buck. Pulsation in tumor instantly ceased. Limb enveloped in cotton batting and kept somewhat flexed on outside.

January 17th; there has been no constitutional disturbance whatever. Wound closing well. Ligature still *in situ*. Cotton was kept on only for first day or so, the limb having throughout maintained its temperature well; the thermometer at no time or point indicated more than one-half degree difference. The tumor has diminished to at least one-half its original size, and is quite firm. The œdema of limb disappeared soon after the operation, and the relief from pain has been complete. No pulsation as yet in the posterior fibial.

The above cases, occurring within a period of nine months, are interesting in their bearing upon the subject of the treatment of aneurisms occurring in the neighborhood of joints by position.

In the two first it was fairly tried and failed; and in the third it was evidently altogether inapplicable.

BROOKLYN CITY HOSPITAL, N. Y

I.—GUNSHOT FRACTURE OF SKULL—DEATH. II.—GUNSHOT WOUND OF CHEST—RECOVERY.

Reported by Charles Fox, M.D., House Surgeon.

Case I. Gunshot Fracture of Skull.—Death.—(Service of Dr. De Witt C. Enos)—W. H. Russ was brought to the hospital on the 23d of December, after attempting to take the life of his *protégé* and to commit suicide. He was a slightly-built, delicate-looking man of 32; a clerk by profession, residing in New York. After firing three barrels of his revolver at the young lady, he discharged the two remaining shots into his own head, aiming at the right eye. Finding that he was not even stunned by the shots, he rushed to the

foot of Atlantic street and leaped into the East river; not noticing in his haste, that the tide was out, and that there was not above a foot of water in the slip. He then climbed from his unpleasant situation without assistance, and was soon afterwards arrested by the police, wandering about the streets with no apparent purpose. When brought to the hospital, about two hours afterwards, he was much chilled from the effects of the water, but soon recovered his natural temperature on being covered up with blankets and well rubbed. One ball had entered just outside of the superciliary ridge on the right side, and the second half an inch below the corner of the eye, which was pushed forward and distended. The hæmorrhage, after admission, was very slight; but his clothing was saturated with blood. His demeanor was singularly calm;—he said nothing voluntarily, but answered questions readily.

The following morning Dr. Enos enlarged the wounds and removed some loose pieces of bone, and the upper ball. After the operation, the finger could be readily introduced into the orbit through the opening in the frontal bone. A few small arteries were tied, the edges of the wounds brought together by sutures and adhesive strips, and a water-dressing applied.

The condition of the patient remained much the same until the 30th. The pulse, skin, and tongue were normal. He slept comfortably with an anodyne, and felt hardly any pain, except a soreness of the neck and back. The wounds looked well, and the pus from them was healthy. He refused all food except a few spoonfuls of tea a-day. On the 30th, he became slightly delirious, and had a determination of blood to the head —three arteries in the wound began to bleed, but were secured before any damage was done. The next day, the discharge from the wounds became offensive, and a low delirium set in. He continued to answer questions intelligently, but muttered to himself constantly. The tongue was protruded slowly and with great difficulty; the surface was covered with perspiration; the pulse averaged about 110, and was very weak; and the pupil of the uninjured eye was contracted. When touched, he screamed from pain in the back and neck. He no longer refused food, but swallowed with avidity everything given him These symptoms were soon followed by subsultus tendinum, and he died at 3 A.M. on the 3d of January.

The *autopsy*, thirty-three hours after death, showed that the upper ball had broken out a piece of the frontal bone, as diagnosed. The lower ball had chipped out a piece of the malar bone in passing, and struck the roof of the orbit just above the optic foramen, whence it glanced down and comminuted the inner wall of the orbit, imbedding itself in the superior maxillary. At the point where the roof was struck, a fracture was produced, and a fragment of bone was found pressing upon the dura mater, which was separated from the bone by a small clot. At the point of injury there seemed to be no lesion of the brain; all its substance being firm and white, except in one spot near the right ventricle, where it was somewhat disorganized. The membranes were very much congested, and pus was found filling the ventricles and spinal foramen. The cerebellum was thickly covered with coagulable lymph, closely adherent, and a few shreds were found over the hemispheres. In the anterior maxilla was a small clot.

II. Gunshot Wound of Chest—Hæmoptysis—Recovery. —(Service of Dr. De Witt C. Enos.)—J. R. G., aged 22, was brought to the hospital, December 9th, 1865, with a pistol-shot wound in the left breast, inflicted by himself. The ball had entered between the fourth and fifth ribs, an inch inside of the nipple, and emerged between the same ribs through the latissimus dorsi and teres major muscles, passing through the lung. Immediately after the receipt of the injury he raised bright-red blood, though not enough to cause any apprehension. He felt little or no pain, and though he coughed frequently, did not seem to be suffering from it. The wounds were covered with greased lint, and the patient was kept as quiet as possible.

For two days he had a slight traumatic fever, which disappeared on the third, from which time his improvement was rapid. He continued to raise blood in small quantities until the 16th, when the hæmoptysis ceased, though the cough continued a day or two longer. The chest was carefully explored daily, and no abnormal signs were at any time detected. On the 19th he considered himself well enough to leave the hospital; and as the cough had entirely ceased, the wound of exit had closed, and the wound of entrance was filling up well, he was discharged. On the 2d of January he called at the hospital and reported that he was still improving, and had had no bad symptoms.

MEDICAL CASES FROM SAME HOSPITAL.

Case I.—Cancrum Oris—Recovery. Case II.—Softening of Brain from Thrombus—Hemiplegia—Death.

Reported by Francis H. Atkins, M.D., House Physician.

Case I. Cancrum Oris—Recovery.—(James Crane, M.D., Attending Physician.)—George K., aged 6, native of U. S., German parents. Admitted Nov. 3, 1865. History from parents. Was taken four weeks before with typhoid fever. After two weeks, when the disease was abating, a dark spot appeared on the inside of the right cheek. Notwithstanding the remedies applied, the spot increased rapidly in size until a large portion of the cheek became sphacelated. There was no knowledge of the administration of mercury. The child had always been very healthy. On entering the hospital, the whole thickness of the cheek, including mucous membrane and integument, was found destroyed over an area measuring one and seven-eighth inches vertically, and two and one-fourth from before backwards. The slough, which had not yet separated, was black, and evolved an extremely disagreeable odor.

The angle of the mouth and a portion of the lower lip were involved. The gums appeared sound. The adjacent tissues of the cheek were indurated and much thickened. There was no pain. There was much emaciation and physical weakness. The skin was very anæmic. Breath foul. The little patient's appetite was excellent. Pulse 144, rather weak.

Treatment.—A yeast-poultice was applied, and the cheek was washed with Liq. sodæ chlor. Application was made at once of concentrated hydrochloric acid to the edges of the opening, to prevent the further spread of the gangrene.

As the mouth could be opened but a little way, it was almost impossible to apply the acid to the inner side of the cheek without touching the gums. Ferri pyrophos. gr. iv.; Tr. cinch c. ʒj.; and Potassæ chlor. gr. v., was ordered four times a day. Wine ʒiv to ʒvij. daily. Plenty of beef-tea, milk, etc., and meat as soon as it could be masticated. The fetor was relieved at once. On the 6th nearly the whole of the slough had separated, exposing the teeth and tongue.

The next day all the slough was removed from the cheek, leaving a clean, granulating surface; but along the lips the gangrene was still extending.

Nov. 10th.—The opening measured two inches by two and one quarter. 11th.—Septum and alæ nasi attacked. 13th.—Cheeked on lower lip. Still slowly advancing

on upper lip. Pulse 120, weak. General condition good. 15th.—Checked on upper lip. Removed the last slough. 16th.—A clean granulating surface now remained on lips and cheek, measuring two and a half by two inches; the gangrene having extended, since entering, almost only in the direction of the lips. More than half of each lip was destroyed. The septum and alæ nasi had been affected for about one-eighth of an inch.

The strong hydrochloric acid was applied daily until the 15th, and to the action of the acid is chiefly attributed the checking of the gangrene. Had it been applied even more freely than it was, perhaps the sphacelus might have been arrested much sooner.

The child's appetite and digestion remained remarkably good throughout.

On the 20th he was so much improved that he was removed to his home, where he was afterwards seen by the reporter. The tonic treatment was continued. Dec. 2d.—General health excellent. Gained much in flesh and strength. Running about, playing; ulcer looking well; had contracted; measured two inches by one and two-fifths. Several teeth loose. Some necrosis and suppuration in alveolar processes; deeper in the superior maxilla, from which a piece of bone three-quarters of an inch long was removed. This was probably caused by the acid. 23d.—Ulcer one inch by one and a half. The molar teeth above and below had come away. Suppuration still in the superficial portions of the bones. 31st.—The irritating discharge from the diseased bone prevents the entire healing of the ulcer, especially at its lower edge. The thickness and induration of the cheek have subsided, and the child opens his mouth easily, and is able to take food and drink readily without any of it escaping through the aperture in the cheek. Health remains good.

When the irritation from the bone has ceased, and the ulcer is quite healed, a good opportunity will be afforded for a autoplastic operation.

It is impossible to state whether or not the chlorate of potassa exerted any influence towards the recovery.

Case II.—Softening of the Brain from Thrombus, resulting in Hemiplegia and Death.—(Services of H. S. Smith, M.D., and James Crane, M.D.)—Joseph T., seaman, aged 29, native of England. Admitted Oct. 2, 1865. History meagre. A friend said that the patient had been feeling poorly for a few days, and was lying down, when he suddenly lost power of the whole right side, suffering a temporary unconsciousness. No traumatic cause. No exposure to heat or effects of alcohol. Never had rheumatism. Had no premonitory head symptoms. On admission, had facial paralysis; face drawn to left side; tongue turned to right when protruded; partial loss of power in right orbicularis palpebrarum; partial loss of power of articulation; voice very thick; has good sensation and warmth on right side as well as on left; inclined to somnolency; passages natural.

Until Nov. 13th he improved, so that the tongue was protruded more directly. He could move the leg and foot a little, and had made some slight movement of the arm. The bowels were generally very sluggish, but when freely moved, the patient was much brighter. The inclination to sleep continued.

Nov. 13.—A change occurred. The *left* side of his body became cold, while the right side retained its natural warmth, and had increased power of motion. No loss of motion on left side. 14th.—Very dull. Did not respond when addressed. Left conjunctiva inflamed. Bowels inactive. 15th to 17th.—Comatose. Respiration stertorous and labored; face flushed; head hot. Body motionless. 18th.—Died without change of symptoms.

Autopsy.—The two middle cerebral arteries were found occluded by firmly adherent clots at points close to their origin from the internal carotids. Arteritis had existed in each vessel, leading to thickening of the walls, and the formation of a thrombus. The clot on the left side was larger than the other, and quite pale; that on the right side was dark, and extended a short distance into the anterior cerebral artery. By the microscope no atheroma was found in the arterial walls. The left corpus striatum was softened, and of a darker color than is usual.

BELLEVUE HOSPITAL

PROF. F. H. HAMILTON'S CLINICS.

I. Cheiloplastic Operation. II. Traumatic Arteritis of Elbow.—Amputation.

Reported by J. Winslow.

Wednesday, January 3, 1866

I. *Cheiloplastic Operation.*—J. F., æt. 33, laborer, contracted syphilis fifteen years ago, which resulted in subsequent loss of alæ and columna nasi, part of velum palati, part of superior and whole of inferior labium. The saliva was constantly escaping, and this was the patient's chief annoyance. Dr. Hamilton thought the constitutional disease was eradicated, the indolent ulcers on the face being probably dependent upon tension of the skin from contraction of old cicatrices. He proposed to restore the lower lip, and remarked upon the operation as follows:

"This is among the most difficult of anaplastic operations, from the impossibility of supporting the upper edge of the flap, which, accordingly, always contracts; a strip of skin an inch in breadth often shrinking to a line or two. I shall vary the incisions somewhat from any I have yet made or seen, with the object of leaving the gaps in the integument distant from the mouth and towards the sides, that their cicatrization may not draw down its angles."

Operation.—Patient etherized.—The upper margin of remains of lower lip was first refreshed, when an incision was made, passing on either side, from just above angle of mouth, first slightly upwards, then successively outwards, downwards, and inwards, to a point one inch below mental foramen, forming a circular arc of about 240°, with a radius of $1\frac{1}{2}$ inches, and centre at proximate angle of mental process. The flaps, embracing whole thickness of cheek, were dissected up, as far as anterior border of buccinator, and thence became more superficial. Facial arteries sacrificed. Parts very vascular. These flaps were slid around so as to bring their margins consecutively, first, upon scarified edge of lip, next, together in median line; and finally, into the position of the lost lip. The flaps in integument left about half an inch anterior and inferior to angles of jaw. Silver sutures were then inserted, after which a simple cerate dressing, with a light compress, was applied. "It is impracticable to secure a covering of mucous membrane for the new lip; but as the upper lip is not abraded, there is no danger of adhesions between the two. As the flaps are formed partly of cicatricial tissue, we may anticipate a little sloughing.

"In a former case of cheiloplasty, in which also a necrosed portion of the inferior maxilla required removal (the effect of homœopathic treatment), I slid the flaps from below upwards, in the direction opposite to that of the present operation, and, after securing them together on the median line, firmly stitched their lower

portions to the alveolar periosteum. The resulting lip did not completely cover the teeth, but served to retain the saliva.

"There are three principal methods to be adopted in plastic surgery—1, by sliding; 2, by torsion; and, 3, by transplantation. I have operated by the last method in seven cases, for the cure of intractable ulcers of the leg, taking the skin from the other leg, and with complete success. Some ulcers are persistent from constitutional cachexia, but others from deficiency of integument. New skin is formed only from the margin of the old, and will not extend from this beyond an inch or an inch and a half. To cover larger abrasions, the cicatrix contracts; and where a limb is completely denuded, no attempt is made at repair. Asserted exceptions to this rule are not well established."

SATURDAY, JANUARY 6, 1866.

Traumatic Arthritis of Elbow.—Amputation.—W. D., æt. 28, sailmaker. Admitted Dec. 22d. Contusion of left elbow, by recoil of a Parrot gun, July, 1865, followed by swelling about the joint, with persistent stiffness and lameness. Three weeks ago the inflammation suddenly increased, and suppuration occurred. At present there is much debility, with considerable irritative fever, which is rather increasing.

Ether administered. Exploration reveals caries and necrosis of all the articular surfaces; integument moderately healthy. Resection attempted by an H-incision. Humerus sawn immediately above condyles; ulna below olecranon and coronoid processes, and above insertion of brachialis anticus; radius above bicipital tuberosity; muscular attachments carefully preserved; exposed cancellated tissue of humerus and ulna apparently healthy; radius shows osteo-myelitis, and is again divided three inches lower, with like result. Amputation is then decided upon and performed. Antero-posterior flaps from middle third of arm; bone sawed at junction of middle with upper third, where medulla is found softened, though of normal color. Three ligatures, silk sutures, cerate dressing, and roller.

Dissection of the amputated limb disclosed a sinus extending along the dorsal aspect, or inner side of radius, for its whole length, with a large collection of pus near carpus; radial periosteum easily detached; ulnar unaffected. Prognosis unfavorable; but amputation gives the only chance for recovery. Flap operation performed, because the patient's condition demanded a speedy removal of the ether.

"The muscles, though apparently redundant, will retract soon after the effect of the ether has ceased. For Petit's tourniquet the pad should be a firm flat compress, which is more readily adjusted and less liable to displacement than the roller of late so much employed. Place it, if possible, under the frame.

"Cases favorable for resection are those in which the caries is quite limited, and there is little inflammation of the soft tissues, as often in strumous children. Here this operation saves the patient from the dangers of protracted suppuration; and the resulting arm is more serviceable than the anchylosed limb, which always must be expected, in the event of recovery, without surgical aid. Cases of simple but persistent synovitis, with limited ulceration, often do well by merely laying the joint freely open; the synovial membrane soon losing its secreting character and throwing out granulations. Anchylosis is the usual result; but limited motion may sometimes be obtained. Resection is less dangerous than amputation only when it demands less extensive division of tissue. Where the surfaces exposed by the two operations would be equal, the former is perhaps the more hazardous. At the *shoulder-joint* military practice has, in my experience, shown rather greater mortality after resection; which I attribute to the deep burrowing of pus liable to occur after gunshot injuries of this region. At the *elbow* both operations have given, perhaps, about an equal percentage of recoveries. At the *hip*, military statistics, though not decisive, slightly favor resection. The conditions of military and of civil practice here widely differ. After a wound, hæmorrhage and inflammatory effusion may rapidly distend the thigh to double its normal size; the incisions must be large and deep, and are attended, usually, with severe hæmorrhage; the enucleation of the bone, also, from its periosteum is difficult and tedious. In coxalgia the parts are atrophied, requiring a comparatively small incision, and the periosteum is already separated. Of nine cases of resection of the *knee-joint* reported during the war, eight ended fatally, and the successful operation was one of small extent. The Crimean experience gave no successful cases. Amputation is here by no means so dangerous; but were it equally so, it should still be preferred, a Hudson's leg being far better than a stiff knee; and anchylosis is the only favorable issue of excision, as the attempt to get motion would generally compromise life. Many years ago I called attention to the advantages of resection in *compound dislocations of the ankle-joint*. The ancient rule was to leave the luxation unreduced, with all its attendant deformity, lest fatal consequences should ensue upon its reduction. And, indeed, the dangers of this were hardly exaggerated. The soft tissues are not only lacerated, but terribly contused, by the forcing through them of the broad smooth bone. Intense inflammation is sure to supervene, producing contraction of all these tissues—which again reacts to increase the inflammation—and ending in exhaustive suppuration, gangrene, or tetanus. The resection of an inch or an inch and a half of the tibia relaxes the parts, putting them in a favorable condition for repair. The limb thus obtained is more nearly straight, and the liability to anchylosis is greatly diminished; while in every instance I have known of recovery after simple reduction of a compound dislocation of the ankle-joint, anchylosis has been nearly or quite complete. In none of the resected cases has there not been considerable freedom of motion, and in many—*e. g.* two of my own—this is almost perfect.

Progress of Medical Science.

Removal of the Arm, Clavicle and Portion (remaining from a previous operation) *of the Scapula for a Recurring Tumor*, by Mr. Fergusson.—The subject of this operation was a young woman, who, in Jan. 7, 1865, had the lower two-thirds of her scapula removed for recurring fibroid disease. The patient did well for some months after the operation, when the reappearance of the disease was noticed in a tumefaction under the pectoral muscle. This swelling rapidly increased, so that all the hollows around the shoulder were filled up by an evenly diffused mass of disease. The health of the girl becoming seriously compromised by the extension of the disease, it was determined to rid her of the tumor, and as this only could be accomplished by the removal of the whole upper extremity, an operation was performed, which is detailed as follows in the *Lancet:*

"The patient having been placed under chloroform, a grooved needle was thrust into the upper part of the tumor a little below the clavicle, at a point where it seemed just possible, from an obscure sense of fluctuation, that fluid was present. There was, however, none. A small incision was then made over and along

the clavicle about an inch and a half external to the sterno-clavicular joint, through which the bone was divided by the saw and cutting pliers. The object of this, as Mr. Fergusson afterwards explained, was to allow free movement of the shoulder during the ensuing steps of the operation, without causing any strain upon the sterno-clavicular joint. By this step, too, implying the preservation of the inner end of the clavicle, the sterno-mastoid muscle was reserved entire. An assistant (Mr. Wood) then thrust his thumb through this wound and compressed the subclavian artery upon the first rib. Next, the incision was continued along the clavicle, at first outwards, then backwards over the acromion, and lastly downwards and forwards, so as to terminate in the inner and upper part of the arm below the axilla. From the point where this incision, leaving the clavicle, tended backwards, another was made passing down in front of the shoulder-joint, and meeting the first at an acute angle. By these means two semilunar flaps were formed, one before and the other behind, and the skin of the axilla was preserved. The tumor having been exposed by dissecting the flaps from its surface, the muscular structures which attached it to the trunk were divided. There still remained to be accomplished the section of the subclavian vessels and the accompanying nerves, and this was the most delicate part of the operation. Behind the clavicle the tumor was less distinct than at any other parts, spreading vaguely amongst the tissues, and rendering it doubtful at first how far it might extend amongst the muscles of the neck. A careful dissection succeeded in completely isolating it. The mass was then drawn forwards, and the subclavian artery was compressed. In order to obviate the chance of slipping, a strong forceps, such as is used for removing sequestra, had been prepared by having its teeth covered with wash-leather. The blades of this were pushed from behind forwards so as to inclose the subclavian vessels, and another instrument of the like kind was pushed from before backwards with a similar object. Thanks to these, which admirably answered their purpose, there was no difficulty in retaining and ligaturing the artery, and the operation was completed by finally dividing the remaining tissues, chiefly nerves and vessels, outside of these blades, with the loss of scarcely a tablespoonful of blood. For precaution's sake, ligatures were applied to two or three other vessels, but they were scarcely needed. The flaps were then brought together, sutures applied, and the patient removed."

The Origin and Causes of Cholera.—Dr. Barth, one of the physicians of the Hôtel Dieu, who had charge of the cholera patients in that institution, has recently delivered a lecture founded upon observations made during the epidemic of cholera in Paris. He believes that the three former attacks of cholera which have visited Paris can be traced to the Ganges as their starting-point; but that the last epidemic evidently took its origin from the pilgrims at Mecca. He is of the opinion that the disease is propagated by means of germs in the atmosphere, having their origin in noxious emanations, and that they are borne by currents of the air from place to place, and are conveyed from port to port on shipboard. A person has no surety against a second or even a third seizure. Among the most marked predisposing causes, he mentions a high temperature; living in low, damp regions; eating improper food, especially fruit; depression of health and spirits, such as follows, for instance, an attack of typhoid, typhus, and rheumatic fevers.

Character of the Flocculi in the Rice-Water Stools of Cholera.—Dr. Geo. Johnson (*British Medical Journal*) says:—"The flocculi in the rice-water stools consist almost entirely of perfectly organized epithelial scales, most of them of large size. Of this fact I have satisfied myself by repeated examinations of the discharges of different patients. The peculiar creamy, viscid secretion which sometimes nearly fills the small intestines after death, is also almost entirely made up of the same fully-formed epithelium. Now, it is obvious that this large amount of epithelium cannot be explained by the peeling away of one or two layers of cells from the surface of the mucous membrane—the result of a local irritation during life, or by maceration by the fluid contents of the bowel after death. This abundant cell-formation can result only from a very active vital effort; and if the object of that cell-growth be not to withdraw from the blood some morbid products—some constituents of the blood or of the tissues that have been damaged by the morbid poison—it is difficult to suggest any explanation of the phenomena."

Treatment of Acne.—Mr. Joseph Morris, M.R.C.S., sends a short communication to the *Lancet*, in which he extols the virtues of the following application as a remedy for acne:—"It consists," says he, "of sulphur, two drachms; rectified spirits of wine, one ounce: the mixture to be well shaken, and applied to the spots night and morning, the face having been previously washed with warm water and medicinal soft soap. The disease may appear at first to be somewhat aggravated by the application, but a persistence in the use for three or four weeks will eradicate it. Why the preparation of sulphur with spirit should be so efficacious in the treatment of this disease I cannot say, as in two very aggravated cases, existing for seven and nine years respectively (both wives of medical men, under my care), after trying various other remedies, especially the sulpher, the disease did not yield until I treated them with the above."

Instantaneous Cure of Coryza.—An army surgeon, M. Luc, seized with very bad coryza, attended by fever, severe cephalalgia, and excessive secretion, determined upon trying the effect of the inhalation of iodine vapor. The coryza first appeared at 9 A.M., and the inhalations were commenced at 3 P.M., being repeated every three minutes during an hour, each lasting about a minute. The headache was first relieved, the sneezing then occurring seldomer, the amount of secretion diminishing, and by 6 P.M. all traces of the coryza had disappeared, except a little burning sensation in the throat. Several of the officers have since tried the means with the same results. The inhalation is effected by placing a bottle of tincture under the nose, the hand supplying warmth enough to vaporize the iodine.—*Rev. Med., Aug.* 31.—*Med. Times and Gaz., Nov* 11, 1865.

Relative Temperature of Arterial and Venous Blood.—M. Colin records some very remarkable experiments proving that the blood in the left side of the heart is warmer than that of the right. He introduced delicate thermometers into the chambers of the heart, and into the great vessels, and found, as Bernard and others believe, that the temperature of the blood is far from being uniform. The two kinds of blood have not the same temperature. This is true of all parts, regional and central, as a rule, except that, in the depth of large organs, the blood of the artery is warmer than that of the accompanying vein. The blood of the carotid, for example, is half, one, or two degrees warmer than that of the jugular; the same thing may be said of the femoral artery and saphena vein, and of the radical vessels. In the arterial system the temperature diminishes

from the centre to the extremities, and in the veins it increases from the radicles to the centre. Each great vein has its own temperature: the superior vena cava affords the minimum, the vena portæ the maximum, and the inferior vena cava presents an intermediate degree. M. Colin found the blood in the left ventricle to be in fifty out of eighty cases considerably warmer than that of the right chambers. Hence he concludes that the lungs play an important part in the development of heat.—(*Lancet, Nov.* 25, 1865.)

Conveyance of Miasmic Poisons.—According to the opinions of M. Zagrill, a physician in Cairo, the poison of cholera is conveyed in minute particles by the wind. This is why it often passes over certain villages without attacking them; the molecules, when propelled by a violent storm, are retained at a certain distance from the ground, in exactly the same manner as locusts, which, carried by the wind, traverse certain localities without committing the slightest ravages. This, in the writer's opinion, is also the reason why the epidemic first makes its appearance in the night; at that time the wind abates, and the molecules are deposited.—(*Lancet, Nov.* 25.)

The Development of Muscular Fibre.—Dr. Wilson Fox has recently published some researches upon the development of muscular fibre, which are of some interest so far as they tend to endorse the cell theory of Schwann. He noticed in the tadpole that the earliest appearance of the fibre was made known by an oval body, containing nuclei and nucleoli, which body he calls a cell. These cells so-called, elongate with or without division of their nuclei, and after a while lose their pigment; exhibiting the characteristic transverse and longitudinal striation which belongs to the perfectly formed fibre. The striation, according to his views, takes place within the cell, and the myolema is nothing more than an elongation of the cell wall.

Perforation of the Membrana Tympani for the Cure of Deafness.—Dr. Gruber, Aural Surgeon in the Vienna General Hospital, has revived Sir Astley Cooper's operation of perforating the membrana tympani in certain forms of deafness, attended with very annoying tinnitus aurium. His success in two cases was very striking, and in others was sufficiently good to justify and encourage the repetition of the operation.—*Archiv für Ohrenheilkunde.*

An Agreeable Anæsthetic.—Mr. Baker Brown, jr., at a late meeting of the Obstetrical Society of London, exhibited a compound made up of two parts of chloroform with one of alcohol, to which the distilled essence of eau-de-cologne had been added, and remarked that he had used it with happy effect in allaying the pain of labor without producing complete anæsthesia.

Removal of Spleen by Operation.——Mr. Spencer Wells successfully removed, Nov. 20th, a hypertrophied spleen from a married woman, 34 years of age. It weighed six pounds and four ounces. This is the first time the operation has been performed in England, and only the third time in the history of surgery. The two other operations were performed in Germany, the subjects surviving only a few hours. The patient, at the latest account, 48 hours after the operation, was reported doing "as well as could be expected."

Trichinous Disease has lately been raging in Berlin, caused by the eating of uncooked pork. A large number of fatal cases have been reported.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, Jan. 10, 1866.

Dr. Gurdon Buck, President, in the Chair.

Cancer of Rectum—Operation—Peritonitis—Death.

Dr. L. Voss exhibited the lower portion of the rectum removed by operation from a woman 32 years of age, who had been affected with cancerous disease of that part. He gave the following history:—She had always enjoyed a fair measure of health, and did not have any hereditary tendency to disease. She had several children and menstruated regularly. During the summer of 1864 she lived on Staten Island, and, with her husband and two or three of her children, suffered from dysentery. She, however, recovered without experiencing any trouble in defecation. Her suffering from the present disease began about nine months ago, and when I saw her about the end of November last she was, in consequence of the ravages of the disease, very much reduced in flesh. On introducing my finger into the rectum I discovered, about three quarters of an inch above the anus, an ulcer, with hard margins, painful on pressure, and with a strong tendency to bleed on the slightest provocation. The whole circumference of the gut, with the exception of a small portion on the right posterior part, was involved in the disease. The ulcer did not reach above a point two and a half or three inches from the anus. There was no[t], as is very frequently the case under such circumstances, any stricture of the rectum. The probable fatal result of the case was told the husband, and an operation was proposed as the only chance for the salvation of the patient. The husband consented to the measure. In the course of ten days afterwards the operation was performed by drawing down the diseased portion and excising it, cutting the sound rectum above completely across. The cut portion of the healthy gut was then brought down and attached to the cut margin of the anus. The patient did well until the fourth day after the operadtion, when peritonitis set in, and she died at the end of six and a half days after the operation. I have some reason to believe that if she had been kept properly under the influence of opium in the meanwhile, the peritonitis would have been controlled. The peritonitis was evidently the result of the local injury inflicted by the operation. The cancer, on examination after removal, proved to be of the villous variety. It was confined entirely to the parietes of the rectum. The operation was easy in its performance, when taken into account in connexion with a similar operation which I performed some time ago on a man. The parts around the anus were very lax and dilatable, and rendered the operation comparatively easy; there being ample room for the introduction of the bistoury and scissors. The hæmorrhage was in no way alarming, not even abundant. The patient was placed in the position for lithotomy. There was not the slightest disposition to secondary hæmorrhage.

In answer to a question from Dr. Bauer, he stated that there had been no autopsy made.

Dr. Bauer then remarked that there was no certainty but that ulcerations existed higher up, and that one of these had perforated the gut and had given rise to the peritoneal inflammation; and in that connexion he referred to a case that had occurred to him in which a speedy death from peritonitis was caused by such an accident. In this case he discovered a moderate stricture about three inches above the sphincter. This stricture at first,

to all appearances, seemed to be impervious, and he advised that it first be divided, and afterwards that the parts be dilated. The advice being accepted, an incision was made through the membranous portion of the stricture with great ease and without any accident. Subsequently, one or two injections were administered, and they did not return. When the lady recovered from the effects of the chloroform she complained of intense pain in the abdomen; and this, as was afterwards proved on the first visit after the operation, was due to the existence of peritonitis. Marked emesis being one of the symptoms, opium had to be administered by enemata. In the course of thirty-six hours afterwards the patient was a corpse.

On post-mortem examination, the rectum was found covered, for a space of nine or ten inches, with ulcerations, one of which had perforated the intestine, evidently as the direct result of the injections used. The other ulcerations were discovered to be in different degrees of development; and while some were found only to the depth of the mucous membrane, others were discovered to extend through the muscular layer. The injections were found in the abdominal cavity.

Dr. Voss remarked that as cancerous ulcers of the rectum were for the most part continuous, and as there was a positive limit to the ulceration in the case presented, he did not think he had a right to suppose that others that were likewise so isolated were higher up.

Dr. Bauer was aware of the fact that epithetial cancers in the rectum were, as a rule, continuous; but he had met with exceptions. The operation in Dr. Voss's case seemed to be very slight, and he could not see why the peritonitis should follow so rapidly afterwards, unless there was some other explanation for its occurrence.

Dr. Voss remarked that the operation, because it was not a troublesome one, was not necessarily any the less a dangerous or severe one. He had always believed that peritonitis was one of the most common attendants of the operation.

(*To be continued.*)

Improvements in Instruments.

STEARNS' URETHRAL DILATOR.

This instrument (Fig. 1), manufactured by Messrs Tiemann & Co., was devised by Surgeon Stearns, U.S.A., for the purpose of forcibly dilating strictures of the urethra. It is composed of a staff, handle, and screw. The staff is curved to the same shape as an ordinary steel bougie, and consists of two strands of galvanized steel wire, forming one piece by being folded at the extremity of the curve. When the instrument is to be introduced into the urethra, these two portions or strands are perfectly adapted to each other, until the extremity of the staff is either engaged into the stricture or passes through it a certain distance. The wires are then separated from each other by the motion of the screw arrangement near the handle, which draws upon one strand, and straightens out its curve. The degree of separation can be nicely regulated by means of this screw; and by the use of a thin slide any particular portion of the staff can be acted upon. For instance, if the dilatation is to be made near the extremity of the instrument, the slide is placed but a short distance from the point of the staff; and if the stricture will allow of the passage of the staff for a considerable distance through it, the slide is kept nearer the handle of the instrument. The power which this instrument possesses is, on account of the action of the screw, very remarkable.

Fig. 2.

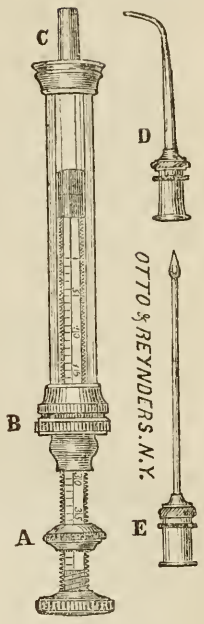

Fig. 3.

LIVINGSTON'S SPRING CAUSTIC PROBE.

(Geo. Tiemann & Co.)

The construction of this instrument can at once be understood by a reference to the woodcut (Fig. 2). In a word, it consists of a small canula, which contains a very sensitive silver spiral spring attached to the end of a delicate probe. It was devised by Dr. Livingston, of this city, for the purpose of applying caustic to delicate membranes. All the preparation required is the coating of the end of the probe with caustic, previously fused.

Dr. L. Thus speaks of the instrument:—

"The 'Spring Caustic Probe' was suggested by the difficulties I encountered in treating disease of the membrana tympani. Every one who has attempted to cauterise an ulcer of this organ must have experienced the difficulty of estimating, accurately, the distance from the caustic to the point of application through the narrow canal. Hence the utmost caution must be used, lest the delicate membrane be destroyed by the very means employed to free it from disease; and by the exercise of the requisite care, the operation is usually very imperfectly performed. But with the instrument in question, no fear of doing harm need be entertained, as the *spring* is so sensitive as to yield before any injuy can be done to the most delicate organ. I have used the instrument in many cases, and with much satisfaction, especially in children, where it is so difficult to obtain quietness for any

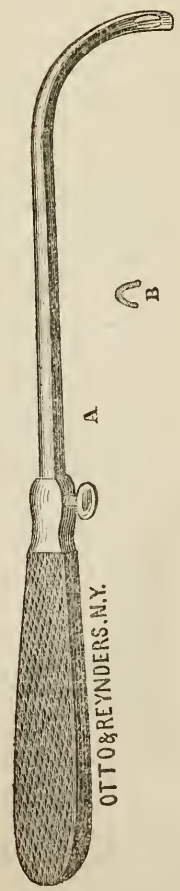

Fig. 4.

prolonged operation. A moment will suffice to get the range, and to thrust the probe upon the diseased point without any hesitation for fear of results."

LUER'S IMPROVED HYPODERMIC SYRINGE.

This instrument (Fig. 3) is an important modification of the hypodermic syringe, and was obtained by Mr. Reynders, of this city, from Mr. Luer, of Paris.

The barrel of the syringe has the capacity of forty minims, and the piston is graduated for each drop. A female screw (A) is made to run upon this piston and stop its progress at any given point, according to the number of drops that are required to be injected. By this arrangement not only is the amount of injection exactly regulated, but the same syringeful, by successively moving the screw towards the piston, can be made to serve a number of patients until the whole is used up. It also has an adaptation (D) for injecting the lachrymal sac.

OLLIER'S PERIOSTEUM PROTECTOR.

This very simple and useful instrument (Fig. 4) has been devised by Ollier, for the purpose of detach ng the periosteum from the bone, and of protecting that membrane from injury by the chain-saw, and is more especially adapted to resections. The staff is flattened at its extremity for obvious reasons, and except at this point, is grooved upon its concave surface throughout its whole length. The handle is perforated longitudinally, and allows of the sliding of the staff within it. This arrangement is for the purpose of lengthening or shortening the instrument, according to the necessities of the case, the staff being firmly fixed in a given position by means of the screw in the handle. The staff is passed with its concave surface next to the bone, and by careful and gradual manipulation the periosteum is separated, after which the chain-saw is passed between the bone and instrument through the groove, and is afterwards worked in it. The relative depth of the groove is represented at (B.) The instrument is manufactured by Otto & Reynders.

New Publications.

ANNOUNCEMENTS OF NEW BOOKS.

The following named new works are announced as in preparation by

HENRY C. LEA, Philadelphia:
Flint's Practice of Medicine. 8vo.
Pereira's Materia Medica, abridged. 8vo.
Roberts on Urinary and Renal Diseases.

WILLIAM WOOD & COMPANY, New York:
Sims, J. Marion, on Uterine Surgery. 8vo., illustrated.
Garrod on the Action of Medicine. 8vo.
Burrall on Cholera. 12mo.
Foster on Dyspepsia. 12mo.

LINDSAY & BLAKISTON, Philadelphia:
Aitken's Practice of Medicine. 2 vols. 8vo.
Beale on the Microscope.
Hoffman's Introduction to Modern Chemistry.
Noad's Students' Text-Book of Electricity.

D. APPLETON & Co.:
Flint, A., Jr., A System of Physiology. 8vo.

BOOKS AND PAMPHLETS RECEIVED.

LECTURES ON EPILEPSY, PAIN, PARALYSIS, and certain other Disorders of the Nervous System, by CHARLES BLAND RADCLIFFE, M.D., Fellow of Royal College of Physicians of London, Physician to the Westminster Hospital, &c. Philadelphia: Lindsay & Blakiston, 1866.

STIMULANTS AND NARCOTICS, their Mutual Relations, with Special Researches on the Action of Alcohol, Ether, and Chloroform on the Vital Organism, by FRANCIS E. ANSTIE, M.D., M.R.C.P., Assistant Physician to Westminster Hospital, Lecturer on Materia Medica and Therapeutics to the School, and formerly Lecturer on Toxicology. Philadelphia: Lindsay & Blakiston, 1865.

SUCCESSFUL REMOVAL OF THE UTERUS AND BOTH OVARIES BY ABDOMINAL SECTION, the tumor, fibro-cystic, weighing thirty-seven pounds, by HORATIO ROBINSON STORER, M.D., of Boston, Assistant in Obstetrics and Medical Jurisprudence in Harvard University, Surgeon to New England Hospital for Women, &c. 8vo. pp. 32. From author.

CONTRIBUTIONS TO BONE AND NERVE SURGERY, by J. C. NOTT, M D., Professor of Surgery in Mobile Medical College. Philadelphia: J. B. Lippincott & Co., 1866.

LECTURES ON INFLAMMATION, being the first course delivered before the College of Physicians of Philadelphia, under the bequest of Dr. Mütter, by JOHN H. PACKARD, M.D., author of a "Manual on Minor Surgery," translator of Malgaigne's "Traité des Fractures," Secretary of the College of Physicians, &c., &c. Philadelphia: J. B. Lippincott & Co., 1865.

LECTURES ON VENEREAL DISEASES, by WILLIAM A. HAMMOND, M.D. Philadelphia: J. B. Lippincott & Co., 1864.

CIRCULAR No. 6. WAR DEPARTMENT AND SURGEON-GENERAL'S OFFICE. Washington, Nov. 1, 1865. Reports on the extent and nature of the materials available for the preparation of a medical and surgical history of the Rebellion. Printed for the Surgeon-General's Office by J. B. Lippincott & Co. Philadelphia, 1865. (From Surgeon-General, U.S.A.)

TRANSACTIONS OF THE MEDICAL SOCIETY of the State of New York for the year 1865. (From Dr. N. C. Husted.)

Medical News.

APPOINTMENTS.

COLLEGE PHYSICIANS AND SURGEONS, N. Y.—Dr. T. G. THOMAS has been elected to fill the chair of obstetrics rendered vacant by the death of Prof. Chandler R. Gilman.

NEW YORK EYE INFIRMARY.—Dr. R. F. WEIR has been appointed Aural Surgeon to the New York Eye and Ear Infirmary, to fill one of the vacancies occasioned by the resignations of Drs. Roosa and Hinton.

DELEGATES TO THE STATE MEDICAL SOCIETY FROM NEW YORK CITY.—The following are the names of the delegates from this city to the State Medical Society, so far as we have been able to ascertain: From N. Y. Academy of Medicine, Drs. J. L Banks, J. H. Hinton, Geo. F. Shrady, H. D. Noyes, and H. P. Farnum; from the N. Y. County Medical Society, Drs. W. N. Blakeman, James L. Brown, James J. Connolly, Louis Elsberg, Guido Furman, Chas. Henschell, Saml. T. Hubbard, James Kennedy, Jonas P. Loines, John B. McEwen, James O. Pond, W. H. Thomson, A. Underhill, John R. Van Kleek, and Jerome C. Smith. Drs. William B. Bibbins and Lewis A. Sayre were elected to fill vacancies.

NEW OFFICERS FOR THE N. Y. ACADEMY OF MEDICINE.—The following gentlemen were elected to fill those vacancies which have occurred during the past year, by reason of expiration of term of service: Dr. O. White as Vice-President; Dr. A. Underhill as Trustee; Dr. W. H. Draper, member of Committee on Admissions; Drs. E. R. Peaslee and J. O. Stone, members of Committee on Ethics; and Dr. A. Clark, member of Committee on Education.

EAST RIVER MEDICAL ASSOCIATION.—A new association, entitled the East River Medical Association, has lately been organized on the east side of the town, its object being the discussion of medical subjects in general. Dr. John Hart is the Pres't, and Dr. John Shrady, Sec'y.

Original Communications.

PAPERS UPON VENEREAL DISEASES.

By F. J. BUMSTEAD, M.D.

No. I.

Review of the Evidence upon which is based our Belief in the Existence of two Diseases in the "Syphilis," of Fifteen Years ago (1851).

In the history of medicine there has rarely been so radical a change of opinion in so short a space of time as has taken place within the last few years relative to those diseases which were recently known under the common name of "Syphilis." Notwithstanding the general acceptance of the "new ideas" upon this subject, however, doubters and cavillers are still to be met with.

Some of these are probably incorrigible. Within five years, an eminent professor in a medical college wound up a discussion between us on the simple nature of gonorrhœa, with the remark: "Well, Doctor, I have taught the doctrine opposite to yours too long to be able to change." If advocates of the idea that gonorrhœa is dependent upon the syphilitic virus can still be found, we may well despair of leading *all* one step further. Instances of this kind must, however, be rare; and it is with the hope of convincing those not yet convinced, but still "open to conviction," that I offer the following remarks upon the evidence of the existence of two diseases in what was known as "syphilis" fifteen years ago; and I propose to subject this evidence to the same laws as are generally recognised as decisive in the classification of the various departments of Natural Science. As will be seen before we conclude, if the subject of this paper were adapted to a sermon, the appropriate text would be: "For every tree is known by his own fruit."

Let us remark at the outset, that the basis of all classification in Natural History is the perpetuity of certain characteristic traits in successive generations. "Like produces like." If the seeds of the tulip sometimes produced a rose, or the progeny of the eagle were occasionally sparrows, or if the members of every genus and species of the animal and vegetable kingdom could not be relied upon to produce their like, then would classification cease. It is true that hybrids exist; but they are either incapable of reproduction, or else in a few generations they revert to the original type.

Let it also be observed that the distinctive marks of genera and species are not necessarily patent in all stages of development, and that it is not at all uncommon for them to be entirely absent or undiscernible in the earlier stages. It would be impossible to classify animals and vegetables, in many instances, simply from inspection of their ova or seeds. The young of many birds of different species cannot be distinguished. Immature specimens of mosses, carices, and of other natural families of the vegetable kingdom, are of but little use to the botanist, who wants the fruit in order to identify the species. It has not occurred to any one, however, to found upon this fact an attempt to overthrow the value of classification in general. It is universally recognised as sufficient that well marked specific differences exist at some period in the development of the species, and especially in their maturity. Their absence, or perhaps our inability to recognise the same in certain stages, particularly the earlier, does not lead us to throw classification aside.

In pathology, the laws of classification are necessarily much less definite, the distinctive features of various diseases much more obscure, than obtains in Natural Science. Our means for observation are less perfect. Extraneous influences, modifying the type, are more numerous. Hybrids are frequent, and the elements of the cross or combination often difficult of separation. Hence the frequent disputes with regard to the identity or non-identity of two diseases—as, for instance, typhoid and typhus fevers. Hence the frequent hesitation of the medical practitioner in filling up a death certificate when the patient died from a "complication of diseases." What was the "direct," and what the "indirect cause of death," proves to him a knotty question.

Now, the greater the obscurity cast upon classification of diseases in general by the absence of constant, well defined, and characteristic symptoms, the greater the value of such symptoms when they exist; and when thus, in pathology, we can attain, or approximate to, the accuracy of Natural Science.

And here lies the stand-point of those who believe and advocate the existence of two diseases in the "syphilis" of fifteen years ago. We claim for our distinction the same kind of proof that is employed by students of Natural Science in their classification —viz. the presence of characteristic traits which are constant from one generation to the other. We claim, in short, that if a naturalist have a right to separate a rhinoceros from a mouse, or a heron from a bobolink, we have the same right to recognise two diseases in the "syphilis" of our medical pupilage.

The characteristic traits upon which this claim is founded are separated by the broad distinction of a local character upon the one hand, and a general or constitutional character upon the other. What greater difference were possible?

For many years prior to 1852, the fact that the effect of "syphilitic infection" was sometimes limited to the point of inoculation and its immediate neighborhood, and that sometimes it extended to the whole system, was regarded as due to some peculiar idiosyncrasy of the individual. No attempt was made, however, to specify in what this peculiarity consisted, or to explain the strange fact that the same person, with constitution and idiosyncrasy remaining the same, might, within a short space of time, undergo two exposures with results so radically different as those named.

The fallacy of this explanation was exposed in 1852 by Bassereau, who at the same time showed that the cause of a general disease appearing in one case and a local disease in another, could only be attributed to the nature of the poison communicated in contagion; as proved by the fact that the recipient invariably had the same form, either local or general, as existed in the giver; and that this uniformity of type could be traced back, whenever the opportunity offered, in preceding generations, and its perpetuity be predicted in succeeding generations, with unerring certainty.

It is not my purpose at present to enter into the details of the investigation by which Bassereau arrived at this conclusion, and which I have given elsewhere. Suffice it to say that it was done by a series of "confrontations" of persons receiving and giving venereal diseases, such as could be better carried out in Paris than anywhere else in the world, owing to the extensive venereal hospitals of that city, and the efficiency of the French police; that Bassereau's cases and those subsequently reported by Dron, Diday, Rollet, Rodet, Fournier, Caby, and others, all affording the same testimony, numbered several hundred; and that this result had only to be announced to meet with almost uni-

versal acceptance, so fully did it coincide with the experience, and so perfectly did it satisfy the mind, of nearly every observer. It is upon the character of this proof, however, that I now repeatedly insist—viz. that it is precisely of the same nature as that which is admitted as valid in Natural Science. If I am correct in assuming this position, it must, I believe, be regarded as invincible.

Collateral proof has, indeed, been adduced by Bassereau and others; but it should be regarded only as collateral and secondary. Thus, from a careful examination of medical literature, Bassereau was able to show, satisfactorily to himself and others, that one of these diseases had been known in all ages of which we have any record; whilst the other was unheard of in Europe until about the year 1494, the time of the "Italian epidemic;" and that the two were regarded as distinct by physicians and by writers upon Venereal for thirty years afterwards, when the "age of confusion" commenced.

The proof afforded, also, by an examination of the earliest lesions of the two diseases under consideration, —so far as taken in evidence of their distinct nature— must be regarded as of minor importance, because obtained at that period of development in which characteristic traits are always most obscure and liable to be mistaken; but, above all other reasons, because it cannot touch the main question, the character of the fruit. In a clinical point of view, the case is, of course, different, and this proof is of great importance both in the prognosis and treatment. Fortunate, indeed, is it that it exists, and is so constant and reliable. I do not hesitate to say that our ability to separate the two diseases in the earliest stage of their development is much greater than that of the naturalist to distinguish the young forms of allied species in the animal and vegetable kingdoms; although this is not to be wondered at, because the difference is here, as it were, generic, and not merely one between species. Supposing, however, that the proof referred to were entirely absent, and that we could never distinguish two diseases in the "syphilis" of fifteen years ago in the earlier stage, the evidence in favor of their distinct nature would not be shaken a hair's-breadth.

Differences in "characters," so-called, were recognised for many years prior to 1852, but the two diseases were still confounded, until Bassereau first showed the perpetuity in successive generations of the resulting fruit.

If the preceding remarks be well founded, how unphilosophical, not to say frivolous, are many of the objections urged against the recent views of Venereal Pathology? One or two examples will suffice.

Objector No. 1 says:—"I have a case of a sore upon the penis which appeared two days after coitus, and yet was followed by secondary symptoms. There was no incubation of 'two or three weeks,' such as you claim for true syphilis."

Now, ten chances to one, this objector has never inquired how often, and at what intervals, his patient was exposed previous to the appearance of the disease, and innocently supposes that his infection must be due to his last act of coitus. But suppose that there was no exposure prior to the last for a long period. Was not violence done to the penis in the act, and was not the sore observed two days afterwards, a mere rent or abrasion, in which, kept open by want of cleanliness, the usual symptoms of the initial lesion of syphilis developed themselves at a much later period? Was this point carefully investigated at the time by a competent observer, or does the whole case, as reported, rest upon the statement of an unprofessional patient? Under any circumstances, does the case invalidate the "duality" which we claim? Not in the least.

Objector No. 2 belongs to a more numerous class. He says that his patient had a "soft chancre" upon the penis or vulva, appearing six weeks ago; that the sore was soon followed by a suppurating bubo in the groin; and that now, "contrary to your doctrine," secondary symptoms have appeared.

His (the objector's, not the patient's) case is a serious one, and requires careful management.

We inquire, in the first place, as to the interval which elapsed between the exposure and the development of the sore. Objector probably does not know. He "never thought to inquire."

We ask if he saw the ulcer at an early period of its evolution; is he sure that its base was not then indurated; what was the condition of the inguinal ganglia at that time, before inflammatory action had commenced? Is the patient of a strumous habit, or has he received any recent injury in the groin? The answers to these questions are frequently indefinite and unreliable. Objector convicts himself of imperfect observation, and we may well doubt all of his statements which depend upon a careful use of sight and touch.

Take the case, however, as presented, and see what we can make of it.

Induration of the sore may have been poorly marked, or altogether absent, especially if the patient be a woman; and hence objector's supposition that it was a case of "soft chancre."

Or, there may have been a double inoculation,—inoculation of the virus pertaining to each of the two diseases we are considering, as not unfrequently occurs. This would fully explain the difficult points of the case as presented; the character of the sore itself; the suppurating bubo; the apparent absence of induration of the ganglia buried in the inguinal swelling—and yet the subsequent evolution of the general symptoms of syphilis.

But without such double inoculation, the changes ordinarily effected in the ganglia by the true syphilitic virus afford no protection against inflammatory action. No one has ever asserted that ganglia thus affected cannot inflame and suppurate. The only wonder is, that when thus changed from their normal condition, they are not more susceptible to the influence of a strumous diathesis, undue exercise, or external violence.

Under either of the above suppositions, the patient has evidently been inoculated with the virus of true syphilis; and if objector had examined the person from whom the disease was derived, he would have found traces of the same disease.

Additional illustrations might be given, but these will suffice. In most such cases we find imperfect observation and ignorance of the distinctive marks of the two diseases in their earliest phase, and of the modifications of which they are susceptible; but we find especially the erroneous idea that the existence of two diseases in the "syphilis" of fifteen years ago is based upon evidence afforded by the initial lesions.

To those who, without taking the trouble to study the subject, bring forward cases imperfectly observed, or resting solely upon the statements of patients, in a fault-finding spirit, the only answer to be given is: You are reasoning upon false premises. The tree is known by its fruit. If you wish to overthrow the "modern views" of Venereal Pathology, you must adduce evidence of quite a different character. You must show by a series of cases accurately observed, and judged of in their totality, that the two diseases which

we recognise occur at random, or under the influence of accidental causes, in successive generations.

To the earnest student and inquirer we may say: Doubtful cases at an early period may be met with. The diagnosis may be cleared up by examination of the source of contagion, in which the disease is further advanced, and its characteristic traits better developed. If such examination be impracticable, wait for the fruit.

A CASE OF SPONTANEOUS AMPUTATION IN UTERO.

By OSCAR H. YOUNG, M.D.

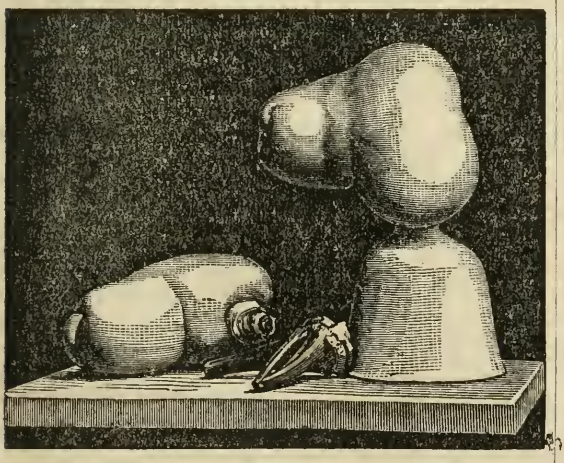
ALBANY, NEW YORK.

On the 19th of May, 1862, a daughter was born to Mr. Rodgers, of Bemis Heights, New York, with a remarkable deformity of the right leg and thigh. The leg was wanting from about four inches below the knee, and the thigh was partially amputated about four and a half inches above the knee-joint.

There are quite a number of cases on record, both of complete and partial spontaneous amputation; but none of them are entirely similar to the present, inasmuch as it illustrates both processes, and that, too, on the same limb.

There was nothing in the condition of the mother during her gestation to account for the deformity of the child. She experienced no shock or injury, nor was she subjected to any fright or other extraordinary mental impression during her pregnancy.

The stump of the amputated leg was completely healed, and was perfect and comely in shape, as though it had been made with the surgeon's knife. The extremity of the stump was covered with smooth normal skin, there being no cicatrix visible excepting a small spot in the centre.



This peculiarity has an important bearing on the question as to the nature of the process by which spontaneous amputation is effected; and it is difficult to examine closely, and reflect upon the appearance of such a stump, without being forced to the conclusion so ingeniously advanced and supported by Dr. Montgomery—viz. that the agent by which the amputation is effected is a *ligature*. In some cases the umbilical cord is found tightly coiled around an arm or a leg, and deeply imbedded in a groove or depression in the soft parts. In other cases the child is born with a limb partially divided, and the depression found to be occupied by a cord of fibrous lymph, an adventitious material thrown out from the placenta or the umbilical cord, or sometimes from the body or members of the fœtus.

In the case of Mr. Rodgers's child there was no abnormal appearance of the umbilical cord, nor any indications of a ligature, excepting its effects.

The integuments were carried inwards, and drawn into a conical form, the continuity of the skin being perfect, with the exception of the small central cicatrix. The subjacent parts would thus be compressed, and after a time the blood-vessels would partake of this compression to such a degree as no longer to be capable of transmitting sufficient blood to maintain the growth of the limb below the constricted part. The bone would necessarily be involved in the process of interstitial absorption, and thus gradually reduced in size and strength, so that it would yield to a very slight force—as, for instance, the motion of the fœtus itself. But a small spot would remain to be cicatrized, where the previously reduced bone and integuments were divided.

The separated part of the limb was very likely present, and might have been found amid the secundines; but no search was made, for the reason that, the room being dark, the deformity escaped the notice of the attending surgeon, and was not known to him until his second visit was made, at which time the secundines had been thrown away.

The *thigh* was partially divided four and a half inches above the knee-joint. The diameter of the constricted part was one and one-third inches, while the limb directly above and below measured three inches in diameter. (These measurements were made when the child was three years and five months old.)

The depression was uniform, and of nearly equal depth around the limb. It was such as would result from the application of a ligature tightly around the child's thigh. The bone was intact, and the blood-vessels not obliterated, which accounts for the natural symmetry of the limb below the depression.

The child was brought to Professor Armsby while very young, and he advised the parents to wait. It was brought to him again when at the age of three years and five months, when the operation was performed. A circular sweep was made with the knife, the tissues were retracted, and the femur divided. One artery was ligated, after which the flaps were united by a single suture, and the dressings completed in the usual manner.

The stump was completely healed at the end of a week; the case having progressed in the most favorable manner.

The amputated portion was dissected, and found perfectly normal. The tibia and fibula were closely approximated at their extremities—viz. where the spontaneous amputation had occurred—and the ends were neatly rounded off.

Annual Reports of Northern and Demilt Dispensaries.—The thirty-ninth annual report of the Trustees of the Northern Dispensary for the year just closed, makes the whole number treated, including about 4000 home visits, 28,663; of these 28,212 were cured or relieved; 318 sent to hospital; 91 died; 17 were discharged as improper subjects, and 25 remained under treatment on December 31, 1865.

The report of the managers of the Demilt Dispensary for the same period, is as follows: Total treated, including 4818 home visits, 37,605; 333 sent to hospital, and 130 died.

In the former institution, 33,395 prescriptions were dispensed; and in the latter, 63,788.

ON THE ADVANTAGES OF THE

EARLY TREATMENT OF FRACTURES OF THE BONES.

By ALFRED C. POST, M.D.,

PROFESSOR OF SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

When I was a medical student, I was taught that recently fractured bones required no other treatment during the first week or ten days, than placing the limb in an easy position on a pillow or cushion, and applying evaporating lotions, and using other simple means for the prevention or relief of inflammation. According to the instructions which I then received, it was worse than useless at that early period, by extension and counter-extension, and various manipulations, to place the fragments in accurate apposition, and to apply bandages and splints, and other apparatus, to maintain the fragments in their proper relative position. It was deemed advantageous to wait until the period for active inflammation had passed before resorting to any systematic measures for securing a proper adaptation of the broken surfaces to each other. Such were the lessons which I received from those to whom I looked as my instructors and guides, as I entered upon the practice of surgery; and at that time I did not question the correctness of the views which were inculcated. But as I began to acquire personal experience in the management of this class of injuries, my confidence in the correctness of the instructions which I had received began to be shaken; and it was not long before I came to the settled conclusion that the methodical treatment of fractures is easier to the surgeon, more comfortable to the patient, and more advantageous in its ultimate results, when it is commenced at the earliest practicable period after the infliction of the injury; and this conviction has been confirmed by a long and ample experience in the treatment of fractures in the New York Hospital, and in private practice. And as some of our teachers of surgery still inculcate what I regard as erroneous ideas on this subject, I have thought proper to present to the profession the results of my observation and experience.

According to my observation, a fractured limb, when merely laid upon a pillow, or supported by cushions, is a source of great discomfort to the patient, who has a painful sense of helplessness and insecurity; being obliged to exercise the utmost vigilance to avoid such movements as will give rise to acute pain. If he fall asleep, he is suddenly aroused by spasmodic twitchings of the muscles, causing the surrounding soft parts to be pricked and irritated by sharp spicula of bone, occasioning great suffering, sometimes amounting to agony. When the limb is left for a week or two without accurate coaptation of the fragments, and only supported by pillows or cushions, the muscles become firmly contracted, and offer great resistance to subsequent efforts to restore the limb to its normal length. The limb becomes otherwise deformed, being bent or twisted, so as to mar its beauty, and often to impair its functions. The deformity thus induced is rendered more intractable by the results of inflammatory action, such as the effusion and organization of fibrine fixing the parts in their abnormal position; and when, at a later period, systematic efforts are made to reduce the fragments to their normal position, much greater pain is inflicted than would have been occasioned by the replacement at an earlier period, and the fragments are not brought as accurately into their proper position as they might have been immediately after the fracture had occurred.

When I am called to a recent fracture, I endeavor, with as little delay as possible, to bring the fragments into an accurate state of coaptation; employing for this purpose extension and counter-extension to such a degree as may be required, together with such manipulations as the condition of the fractured limb may render necessary. I often find it advantageous to administer an anæsthetic to facilitate the reduction of the fracture. Having brought the fragments into apposition, I at once employ such bandages and splints, or permanent extension and counter-extension, or other mechanical support, as may be required to prevent any considerable displacement at the seat of the fracture. I am careful to avoid applying bandages so tightly as to give pain to the patient, or to strangulate the circulation through the limb. I always give directions to the persons who are in immediate charge of the patient to loosen the bandages during my absence, if from swelling of the limb, they become painfully tight. I also make it a point to visit the patient within twelve to twenty-four hours after the first application of the apparatus, for the purpose of re-adjusting it, if necessary. With these precautions, I find that the early treatment of fractures, as indicated, adds greatly to the comfort of the patient; relieving him from his painful sense of helplessness, preventing in a great degree the spasmodic twitchings which often occasion such acute suffering, and diminishing the amount of inflammation consequent upon the injury. My patients uniformly express themselves as relieved by the replacement of the fragments, and by the mechanical support which is afforded to the limb. At this early period there is comparative facility in overcoming the deformity which is occasioned by the fracture, and less active measures are required during the subsequent treatment to prevent a recurrence of the displacement, than if the active treatment had been commenced at a later period. I think also that the early treatment of fractures is advantageous in diminishing the tendency to rigidity of the muscles and articulations. To prevent such rigidity, I am in the habit of frequently re-adjusting the dressings, and cautiously applying passive motion from the beginning.

I am aware that the practice which I have inculcated is liable to abuse, and that irreparable mischief is often the result of the early application of tight bandages in such a manner as to strangulate the circulation, and to occasion mortification of the limb. It would be incomparably better to leave the fractured limb entirely to nature than to bandage it in the manner in which a sailor splices a broken spar. But with the precautions which I have indicated, no such mischievous results will follow; but the comfort of the patient will be greatly promoted, and his limb will be more perfectly restored to its normal shape, and its functions will be more speedily and more perfectly regained.

Services of Officers of Medical Department of Army.—I desire to bear testimony to the ability, courage, and zeal manifested throughout the war by the officers of the Medical Department under all circumstances and upon all occasions. With hardly an exception, they have been actuated by the highest motives of national and professional pride, and the number who have been killed and wounded bears most honorable testimony to their devotion to duty on the field of battle.—*Annual Report of Surgeon-General U. S. A., for* 1865.

Original Lectures.

ON CHOLERA.

By A. CLARK, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

Lecture I.

The Pathological Anatomy of Cholera—Appearances of the body of a person who has died of the disease—Curious phenomena sometimes developed in connexion with muscular contraction—Post-mortem changes in Brain, Stomach, Large and Small Intestines.

Far off in the East, for centuries, there had been nursed a disease which was destined to become a scourge to the world. It was retained within that eastern region, so far as we at present know, until the early part of the present century. From 1817, the physicians of this country and of Europe have become familiar with what is now denominated the Asiatic cholera. Histories of this disease have been found extending back a couple of centuries. When the Madras Medical Board was called upon to report to the government all the facts that they could ascertain regarding its history, nature, and treatment, they discovered in their researches that a Dutch physician named Bontius had described a disorder which they recognised as identical with that they were familiar with in 1817; he having described it in 1629. Between that period and the date of their report, this Medical Board was able to discover occasional outbreaks of the same affection, but confining itself, in all this period of time, to the region where it was originally produced—in India—or spreading only short distances. In 1817, as most of you are already informed, it began its march westward; indeed, it began its march from the Delta of the Ganges in every direction—not westward only, but eastward, northward, and southward. It was not, however, until 1830 and 1831, that it fairly made its appearance in Europe; having, however, first reached Astrachan in 1832. In 1832 it appeared in this country; and from that time till the present, Europe and this country have been visited by four severe epidemics. The first here occurred in 1832; the disease beginning in Quebec and Montreal, within two days of the same time, the 8th of June, and reaching New York in the latter part of June, probably about the 24th, it was declared epidemic in this city on July 3d of that year. Again it appeared in 1834; an epidemic of no very great severity, compared with that which preceded and that which followed, but still an occasion on which a considerable number of lives were sacrificed. Again, in 1849, it made its appearance in this country; and then the mortality was great. Once more, in 1854, it occurred here, and spread pretty widely through the country; but produced less mortality than the preceding occasioned.

The interest which attaches to this subject to-day is, that the same disease has been prevailing anew in Europe, in Asia, and in Egypt; and fears are entertained that, with the opening spring or coming summer, it may again visit us. In view of this last fact (and with reference to the probabilities of this I shall make some remarks by and by), it has seemed to me worth while to take a general review of the history of this disease, to look up the opinions and experience of the past, and see if there is anything in such a survey that will enable us to meet the disease with more hopefulness when it comes again, if indeed it must come, and with a better understanding of our resources and duties in regard to it; and so I propose to present to you the results of this examination. It will at least save you a great deal of time and reading, and perhaps put you in a position to begin the conflict with it armed with a knowledge of most that is known of the disease at the present moment.* The mode in which I propose to treat the subject leads me, first, to present to you its pathological anatomy; you will appreciate the symptoms all the better for knowing what changes are coincident with them within the body.

With reference to what is to be found after death, one of the most striking things to be noticed is the appearance of the cadaver. The body of a person who has died of cholera presents peculiar appearances that would enable one at all familiar with the disease to recognise it at once. The features are thin; the surface, either in parts or throughout the whole extent of it, is of a bluish or slightly livid color; the fingers are thin, and at their extremities and palmar surfaces they are wrinkled, like the fingers of a washerwoman; there is a leaden paleness of the face; there is usually a ring, more or less distinct, of a blue or livid color about the eyes, and these organs are sunken; sometimes the tendons, particularly of the feet or of the wrists, and occasionally some of the tendons of the legs, stand out prominently, as if there were some unnatural contraction of the muscles.

There is something, too, in the mode in which the stiffening of the body occurs that is worthy of notice. You are all aware that the dead body becomes after a time stiffened, so that it is difficult to flex the joints; this is called the rigor mortis. This rigor mortis occurs in persons who have died of cholera, earlier than in most other diseases; and it is especially remarkable that it will in many instances occur before the natural heat has left the body, or is materially diminished; it has been known to occur when the temperature was as high as 100½°; it takes place often in forty minutes from the time of death, and is usually noticed to have occurred within the first two hours.

Again, in the dead body after cholera, there are certain strange movements of the muscles noticed. It is a very well known fact that after a sudden death, the muscular contractility is preserved for some time, and can be brought into exercise by proper stimulants. It is a common experiment upon the bodies of criminals who have been hanged, to apply electricity to make the muscles contract; and this kind of contraction can be continued for some hours after death, two or three in many instances; this fact shows you, at least, that the ability of these muscles to contract has not been lost at once, even though death of the body has occurred. So, after certain diseases, this power remains; and the muscles move the limbs, under the influence of irritation, in the reflex nervous system. The nerves then are not yet wholly dead. This has been observed in persons who have died of apoplexy; it was observed by Dr. Dowler in some who died rapidly of yellow fever; and it has been noticed in a few other instances. But after cholera it is of more frequent occurrence, and is more striking than in perhaps any other affection; as, for example, we have records of a great variety of movements of the hands and of the legs; the movements are almost always slow; the hand is often brought slowly up upon the breast and allowed to rest there; in one instance, recorded in the *Medical Gazette*, the dead person lifted both hands slowly upon the chest, brought them

* One of the richest repositories of information which I have consulted, is entitled "Reports on Epidemic Cholera, drawn up at the desire of the Cholera Committee of the Royal College of Physicians, by William Baly, M.D., and William W. Gull, M.D." From this book I have drawn much that will be found useful in these lectures. I make this general acknowledgment to avoid the inconvenience of frequent reference.

together, and clasped them as in the attitude of prayer. In another recorded instance, the eyes were slowly opened and turned downwards. In still another instance, pretty decided convulsive movements were noticed by a Russian physician; and in that instance, the movements were not of course so slow as in the others referred to. These movements are occasionally so marked as to lead to the impression that the person cannot be dead; but you will not understand that they occur in every instance.

Still another circumstance regarding the body: in persons who have died of cholera, usually at the time of death the temperature of the surface is below the normal standard, and it is a very common occurrence that the temperature of the body rises, after the breath has ceased, from a degree and a half to three degrees; and this apparent production of heat does not depend on the temperature of the atmosphere, notwithstanding the disease prevails most virulently in warm weather; it is observed in the mouth or in the axilla of the patient; it is observed particularly upon the surface by folding a portion of the skin over the bulb of a thermometer. Outspread portions of the body are apt to be cooler than such parts as are closed upon themselves, as the mouth and axilla. This elevated temperature was preserved so long in a case observed by Dr. Green, and recorded in one of the London journals, that he was induced to believe there was a lingering spark of vitality in the body, and had it surrounded with sawdust, hoping nature would find some other means of announcing lingering life; in the meantime he applied electricity and opened a vein, but after two days' trial he was induced to abandon the attempt; but during those two days the temperature had not greatly fallen, though that it had not, is to be ascribed in a great degree, doubtless, to the fact that it was cherished. This same increase in surface temperature after death has been observed in yellow fever, after puerperal fever, and after asphyxia; but its occurrence after cholera is so much more frequent and marked, that it makes it a prominent feature of the disease, and is worthy of particular mention. After most diseases which produce a fluid state of the blood, as seen at *post-mortem* examinations, the decomposition of the body takes place rapidly. Cholera seems to present an exception to this law. The purefaction process is not more rapid than after death by an acute inflammation.

Now, if we turn to the organs in the interior of the body, we shall find it a pretty elaborate study to notice all the changes that have taken place during the progress of the disease. Let us look first at the brain. Within the cranial cavity of those who die of Asiatic cholera, it is common to find a considerable amount of congestion in the vessels of the dura mater, in the great sinuses, and in the vessels of the pia mater; and not unfrequently the vessels that ramify through the substance of the brain are found to contain more than the usual or proper allowance of blood; and this is more particularly true of those persons in whom, among the later symptoms, was stupor or coma. It is not by any means in all the persons who die of this disease, that this congested state of the vessels is discovered; but in a considerable proportion, amounting to nearly one-half, it occurs in a greater or less degree. In a certain proportion, also, it is ascertained that serous effusions take place, chiefly in those persons who had passed into the typhoid state, or in whom, during the collapse, there was noticed somnolency or a considerable amount of coma. The effusion has been found in considerable quantity, and occasionally it has been observed to be stained with blood. The substance of the brain itself has not been found to have undergone any material change; it has sometimes been of a reddish hue, in bands and stripes occasionally; but this has not been regarded as a matter of much importance, inasmuch as other parts of the body have been similarly colored. This appearance is ascribed to the changes that have taken place in the blood. The spinal cord and medulla oblongata have been examined; but we are not prepared to say that they undergo any change that is peculiar to this disease, or necessary in the progress of it. Another part of the nervous system has attracted particular attention, because the prominent symptoms of cholera seem very readily to be referred to it—I mean the semilunar ganglion, and the ganglia that govern the circulation and secretions of the intestinal canal. Most observers who have paid particular attention to the pathological anatomy of cholera, have not failed to make explorations in this direction; and, so far as investigation has gone, they occasionally state that these parts were softened, or of unnaturally deep color, or were red, or had undergone some change that seemed to be at first view important. Still, the general summing up of the account stands thus: no special lesion has been discovered in these parts that has the character of constancy; nothing has been noticed that can be distinctly claimed as having any definite relation to the phenomena of cholera. This is the more interesting, as you will see by and by, because it seems almost necessary to refer many of the symptoms to disorder beginning here.

Then, if we turn to the alimentary canal, we shall find there very marked changes. It is upon this part of the body that the disease seems to expend its principal force; and after death we should naturally expect to find that this diseased action had left its mark; and so we do in certain of the cases. Begin, for example, with the mouth: it is discovered that a change has begun in the fauces; that the secreting follicles, in many instances, are elevated and reddened, and occasionally contain a puriform fluid; they are to be seen in this condition about the base of the tongue and upon the tonsils. The œsophagus has been examined, the lower portion of it, and sometimes its whole extent has been found denuded of its epithelial covering; at times it has been found vividly injected, more rarely covered by a whitish consistent exudation. At other times no material change is noticed Coming to the stomach, we find that in many instances, at least, there are changes of a most marked character; and yet in a considerable number of those who die of this disease, the mucous membrane is only observed to be pale. You will perhaps get a better idea of what actually takes place in this organ from some figures I have here, illustrating the various conditions. Here, for example, is a figure which represents two stomachs; one, you observe, is of rather a pale hue, yellowish, and studded all over with little elevations; the other is remarkably red—red by what is called punctated injection. Both these show conditions observed after cholera. In one the vascularity seems to be in considerable degree exhausted; in the other it still remains. In the second case, the organ was decidedly contracted, and red over the whole surface, but particularly upon the tops of the rugæ. From the first, you will get an idea of one of the most striking changes observed in the alimentary canal of persons who have died of this affection: it is in the enlargement and elevation of the solitary glands, which are seen standing out in groups, filled with a fluid material, the nature of which varies in different cases. These sacs are sometimes ruptured, leaving little pits in the membrane that appear as if they had been cut with a little punch. The sacs are analogous to the glands of Brunner in the intestinal

canal. You have not, perhaps, all become familiar with the fact that there is in the stomach a system of sacs resembling those associated with the lacteal system of the intestines. Here is another illustration; it is one of the plates of Pirigoff, showing a moderate amount of vascularity. You observe in this what you would hardly look for—the food remains entirely undigested in the stomach after vomiting has been very considerable; the paper attached states that the Russians eat mushrooms considerably during Lent, and in this case they had been eaten, but not digested. There is some punctate injection through the whole of the interior of this organ. Another plate by Pirigoff which I here show you, seems to imply that the stomach may be subject to diseased action far greater than that represented in either of the other two figures. Here are extensive spots of injection and ecchymosis, and upon those spots is to be seen a membranous exudation of the granular sort, analogous, when examined microscopically, to the exudation produced by diphtheria. This is a striking figure, and represents a rare condition; it is rare to find the inflammatory action reaching this point. In many cases the stomach scarcely shows any change. In general, the more protracted the disease, the more marked will be the evidences of lesion in this organ. Almost invariably, however, when the mucous membrane is examined with care, it will be found to have undergone a little increase in thickness; it will look at least a little watery and pale. In a considerable number of instances, where no other marked change is noticed, the mucous membrane has undergone a mammillonation. You will remember what this term means, from what I have already said in speaking of mucous inflammations—little flattened elevations that cover more or less of the surface, occurring in different parts of the organ in cholera; but in other affections generally found about the pylorus, and extending back towards the middle line of the stomach. These things show very clearly that there has been a pretty decided change in the circulation here, and that change is at least hyperæmia—probably an inflammatory hyperæmia.

On the mucous surface of the small intestines the lesions are analogous to those of the stomach. In many instances there is nothing which particularly attracts attention. The membrane is pale, or there is only slight increase of vascularity here and there. But even in such cases a careful examination will disclose some œdematous swelling of the valvulæ conniventes, and by the aid of a lens it may be seen that the solitary and Peyerian glands are enlarged. There is also extensive exfoliation of the epithelium. The more striking changes belong to the more advanced stages of the disease and the more protracted cases. They are arborescent injections, varying in extent from a few patches to large tracts of the mucous surface; ecchymosis of a dark brown, almost black color, always in patches, but often of some inches in extent; the solitary glands swollen by a fluid effusion within their sacs, so that they have attained the size of a large bird-shot, or they have been ruptured by the accummulated fluid leaving pits in the mucous surface; the Peyerian patches rendered distinctly visible, and often elevated by a similar condition of the individual glands; diphtheritic exudations in spots of limited extent, chiefly noticed in the lower parts of the ileum; granular matter infiltrated into the tissue of the mucous membrane, probably diphtheritic in character; the spots so affected, often recognisable by their whitish or yellow color; ulcers half an inch or more in extent, through the mucous membrane only, resulting equally from the ecchymotic effusions, and from the infiltration of granular matter into the tissue. All these lesions I will now try to make you familiar with by putting into your hands drawings, plates, and sections of dried cholera intestines, with some explanatory remarks.

In this first illustration, you observe that the mucous surface of the intestine is very red, irregularly red; and that the redness does not always entirely encircle the intestine; while in this dried specimen you will remark that the injection is arborescent and uniform throughout the length and circumference of the piece. The vascularity, in these cases is greatest in the lower part of the ileum; still the whole length of the intestine may be injected.

Here (second illustration), you may see that while there is vascular fulness enough, there are spots of considerable extent where all trace of vessels is lost; and yet these portions are of a very dark blood-color. Here the blood has escaped from its vessels, and is outspread in the tissues of the intestine. So, too, if you examine this piece of dried intestine, you will find portions of it almost black; and if you hold it between your eye and the light, you will notice that these dark portions are almost opaque, while other parts are very red, with vascular injection. (Several illustrations and specimens exhibited, including the plates of Cruveilhier, Lebert, and Pirigoff.)

In this piece of intestine, you may notice round, yellowish-white bodies grouped into forms like those of the Peyerian patches. They are the so-called glands which constitute those patches, unnaturally swollen. The solitary glands are not here visible; but in these plates you will find both varieties represented as very prominent. Perhaps the most common alteration in the intestine after the exfoliation of the epithelium, is the distension of these little saccular bodies with fluid, or the occurrence of the pits left by their rupture. That this swollen state is not the result of mere imbibition, may be inferred from the appearances represented in this figure (one of Pirigoff's plates). The intestine is sprinkled over with little whitish pin-head elevations, each one of which is a swollen solitary gland; and each one is surrounded by a little zone of lively injection or ecchymosis. The same inference will follow the examination of the contents of these distended sacs. You notice that few of them are transparent, but that they are either opaline or opaque. They look as if they were filled, or partly filled, with pus. Indeed, some observers have described their contents as pus. Most of them, however, are filled with a fluid which is loaded with granular matter. I have not examined these granules by tests, to ascertain whether they are composed of oily or protein material, and do not know that anybody has; but when we remember that the alkalinity of the intestinal fluids is lost, and that the bowels have, long before this diseased action is completed, been washed clean of all the fatty constituents of food, we can hardly find ground for supposing they can be composed of oil. If, then, these granules should be found to have their origin in the same action which produces the diphtheritic patches, it would confirm the opinion that the intestinal hyperæmia is in some sense inflammatory. When, just now, I spoke of the frequency of this lesion, I included in the remark not only that degree of enlargement which is distinctly visible, as in these several plates and specimens, but also that small amount of distension which will require the lens to make it apparent. Here is a figure (by Pirigoff), in which these bodies are shown as when magnified eight or ten diameters, and in some the fissures caused by their rupture are distinctly seen.

Now, I show you some illustrations of the exfoliating epithelium. The late Prof. Horner, of Philadelphia, was among the first who noticed this denuding of the mucous lining of the intestines in cholera. The epithe-

lium sometimes falls off in pretty large sheets, or is found only partially detached. Injected preparations from the cholera of one of the later epidemics have been prepared and mounted for microscopical examination by Dr. Neil, of Philadelphia, which show this process of exfoliation very perfectly. By the kindness of Dr. Neil I possess some of these preparations, which show that the exfoliation extends even to the villi.

Of the diphtheritic exudation, I here show you several examples. They belong to the later stages of cholera, and are often found in those who die in the typhoid period. They are usually patchy, and often are found on an injected or ecchymotic portion of the membrane.

Here you may notice some oval patches about half an inch wide and three-quarters of an inch in length, of a yellowish color, that distinguishes them from the injected membrane in which they are set. These are circumscribed spots of granular infiltration. The mucous membrane is undergoing the changes which naturally end in the ulcers of which I have spoken. In another plate which I here show you, the process of sloughing, after circumscribed ecchymosis, is represented. You notice that the dead mucous membrane is raised, and partly detached from the muscular layer, still retaining something of the blackened appearance which the ecchymosis has produced.

If we turn for a moment to the mesenteric glands, we shall find that in the disease which has so flooded the intestines, they have not wholly escaped. They are often more vascular than in their normal state, and frequently a little enlarged. This figure (Pirigoff) represents them greatly increased in size. They are not often seen so large as they are here represented. These glands are also subject to the same kind of granular infiltration as that which affects the intestine.

On the peritoneal surface of the intestine, little has been noticed. Pirigoff has made more of a study of this part than any other author I have consulted. He thinks in the beginning there is a good deal of vascularity in the sub-peritoneal tissue of the small intestines; and that, as the disease advances, it diminishes until it has passed through the several grades represented in the four figures of this plate. In general, the peritoneal surface is described as dry, and the vascularity is seen only indistinctly through the membrane. There has been described, also, on this peritoneal surface, a deposit of fine granular matter which will form into a sort of froth or lather, when moistened and rubbed with the finger. This peculiar exudation, however, has not been noticed by many of those who have studied the disease with most care.

In the large intestines we discover changes analogous to those observed in the small. Here is a figure to represent the vascularity that occurs in this disease. It is partly produced by blood effused, and partly by blood still in the vessels. In general, the whole of the large intestine is not found in the same condition; portions may be pale, and others reddened by ecchymosis, and others by vascular injection, generally of the arborescent rather than the punctated variety. The granular deposit I referred to as occurring in the stomach and small intestine, is noticed also in the large intestine; and where incorporated with the mucous surface, it is not uncommon to find portions sloughing away or rather ulcerating in consequence of the change already described. Here is an exudation upon the surface of the mucous membrane of the large intestine, which seems to be made up partly of mucous, and partly of a kind of fibrinous matter. The mucous membrane is not vascular, but has become pale. These matters are doubtless occasionally discharged by stool. You will not infer, from what I have now said, that you are to expect to find such marked lesions as these in all cases you may examine.

The condition of the liver of those who have died of cholera, we shall find is not uniform. In general, this organ is pale and exsanguinated; occasionally it is found to be moderately engorged with blood; but in the greater number of instances there seems no excess of blood, and no marked change. Pirigoff has found what has induced him to suppose that the liver undergoes occasional fatty degeneration in circumscribed and limited portions; and he has found also (I anticipate a little) an inflammatory action in the gall-bladder, with exudation of diphtheritic membrane. Both of these lesions are represented in this plate. But the changes in the liver seem not to be very important. The gall-bladder is generally found full of bile, and the bile is, for the most part, in appearance, healthy; occasionally it is of a darker hue than usual, occasionally greenish; and in rare instances—one in thirty or forty—no bile proper will be found in this receptacle, but a glairy fluid; and in one instance, reported by Pennock and Gerhard, purulent matter was found here—and that may correspond with the patchy exudation on the inner surface of the gall-bladder.

Reports of Hospitals.

NEW YORK HOSPITAL.

Case of Dissecting Aneurism of the Aorta, with Plugging of the Arteria Innominata, by a Portion of the Internal Coat of the Vessel, and Rupture of the Pericardial Sac.

Under the care of Dr. W. H. Draper.

The patient was a man forty years of age, and had always enjoyed good health. Until within the last five years he had led a very active life, and been exposed to considerable hardship. Five years ago he came to this city, and since that time his occupation has been confining and sedentary. His general health, however, appears to have been fair; and nothing in his history, previous to the morning of his admission to the hospital, indicated the existence of any disease of the heart or large vessels. About four days previous to his death, he said to some friends that he was much depressed, and apprehensive that he was going to die suddenly, as his father did. He gave no reason for this fear.

On the morning of the day of his death, he left his office to transact some business at one of the courts. While on his way thither, in company with a police officer, and while laboring under some degree of mental excitement, he suddenly fainted and fell into the arms of the officer. He did not lose his consciousness. He was conveyed immediately to the New York Hospital, and on his arrival, complained only of great exhaustion and a sense of "*coldness of the abdomen.*" He did not complain of pain or dyspnœa. Dr. Emerson, the house physician, examined him carefully soon after his admission. He discovered a short, rude, systolic murmur at the base of the heart. He observed that there was no radial pulse in the right arm; that the cervical veins were considerably enlarged; and that the face had a cyanotic hue. When I saw the patient late in the afternoon, his face was pallid, the pulse was regular—about 100 in the minute, and feeble; entirely absent in the arteries of the right arm and in the right carotid. The jugular veins were very much enlarged, though not pulsating; and the systolic murmur at the base of the heart was plainly recognisable. This murmur was more diffused than is ordinarily the case in simple obstructive disease of the

aortic valves, and the area of mediastinal dulness was considerably increased. From these symptoms, and from the history which the patient gave of his attack in the morning, it was suspected that there had been a rupture of an aortic aneurism, and that the progress of the hæmorrhage had in some way been temporarily arrested. The most absolute quiet was enjoined, much to the astonishment of the patient, who remarked that he then felt perfectly well, and would be able to attend to his business the next day. About an hour after this advice was given, the patient sat up in bed to take some nourishment, and while feeding himself, fell back suddenly and expired. The autopsy was made on the following day. On raising the sternum, the pericardium was found enormously distended with blood. The heart and the arch of the aorta were carefully removed. The blood which filled the pericardium weighed two pounds. The heart was hypertrophied, and there was a considerable dilatation of the left ventricle; the aortic valves were elongated by the slitting down of their attachments to the artery. The aorta for about four inches was dilated to double its normal diameter. The valves, as well as the coats of the vessels, were atheromatous. About four inches beyond the valves, there was a transverse cicatrix in the aorta about an inch in length. This cicatrix appeared to be the result of old arteritis. About half an inch beyond the valves there was a rupture of the internal coat of the vessel extending through its entire circumference; through this rupture the blood dissected its way between the internal and middle coats, and forced a passage into the proper channel of the artery through an opening in the cicatrix above mentioned. A portion of the free margin of the internal coat was forced into the arteria innominata, effectually plugging that vessel, and causing the loss of pulsation in its branches before described. Near the origin of the coronary artery a small rupture was found, extending through all the coats of the artery; and through this opening the blood found its way, and dissected the visceral pericardium around the origin of the aorta and over the right auricle for a space three inches in diameter. At the time of the patient's death, the visceral pericardium gave way at a point about opposite the rupture in the coats of the vessel just described, and the pericardial sac was instantly filled with blood.

In establishing a theory for the explanation of the lesions in this case, we must start, probably, with the cicatrix, which was evidently the result of an old arteritis. At that point there was a decided contraction of the vessel, and between it and the valves there was a corresponding dilatation. In consequence of this dilatation there must have been more or less insufficiency of the aortic valves, and consequent dilatation of the left ventricle. It seemed altogether probable that the rupture of the internal coat of the artery, and its subsequent dissection, took place at the time of the syncopal attack in the morning; and that the final rupture into the sac of the pericardium occurred at the instant of death.

Test for Rum.—Mix a little of the rum to be tested with about a third of its bulk of sulphuric acid, and allow the mixture to stand. If the rum is genuine, its peculiar odor remains after the liquid has cooled, and even after twenty-four hours' contact may still be distinguished. If, on the contrary, the rum is not genuine, contact with sulphuric acid promptly and entirely deprives it of all its aroma.—*Druggists' Circular.*

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Feb. 21, 1866.

Dr. James Anderson, President, in the Chair.

DISCUSSION ON CHOLERA.

Prof. J. T. Metcalfe opened the discussion with some remarks upon the Diagnosis of Cholera. He would assume that the *materies morbi* was specific in character, introduced into the system in some instances by the respiratory mucous membrane certainly, in others by the digestive tract, and operated more particularly upon the blood and ganglionic nervous system. Also that it was capable of very great multiplication, as in the so-called zymotic diseases. As yet, however, nothing was capable of demonstration. But, be its essence what it may, it certainly had a tendency to follow the great routes of travel, although he would not assert the doctrine of *personal contagion.* Considering incubation as an element in a choleraic problem, three days may be regarded as the usual period; although it is possible to be no more than six hours. Not quarantine, influence of season, adverse winds, great elevation above the sea-level, or any known atmospheric condition, has proved any barrier. An attack may be repeated in the person of a single individual, and with undiminished severity. It may successively appear, as in the town of Leith in the years 1832 and 1849, under the very same roof, within a few feet of the same spot. The first cases of any general epidemic appear at the outer commercial edge of the country invaded. The favoring influences are a temperature above 60° Fahrenheit; the Russian and Scandinavian epidemics are exceptions; the heat, filth, over-crowded huts, deficient nutriment, and impure snow-water, are sufficient causes in explanation of its prolongation into the winter. Dr. Snow has found the mortality three and a half times as great among those using dirty water as those more particular in this respect.

The three varieties of this disease, fatal inversely in the order mentioned, are:

1. Where the loss of the animal heat and impaired circulation show themselves slowly, and where the precursory diarrhœa has lasted several hours, or even days. This is the most frequent form.

2. Where the algid phenomena manifest themselves after a few characteristic discharges.

3. Where these phenomena are present from the first; vomiting and purging may be absent, but autopsies discover the primæ viæ filled with fluid.

The loss of animal heat is probably due to the anæmic condition of the lungs. Death may occur within a very limited time; in India, according to an observer, "hale, hearty men were cramped, collapsed, and dead within five minutes." Any debilitating cause is an unfavorable prognostic element.

The prophylactic measures to be adopted refer to the period before the approach of the pestilence, and the means necessary for adoption before the earlier stages have merged into the algid state. For the former we must depend on quarantine, and sanitary regulations of the most efficient nature. For the latter we must expect success only from the arrest of the painless diarrhœa.

The post-mortem appearances, though interesting, shed no ætiological or therapeutical light upon the disease.

Recovery may be prompt and uninterrupted, or it may be through tedious sequelæ of adynamic febrile

reaction resembling typhoid fever. This condition may end in death by coma, by thoracic complication, by dysentery, or by exhaustion.

Treatment.—To control the painless diarrhœa, recourse must be had to rest in bed, warmth to the body. Some one of the cordial astringents of which opium forms a part is usually sufficient, when conjoined with quiet, pure air, and proper diet. For the cramps, frictions of extremities, hypodermic injections of morphia, and anæsthetic inhalations may be essayed. For the vomiting, cracked ice, cool effervescent drinks, epigastric warmth, and counter-irritation, are to be employed. Here rapid vesication, followed by the application of morphia salts, has sometimes given relief. Cold water freely given, is not contra-indicated; since there is a chance that all will not be ejected in the frequent vomiting.

For the collapse, it is our custom to use cold water internally, warmth to the surface, and eschew the large doses of opium; since, with returning vitality, cumulative poisonous effects may be manifested. In the reaction and secondary fever, general principles of treatment come in for employment. In convalescence, the patient's diet must be carefully watched. In conclusion, our wish for thorough instruction is limited to the following questions:

How most surely shall we prevent the disease from existing pestilentially? and

How, in the event of its prevalence, can it be most successfully managed?

Dr. J. H. Griscom remarked that, in his opinion, there were two special influences ever at work in the causation and extension of this disease.

The one exists in a general atmospheric condition, the character and origin of which are as yet undetermined. The other is local in nature, origin, and manifestation. To make his meaning more apparent, and perhaps more forcible, he would let the atmospheric and terrene influences each severally represent a blade of "the shears of Fate." Together, and properly adjusted, they were effective, separate, and remote—comparatively weak for mischief. The terrene blade is not unfamiliar, for have we not continually present the emanations of undrained, overcrowded tenements, reeking with filth, unswept streets, noxious manufactories, and the thousand other nuisances of neglected cities? To demonstrate the extent and efficacy of these prolific generators of pestilence, he would merely advert to the fact, that of the 25,645 deaths occurring in the city in 1864, more than one-half, on analysis, should be attributed to the operation of the above-enumerated and similar causes. The localities of cholera are peculiar, its favoring circumstances well understood, its victims almost exclusively of a certain class, and these are all identical with those which are known to be especially prone to, and provocative of typhus fever. Why, on board of the emigrant ship, does this scourge avoid the cabin stairs, and seek the hatchway? The line of division is certainly not over-definite; but still the fact is notorious that the steerage acts the part of the germinating soil and hotbed for the growth of that most serious form of the malady, *ship-fever*. As with ships, so with cities.

In opposition to the prevalent idea that cold and frosty weather was inimical to the origin and progress of the choleraic poison, he would cite the following instances. Among the 1200 inhabitants of the village of Cambroc, not far from Coatbridge, in Scotland, who were chiefly workers in iron, the cholera appeared on the night of Dec. 31st, 1848, and continued to rage until the end of the succeeding February. The type of the disease was more severe than in any other locality known to the official reporter, Dr. Sutherland.

Out of the whole number, 1100 were attacked. This outburst of the disease, we are significantly informed, took place after the people had been drinking for several days.

The town of Hamilton is another case in point. Here the cholera prevailed from December 24th, 1848, to March 7th, 1849. In a population of 9000, there were 440 cases and 251 deaths.

This epidemic, substantially, says Dr. Sutherland, when speaking of its prevalence in Edinburgh and Leith, followed the identical track of the fevers by which those towns are scourged.

But in an epidemic district all do not perish. Local influences accordingly come in for a share of attention. These may be specified as follows:

Overcrowding, dampness, filth, want of ventilation and atmospheric pollution, proximity to graveyards, offensive sewers, pig-styes, &c.; narrow, closely built, and confined neighborhoods, bad water, &c.; a subsoil impregnated with organic matter from filthy streets, cesspools, &c.; imperfect sanitary works.

The city of Edinburgh, the first part of the United Kingdom attacked by cholera in 1849, was badly off, even in regard to the removable causes of disease; but the various nuisances were speedily abated through the vigorous action of the local authorities. As a result, the mortality was diminished about one-half below that of the epidemic in 1832; while in all those towns where equally effective measures had not been adopted, almost the exact reverse was the fact. As in our city, the cholera of 1832 in the mortality lists attained a total of 3513, and in 1849 to that of 5071, it is fair to presume that the wisdom of the Scotch was lost upon the American. He would adduce another still more instructive example within the compass of a small town, in proof of the value of preventive sanitary science.

In Taunton, whose population did not much exceed 16,000, were situated at one end of the town the workhouse, and at the other the county prison. In the workhouse the refuse was conducted by a sewer into a garden cesspool, which was uncovered until just before the cholera began. Here, in a place where no ventilation was provided, the ceiling only 8 feet 9 inches high, the water-closets opening into the wards or staircases, and no appliances to promote personal cleanliness, there were 276 inmates. The 3d of November, 1849, witnessed the first case passing into hopeless collapse in ten minutes; in two days 42 cases and 19 deaths occurred, and in one short week 60 were swept away.

In the county jail, each prisoner enjoyed in his cell 819 cubic feet of air, with ample ventilation besides, and every convenience for personal cleanliness; the last of which was strictly enforced. In consequence, there occurred of cholera and diarrhœa not a single case. He also called attention to the boys' and the girls' schools, where the inmates of the former escaped with a less mortality, because they gained more ventilation by their persistent onslaught upon the window-panes. Among the inhabitants at large, some cases of diarrhœa were noticed, but not one of cholera.

The travelling community are not altogether responsible for the introduction of cholera. It does not always appear first upon the borders of the city, at the wharves and docks, the places of direct commercial contact; on the contrary, it appeared in the very heart of our city among the class peculiarly susceptible to typhus fever; even here following an erratic course, and demonstrating the universality of the atmospheric element. In 1832, there were found centres similar in point of filth from which the disease simultaneously radiated. Dr. Buchanan details the circumstances under which the cholera first appeared in Nashville, Tenn., January 20th, 1849

The subsidence of a partial inundation of the lower part of the city left a few houses almost surrounded by water. In one of them three fatal cases occurred in the persons of three intemperate men, and with these began the epidemic. The most ignorant and indigent were the greatest sufferers. He also adduced Dr. McPheeter's testimony in regard to localities in St. Louis during the same period, in which instances are cited, showing the relationship of the disease to violated sanitary laws. The foreign poor population, who are the most notorious offenders against these laws, furnished the largest number of victims. The authorities of that city were so apathetic that mass meetings were held to force them, in language not to be misunderstood, to do their duty or resign. A committee of health, composed of private citizens, received the delegated power of the municipal authorities, who were too fearful of assuming responsibilities from motives of economy, and they did what the city authorities should long before have done.

According to the authority of Dr. Bell, the first case in Louisville, Ky., occurred May 1st, 1849, at a house located below the summit of the second bank of the river, in the immediate neighborhood of yards receiving the washings of the more elevated grounds above. This was the same place from which the pestilence started in 1832 and 1833.

Out of a family of nine persons, who undertook to lodge in two newly plastered rooms, twelve by fourteen feet in size, only one survived at the end of the fifth day. His life was despaired of, but having been removed to a hospital, he recovered slowly.

Dr. Bell also describes a locality where, in certain malarial portions of the city, the cholera made fearful ravages, but by promptly removing the causes this disease was checked. In one case, the citizens who labored diligently in the daytime to render the situation a healthful one, escaped the contagion, while those who, contrary to instructions, exposed themselves to the night air, died. Those localities which bore the brunt of the visitation in 1833, and were since redeemed, escaped in 1849 or '50, while those which were unimproved by any sanitary interference were again invaded.

In Sandusky, Ohio, nearly six per cent of the whole population fell victims. Here a mental influence operated, beyond a doubt; since, so great was the panic, that business was suspended, and the post-office closed.

In Buffalo, according to Dr. Flint, the epidemic of 1849 prevailed with the greatest virulence in the streets close to the canal, densely inhabited, abounding in poverty and vice; secondly, in that portion known as "the Hydraulics," where miasmatic influence was somewhat rife, and the population not likely to escape epidemics; and thirdly, in a certain section almost entirely appropriated by German laborers.

The history of the epidemic in New York during the same year proved that the filthy, overcrowded localities held out superior attractions.

He extolled the prudential anticipatory course adopted by the Philadelphia authorities in 1849, whereby a total of 6573 nuisances was abated within a year. Here the cholera was moderate in type and extent. The first outbreak occurred May 30th, on board of a filthy canal boat; it ceased as an epidemic on the 18th of August, although some sporadic cases were announced up to September 22d, and summed up an aggregate of 1022 deaths. In New York, during the same period, the mortality was 450 per cent. greater. Again is Philadelphia leading the van.

The latter city possesses another hygienic advantage in the fact that, with a population of 100,000 less, she has 30,000 houses more than New York.

The case of Baltimore, where the most vigorous measures were adopted in the matter of purification, may also be cited in corroboration of our views. Here the cases were so mild that scarcely any alarm was created.

The communication of the U. S. Legation in Turkey, addressed to the Hon. W. H. Seward, at Washington, urging the most rigid quarantine regulations, has reawakened attention to this subject. And yet, according to the admissions of the accompanying newspaper, the notoriously rigid quarantines of the East have failed utterly to prevent the spread of the disease. Dr. E. M. Snow, of Providence, proved the futility of the absolute quarantine there in 1832 to prevent the introduction of the disease: "but the internal sanitary measures were so effectual, that the cholera did not become epidemic there in that season, and but few cases occurred."

Dr. Worms, physician in chief of the Military Hospital of Gros-Caillon, in an essay read before the *Academie de Médecine* of Paris, says that he has succeeded in materially ameliorating the condition of the patients by the use of *mineral lemonade* (giving them a double dose of acid), to the exclusion of all other medicines. The doctor had tried this method more thoroughly in the choleraic visitation of 1853 and 1854 than in that of 1849, with proportionately more gratifying results. "Two, three, or at most four grammes of sulphuric acid," continues our author, "with a thousand grammes of water, or a mucilaginous vehicle with one hundred and fifty grammes of simple or raspberry syrup, makes a drink as agreeable and innocuous as ordinary lemonade, and furnishes at the same time a medicine cheap, easy of preparation, and everywhere accessible.

"In cases of prodromic diarrhœa, and, according to the greater or less gravity of the case, I add three four, or at most five grammes of concentrated sulphuric acid to a kilogramme of a sweetened decoction of salep. A glassful every hour is to be taken, and four of them will seldom be found necessary."

The use of white wines, or of champagne, during an epidemic is permitted; but beer, brandy, and alkaline mineral waters proscribed.

In confirmed cholera, Dr. Worms enjoins the most complete repose, administers every half hour a glass of the lemonade, of five to ten *grammes* of the acid to a *litre;* taking the moment immediately after vomiting. Shampooing is practised only during the cramps; and wine with ice is used at discretion.

The lemonade, according to our authority, though it suspends the alvine evacuations, tends to promote the vomiting; but this he looks upon as indicative of a happy termination.

Dr. Griscom stated in explanation that a gramme was about 15 1-3 grammes, Troy measure; that a thousand grammes equalled 2 lb. 8 oz. 1 dr. and 4 grs. Troy; and a litre a fraction over two pints.

Asiatic Cholera in Virginia.—"It is a noteworthy and astonishing fact," says the *Lancet*, "that during the forty years in which this scourge has afflicted the earth, no case of Asiatic cholera has ever occurred in the basin of country embracing the mineral springs of Virginia."

Death of Professor Shuh.—The Vienna Journals announce the death of Professor Shuh, which took place Dec. 22d, from an attack of virulent typhus.

Horse-Flesh as Food.—Markets for the sale of horse-flesh have been officially established at Paris, Vienna, Stockholm, and Copenhagen.

Progress of Medical Science.

The Temperature of the Body as a Means of Diagnosis in Phthisis.—Prof. Sidney Ringer, of London, in a work recently published on this subject, advances the following propositions:—1. There is probably a continued elevation of the body in all cases in which a deposition of tubercle is taking place in any of its organs. 2. This elevation of temperature is probably due either to the general condition of the body (tuberculosis) or to the deposition of tubercle in its various organs (tuberculization). 3. This elevation is probably due to the general condition (tuberculosis) rather than to the deposition of the tubercle (tuberculization). 4. The temperature may be taken as a measure of the amount of the tuberculosis and tuberculization, and any fluctuations in the temperature indicate corresponding fluctuations in the severity of the disease. 5. The temperature is a more accurate indication of the amount of tuberculosis and tuberculization than either the physical signs or the symptoms. 6. By means of the temperature we can diagnose tuberculosis and tuberculization long before the physical signs and symptoms are sufficient to justify such a diagnosis. 7. By means of the temperature we can diagnose tuberculosis, even when during the whole course of the disease there are no physical signs indicative of tubercular deposit in any of the organs of the body, and in which cases the symptoms (apart from the temperature) are inadequate to enable us to arrive at such a diagnosis. 8. It is probable that by means of the temperature we can conclude that the deposition of tubercle has ceased, and that any physical signs that are present are due to obsolescent tubercle and the chronic thickening of the lung-tissue between the tubercular deposit. 9. It is probable, though farther observations on this point are necessary, that the temperature of the body affords a means by which we can diagnose between diseases in which the symptoms and physical signs are either too scanty or too much alike to enable us to decide between them.

Iodine in the Treatment of Uterine Leucorrhœa.—"We have lately observed a plan," says the *Lancet*, "which is being pursued by Dr. Murray at the Great Northern Hospital, and which promises to be a very useful addition to our means of treatment in this very troublesome condition. Dr. Murray first ascertains by means of the speculum, that the discharge proceeds from within the uterus. He then introduces a small short-haired brush (much like that used for washing phials), by a screw-like motion, so that the thick phlegm-like layer on the uterine wall is swept off with every turn of the brush. When this reaches the fundus, he steadily withdraws it, charged as it is with the mucous deposit. Its place is then taken by a gum-elastic catheter with several apertures, through which is injected a lotion consisting of one part of the compound tincture of iodine to two parts of water. The uterine wall is thoroughly washed with this." Dr. Murray, after numerous trials, is well satisfied with the success which he has had.

Balsam Peru in Itch.—Dr. Koch, of Gaildorf, speaks very highly of the use of balsam of Peru as a remedy in itch; a cure generally results in eight days. It can be used on the most tender skin.—(*Wurtemb. Corresp. Bl.*, 1864, 41). *Viertel-Jahrschrift.*

For Chronic Inflammation of the Glands of a Tuberculous, Scrofulous, Syphilitic, or Anœmic Character, which have not yet advanced to softening of the gland or reddening of the skin, Prof. Sigmund recommends a mixture of Tinc. iodinii and tinc. gallæ, equal parts; or where the skin is very tender, two parts of the latter to one of the former. This may be painted on two or three times daily; and five minutes after the application cold compresses may be applied if necessary. If the outer skin becomes too thick by frequent use of the remedy, the local use of lard is the simplest treatment. The tincture is said to be very rapidly absorbed, and after four or five applications it may be found in the urine or tears.—(*Wien. Med. Wochenschrift*, 1864, p. 49.)—*Prag. Viertel-Jahrschrift, Jany.* 1866.

Ox-gall for tœnia is recommended by Löwenthal, of Berlin. A tablespoonful of a mixture of two drachms of inspissated ox-gall and four oz. of camomile tea, or a teaspoonful of fresh ox-gall in a half oz. of cam. tea, to be taken morning and evening.—(*Prcuss. Ver. Zeitg.*, 1863, p. 16.)

The Treatment of Diabetes by Tinc. of Iodine was tried by Beranger Ferand, in two cases, with partially favorable results. 5–10–20 drops of the French tincture were used in 100 gram. of pure water, about ten minutes before meals. After its use a diminution of specific gravity and of the sugar was regularly observed. In one case, in eight days the specific gravity fell from 1.028 to 1.022; the sugar from 6.80 grm. to 2.50 grm. As soon as symptoms of iodism (diarrhœa, salivation, frequent blowing of the nose) appeared, the treatment was stopped; and on their subsidence, the specific gravity and sugar again increased. In two other cases the same gentleman used *inhalation of oxygen*, as recommended by Demarquez. At first twenty litres of oxygen with a like quantity of common air; afterwards the same amount of *pure oxygen* was inhaled morning and evening. Under these inhalations the thickness of the urine and the amount of sugar contained diminished rapidly, while at the same time the patient experienced great relief by the decrease of the tormenting thirst. B. F. does not think this treatment will *cure* diabetes, but believes it to be of great benefit.—(*Bull. Gen. de Ther.*, 1865).—*Viertel-Jahrschrift.*

Deodorization and Disinfection.—Dr. T. H. Barker, in a lengthy and interesting article (Hastings Prize Essay, for 1865), published in the *British Medical Journal* (January, 1866), arrives at the following conclusions: For the sick room, free ventilation when it can be secured, together with an even temperature, is all that can be required. For rapid deodorization and disinfection, chlorine is the best agent known. For steady and continuous effect, ozone is the best agent known. In the absence of ozone, iodine, exposed in the solid form to the air, is best. For the deodorisation and disinfection of solid bodies that cannot be destroyed, a mixture of powdered chloride of zinc with sawdust is best. After this, a mixture of carbolic acid and sawdust, ranks next in order; and, following on that, is wood ashes. For the deodorisation and disinfection of infected articles of clothing, etc., exposure to heat at 212° Fahr. is the only true method. For the deodorisation and disinfection of substances that may be destroyed, heat to destruction is the true method.

The Effects of Chlorine upon Vaccine Virus.—Dr. J. P. Loines, of N. Y., as the result of a series of experiments, has come to the conclusion that chlorine, in quantity sufficient to be irrespirable, has no effect upon the infecting property of the vaccine crust; and, reasoning from this analogy, is of the opinion that the same is the case with the poison of variola.

THE METROPOLITAN HEALTH BILL.

THE earnest desire of the medical profession of this city, and of the community at large, has at length been gratified by the actual passage of a bill for the protection of the health and life of the community. The urgent want for such provisions as are now embodied in the Metropolitan Health Bill has so long been felt, and so many measures have been taken by one party and another to effect the grand object, and the failures in their accomplishment have been so numerous, that it is really a matter of surprise, even to those who were reasonably sanguine in the matter, that we now have a law which, by the comprehensiveness of its scope and the liberality of its design, is well calculated to meet all the requirements of the case. It is true that the present bill is nothing more than the modification of the original one; but, after all, the alterations which have been made can have no direct tendency, as far as we can see, in interfering with its usefulness. The length of the bill forbids us giving our readers more than a mere synopsis of its provisions.

It creates a Metropolitan Health District, which has the same boundaries as the Metropolitan Police District. This district is in charge of a Board of Health, consisting of four Police Commissioners, the Health Officer of the port, and four Sanitary Commissioners—three of whom must be physicians, and one a resident of Brooklyn. The four Sanitary Commissioners shall hold office "respectively for the terms following—namely, one for one year, one for two years, one for three years, and one for four years; and until their successors shall be appointed and qualified." The term of office of each of the Commissioners, "after the expiration of the terms aforesaid, shall be four years."

The Board is to elect its own officers, and its President shall have all the power and authority given to the "City Inspector, in the six hundred and forty-sixth chapter of the laws of 1865 (passed May 1, 1865), in respect to the making, awarding, or executing of a contract or contracts for street-cleaning, or any matter thereto pertaining."

The Sanitary Commissioners are to receive a salary of two thousand five hundred dollars per annum, and the Health Officer and Police Commissioners five hundred dollars per annum, as members of the Board; and all are forbidden to accept any other political or municipal office, or any nomination for such office, during their terms. Any member may be removed by the Governor, under the law relating to the removal of sheriffs.

The Board of Health has authority to appoint a Sanitary Superintendent, who must be an "experienced and skilful physician," and who shall, under its direction, "exercise a practical supervision" over all the agents of the Board, except the police. This Sanitary Superintendent is to receive a salary not exceeding five thousand dollars, and is to have two assistants at three thousand five hundred dollars each, one of whom must reside in Brooklyn, and perform the duties of Sanitary Superintendent for that city. He is to report in writing to the Board weekly, or oftener, on the work of his subordinates, and the sanitary condition of the district.

There are, further, to be appointed by the Board, fifteen district inspectors, ten of whom must be skilful physicians, acquainted with the districts in which they serve; and each of these is to report in writing twice each week, "stating what duties he has performed, and where he has performed them, and also such facts as have come to his knowledge connected with the purposes of this act, as are deemed worthy the attention of said Board, or as its regulations may require of him."

The amount of authority vested in the Board is immense; absorbing and exercising as it does exclusively all the powers and duties in regard to the sanitary management of this city and Brooklyn which have heretofore been exercised by various individuals and bodies under a number of laws and ordinances. Peremptory power is given it to remove nuisances of every description and kind; to cause the cleansing and purification of alleys, streets, sewers, tenement-houses, and watercraft, and to take such other steps as may be necessary to insure the safety from disease of those persons residing in such vicinities.

In cases of impending pestilence, or in the event of the presence of a pestilence, it shall be the duty of said Board "to take such measures, to do and order, and cause to be done, such acts, and to make such expenditures (beyond those duly estimated for or provided) for the preservation of the public health, as it may in good faith declare the public safety and health to demand, and the Governor of the State shall also, in writing, approve. But the exercise of this extraordinary power shall also, so far as it involves such excessive expenditures, require the written assent of at least six members of the Board."

The Board is to keep a register of births and deaths; to inspect weights and measures; to coöperate with the

Quarantine Commissioners; to communicate important sanitary information to the health authorities of other parts of the State; to charge no fees; to enforce the laws relating to the sale of unwholesome food and deleterious drugs; to attend to vaccination, and other preventive sanitary measures; to report annually to the Governor of the State the sanitary condition of the district, together with the laws and regulations of the Board, and its expenditures; and on or before the 10th of May in each year, to publish a "Code of Health Ordinances," violations of which are to be punished by the courts by fine.

A very important and useful feature is the keeping open of a public complaint-book, in which citizens may notify the Commissioners of any nuisances which require to be abated. By this provision the Board will be enabled in a very direct manner to take prompt cognisance of many minor matters which might, perhaps, escape the vigilance of the subordinate officers. A sanitary engineer is to be employed, who shall survey and examine all premises and localities, and make such reports to the Board as it may order. Ample provisions are made for the employment of the necessary number of clerks and subordinates.

Since the passage of this act, on the 19th of February, the Sanitary Commissioners have been appointed by the Governor, and confirmed by the Senate. The gentlemen composing the Board have been well chosen, and, individually and collectively, are such as have the entire confidence of the profession and the community. They have already organized, have had several meetings, and have fairly initiated the great work which is before them.

Our profession is well represented in the Board by Drs. W. Parker, J. O. Stone, James Crane, of Brooklyn, the Sanitary Commissioners; Dr. John Swinburne, the Health Officer, Dr. E. Harris, the Registrar of Records, and Dr. E.B. Dalton, the Sanitary Superintendent. All of these gentlemen are acknowledged to be well qualified for their respective places. With the ample provisions of the bill, and the efficient aid which they will receive from the Police Department, and from the other members composing the Board, we have a right to expect such an enforcement of sanitary regulations as will tend to make New York a model city for cleanliness, and one of the healthiest upon the globe.

The Lecture of Prof. Clark on Cholera, which is the first of a course upon that disease which will appear in our columns, will, we doubt not, be read with great interest by the profession at large. The entire course has been phonographically reported; and each lecture will be, as this has been, revised by Dr. Clark before its publication. This insures an accuracy in the statements of the Professor which the great importance of the subject of which he treats demands.

FIFTY-NINTH ANNUAL MEETING OF THE NEW YORK STATE MEDICAL SOCIETY.

Tuesday, Feb. 6, 1866.

The New York State Medical Society held its fifty-ninth annual session in the City Hall, at Albany, N. Y. The meeting was promptly organized. The aggregate attendance amounted to nearly 200 representatives and invited guests.

The President, Dr. Henry W. Dean, of Rochester, delivered the inaugural address, for which he received the thanks of the Society.

The Chair announced the following Standing Committees:

On Business—Dr. White, of N. Y.; Dr. Vanderpoel, of Albany; Dr. Hall, of Auburn.

On Reception—Drs. March, Townsend, and Quakenbush.

On Credentials—Drs. Corliss, Saunders, and Bissell.

The Committee of Three, to whom was referred the consideration of the suggestions contained in the inaugural address, were by appointment as follows: Drs. James Kennedy, E. L. Beadle, and C. Green.

Several delegates from other State Societies, and such members of the Legislature as might belong to the medical profession, were invited to seats in the Convention.

Dr. Henry D Noyes, of New York, then read a very interesting illustrated paper upon "Cases in Ophthalmic Surgery." The following presentations were also made: "A Memoir of Dr. Wm. Bay of Albany," and the report of a case of "Progressive Locomotory Ataxia," by Dr. S. O. Vanderpoel. A paper on "Hospital Gangrene," by Dr. Walter Kempster of Syracuse. Another on "Inflammation of the Kidneys and Suppression of the Urine," by Dr. Charles Barrows of Clinton. A paper entitled "Tabulated Obstetrical Statistics," by P. O. Williams, was also presented by deputy; likewise a monograph upon "Gunshot Wound in Substance of the Liver." An essay on "Tetanus," by B. D. Carpenter of Staten Island, and on "Congenital Hypertrophy of the Tongue," by Alfred Bolton of Homer, constituted the remainder. The following additional Committees were appointed by the Chair:

On Nominations—Drs. Squibb, Parker, Seymour, Chamberlayne, Richardson, Cook, Lyman, and Langworthy.

On Resolutions—expressive of regard for the memory of Dr. Thomas W. Blatchford, of Troy, N. Y.—Drs. Brinsmade, Bissell, and Townsend.

The Society re-assembled after recess at 3 P.M.

After the reading of Dr. Kempster's paper, and the registration of some additional members, the subject of the New York Health Bill was introduced by Dr. James Kennedy in the following resolutions:

"*Resolved*, That the Medical Society of the State of New York, now in Convention, in view of the importance of the bill now before the Legislature, and which has passed the Senate, known as the 'New York Health Bill,' very respectfully asks the Assembly to concur with the Senate, in order that the said bill may become a law.

"*Resolved*, That a copy of the above resolution be sent to the Speaker of the Assembly."

Dr. B. P. Staats, in view of the fact that the bill had undergone considerable emendation at the hands of the Senate, favored the reference of the matter to a Committee, which, as subsequently constituted, consisted of the following gentlemen, who were instructed to report on the morrow:—Drs. Willard Parker, Stephen Smith, James Kennedy, C. R. Agnew, and J. T. Williams. A desultory debate on the bill then took place, but gave

way to the reading of Dr. Lawrence McKay's paper on "The Gingival Margin as a Diagnostic Sign." This was followed by Dr. Squibb's "Appeal for the Materia Medica."

The resolution accompanying the latter gentleman's effort, and another presenting both to the different State Medical Societies, with request that they take similar action, were, on motion of Dr. Lewis A. Sayre, adopted. The Treasurer's report was referred to the usual committee for examination.

The following papers, read by title by Dr. Thos C. Finnell, of New York, were referred by the Business Committee to the Committee of Publication: "Obituary of A. B. Conant, by E. R. Peaslee, M.D.;" "Eulogium on Prof. Chandler Robbins Gilman, M.D., by Wm. C. Roberts, M.D."

"An Inquiry relative to the Subject of the Formation and Expectoration of Bronchial Casts, accompanied by the History of an Illustrative Case, by Stephen Rogers, M.D."

"Embalming, as practised in Ancient and Modern Times, its Applicability to the Preservation of Anatomical Specimens, by James E. Steel, M.D."

Drs. Alden March, L. A. Sayre, and John Swinburne, strongly endorsed the paper on "Excision of the Shaft of the Humerus," read by Dr. William Gilfillan of Brooklyn.

Dr. Sayre next presented a "Case of Broken Neck."

Dr. A. B. Shipman, of Syracuse, pronounced a fitting eulogium upon the character of the late Dr. William Taylor of Manlius, and moved the appointment of a Committee of Three to draft suitable resolutions. Adopted; and Drs. Shipman, Chamberlayne, and Cook were appointed.

Dr. Ezra M. Hunt, of New Jersey, made some very appropriate remarks, returning thanks to the Society for the courtesy extended to the delegates from New Jersey.

Adjourned until Wednesday at 9½ A.M.

WEDNESDAY, Feb. 7, 1866.

The President, Dr. H. W. Dean, in the Chair. After the transaction of the usual business routine, and the disposition of certain memorials, Dr. Williams, the chairman of the Committee on Conference with the Legislature regarding the Health Bill, asked further time.

Drs. H. S. Crandall, of Swordsville, and J. C. Hutchison, of Brooklyn, were appointed to fill the vacancies occasioned by the resignations of Drs. Agnew and Parker.

Drs. Peaslee, Hutchison, and Husted were appointed a Committee to draft resolutions expressive of their feelings with regard to the late honorary member, Dr. Valentine Mott.

Dr. F. D. Lente, of Cold Spring, explained the use of a new instrument for inhaling sulphuric ether.

Dr. Edward H. Parker presented a paper upon "The Uses of Chloroform and Ether."

The same gentleman offered a resolution enjoining economy in the use of illustrations, and substituting woodcuts for lithographs whenever practicable in their annual issues. Dr. Vanderpoel's motion of reference to the Publishing Committee, after some discussion, finally prevailed.

The invitations of Surgeon-General James E. Pomfret and Governor Fenton were, on motion of Dr. Williams, accepted.

Dr Gurdon Buck, of New York, read a paper illustrative of cases, one of "Destruction of the Body of the Lower Jaw, with extensive disfigurement of the Face from a Shell Wound." The particulars of two other cases of deformity were also given.

Dr. E. R. Peaslee, of New York, followed with a paper upon "Retroflexion of the Unimpregnated Uterus."

The Business Committee recommended the succeeding papers to be read by title merely, and referred to the Committee on Publication:—

"On Adaptability of the Hospital and Cottage plan to the treatment and management of the Insane Poor, as illustrated by the Colony of Fitz-James, at Clermont, in France, by Charles A. Lee, M.D."

Also, "An Inquiry into the Mode of Propagation of Cholera, with Facts and Reasons in favor of the Theory of its Transmission by Choleraic Stools, and in no other manner, with Suggestions in regard to the proper preventive Measures to be used in case the Disease should again appear among us, by Charles A. Lee, M.D."

Also, a case of "Acute Enteritis, treated by B. G. McCabe, M.D., Monticello, Sullivan County."

Also, a "Memorial of the late Dr. Simeon Snow, of Montgomery County."

A paper on "Biliary Calculi" was read by Dr. Alden March.

The Treasurer's report, on examination by the proper committee, was found correct. Recess until 3 P.M.

AFTERNOON SESSION.

After the transaction of certain unimportant business, the Committee on the Inaugural Address of the President reported substantially as follows:—That the President designate some one from among the many personal friends of the late Dr. S. D. Willard to prepare his memorial in time for the next volume of the Transactions; that for the apathy manifested in the matter of county society organizations, the Committee can suggest no remedy but the sterling good sense of the parties concerned; that they endorse the proposed representation on the *pro rata* medical population basis; and that the State Society should constitute the Court of Appeals for all differences or questions of discipline originating in the County Societies.

On motion, the report was accepted and committee discharged.

Several delegates from sister State Societies expressed their gratification at the cordial manner of their reception.

Dr. Corliss gave a very interesting account of his visits to the Connecticut and Massachusetts State Medical Societies.

Dr. Sayre offered the following:

"*Resolved*, That the Secretary inform the delegates to the different State Societies of the time of their several meetings." Adopted.

Dr. Williams, from Committee on Health Bill, reported, by resolution, as follows:

"*Resolved*, That the State Medical Society, now in session, does hereby earnestly urge the Assembly to pass, at the earliest day, a Health bill which shall retain the grand sanitary provisions and regulations contained in the bill which recently passed the Senate; as to the mode or manner of appointing the Commissioners to execute said law, the Society offers no suggestions, leaving this wholly to the wisdom of the Legislature.

"*Resolved*, That a copy of the above resolution be sent to the Speaker of the Assembly at the earliest practicable moment." Adopted.

Dr. Edward Duffy, of Albany, presented a paper, entitled "Potassa Fusa as a Local Application to *Carbuncular* Inflammations, Whitlows, and in *Sympathetic Bubo*." Referred to Publication Committee.

Dr. Duffy also presented a paper "On the *Method of making Exhalation of different Odors visible*."

Dr. Crandall offered the following, which was adopted:

"*Resolved*, That in accordance with the suggestions of

the Committee on the Inaugural Address, the President is hereby authorized to appoint one or more members of this Society, residing in Albany, to prepare a suitable memorial of the late Secretary, Sylvester D. Willard, and that the same be published in the forthcoming Transactions."

Dr. J. H. Curry offered the following:

"*Whereas*, This Society wish to express further its appreciation of the life and character of S. D. Willard, M.D., late Secretary of this Society, and to show, in some measure, their sympathy with his numerous friends not connected with the profession; therefore,

"*Resolved*, That the members of this Society do request the biographer of the late Dr. Willard to issue five hundred extra copies of said biography, together with the steel plate of his likeness, and that the members of this Society will pay each the sum of $— to defray the expenses of the same."

The Chair appointed Drs. Townsend, Hun, and Bailey a committee to collect subscriptions for the above object.

Dr. L. A. Sayre, in behalf of the Committee on application to the Legislature regarding laws for Medical Societies, reported the draft of a bill. Dr. Govan's motion that the Legislature be requested to make the same a law, was adopted.

Drs. March and Quackenbush were appointed a committee of arrangements to procure more convenient accommodations for holding future meetings of the Society.

The following papers, read by title, were referred to Committee on Publication:—

"Continuation of the Essay on Compound Human Monsters," by Dr. Fisher.

"Sanitary Condition of Fish-Alley and Surroundings," by Dr. Wm. F. Thoms.

Dr. John P. Gray read a paper on "Incomplete Progressive Paralysis."

Dr. George T. Stevens read a paper on "Excisions in Cases of Gunshot Wounds."

Dr. Henry S. Downs described a case of hydrocephalus.

The Committee on resolutions in memory of the late Dr. Blatchford, of Troy, reported through Dr. Brinsmade, with the request that Dr. Stephen Wicks, of Orange, N. J., prepare the obituary for the next volume of the Transactions. Adopted.

Adjourned to hear the Annual Presidential Address, at 8 o'clock, in the Assembly Chamber.

EVENING SESSION.

Dr. Hutchison, Vice-President, in chair.

The Annual Address by Dr. H. W. Dean was delivered, followed by the tender of a vote of thanks to the orator. Adjourned to 9 o'clock, A.M.

THURSDAY, Feb. 8, 1866.

The Society re-convened at half-past 9 A.M.

After the usual routine business, Dr. Hutchison moved that the committee appointed to draft suitable resolutions expressing the sense of the Society relative to the death of Dr. Mott, be authorized to prepare such resolutions as they may think proper, and send them to the Committee on Publication, to be published in the Transactions of the Society. Adopted.

Resolutions to the memory of Dr. Wm. Taylor, of Manlius, Onondaga county, presented by Dr. Shipman, of the Special Committee, were adopted.

Dr. Bissell offered a series of resolutions, of which the following were the most important:—

"*Resolved*, That this Society concur in the views taken and the recommendations made by the 'Council of Hygiene and Public Health' of the citizens of New York, to protect the people of that city against the introduction and spreading of Asiatic cholera; the causes which will produce epidemic cholera, and the hygienic measures which will prevent its deadly march in that city, will produce like effects in every other part of the State.

"*Resolved*, That the Council of Hygiene and Public Health of said city are entitled to the thanks of the medical profession and people of the State, for their full and able report on Epidemic Cholera, adopted Nov. 14th, 1865, and that a copy of the same should at once be placed in the hands of all Common Councils, town authorities, and Boards of Health, within the State limits, for their direction and guidance in the case of preventive measures, before the cholera shall visit their localities." Adopted.

Dr. A. N. Bell moved that the same acknowledgments be tendered to Drs. L. A. Sayre, William Murphy, and J. Swinburne, and to the Mayor of New York, for their efforts to exclude and prevent cholera, as published in a pamphlet for public distribution, under date of November, 1865, and that this pamphlet be distributed in the same manner as that of the report of the Citizens' Association. Adopted.

Dr. Wheeler, of Massachusetts, made some very interesting remarks expressive of his appreciation of the Society. He also illustrated a case of "Urinary Calculi."

Dr. E. H. Parker reported with regret that there were no competitions for the "Merritt Cash Prize Essay" on the "Pathology and Treatment of Chronic Diarrhœa, contracted in Camps and Malarious Regions;" also that for the Brinsmade Prize, for the best essay on "Medical and Vital Statistics," but one paper had been presented, and inasmuch as this did not comply with the rules specially laid down by the founder of the prize, nor fill the scope of requirements exacted by him, the Committee did not feel themselves authorized to receive the essay, and could, consequently, express no opinion upon its merits.

The Committee closed their report with a tribute to the memory of their lamented colleague, the late Dr. Thomas W. Blatchford.

Dr. Vanderpoel moved that the same Committee be continued, and that the subject of essays be referred back to that Committee, for action according to their judgment. Carried.

Dr. Squibb, from the Committee on Nominations, recommended the following:

For President—Joseph C. Hutchison, M.D., of Brooklyn.

For Vice-President—Julien T. Williams, M.D., of Dunkirk, Chatauque Co.

For Secretary—William H. Bailey, M.D., of Albany.

For Treasurer—J. V. P. Quackenbush, M.D., of Albany.

FOR CENSORS.

Southern District—Oliver White, of New York; Dewitt C. Enos, of Brooklyn; Samuel A. Purdy, of New York.

Eastern District—B. P. Staats, of Albany; T. C. Brinsmade, of Troy; P. McNaughton, of Albany.

Middle District—M. M. Bagg, of Oneida Co.; C. B. Coventry, of Oneida Co.; A. F. Doolittle, of Herkimer Co.

Western District—Alexander Thompson, of Cayuga Co.; C. M. Crandall, of Allegany Co.; Edward Hall, of Cayuga Co.

The usual Committees were likewise provided for, and the report, as a whole, unanimously adopted.

Dr. Squibb offered the following, which was adopted:

"*Whereas*, There is reason to suppose that some persons are admitted to the courtesies of this Society, and to a place upon the register, who may not be properly entitled to such a position; therefore,

"*Resolved*, That the Committee on Credentials and Reception be instructed by the Society to be careful in their scrutiny of all the names who may be admitted or invited to the floor of the Society, and to so control the register that no improper names obtain access to it; also, that this Society do not act on this subject independent of the Committee's action."

Dr. Beadle moved that the Committee on Credentials have power to erase the name of any person registered as a delegate from any society or institution not entitled to representation in this Society. Adopted.

Dr. G. J. Fisher, delegate to the Medical Society of the State of New Jersey, presented a report, which was accepted.

Dr. White moved that the thanks of the Society be tendered to our out-going President, Dr. Dean, for the efficient, courteous, and dignified manner in which he has discharged his duties, notwithstanding the embarrassing circumstances attending his appointment. Adopted.

Dr. Edward Duffey, of Albany, at the request of the President, then addressed the Society, giving his experience of cholera in St. Louis in 1848–49–50 (while practising in that city), and in regard to the analysis of and experiments on Asiatic cholera dejections, both in man and the lower order of animals, and the disinfection of same by the limited use of chlorics and the total destruction or burning up of the dejections by the sulphates; and the incontestable and conclusive proofs of priority of discovery at home and abroad in those experimental facts which have been so highly lauded and spoken of in medical and literary journals, and justly acknowledged in the present era, both in Mexico, Cuba, Spain, France, Russia, and England, by written essays, entitled "Vincit Veritas; or, Truth Conquers," "Pestilence among Men and Animals," and "Practical Original Sanitary Facts," written for the use of the United States Army and Navy, and transmitted by Gen. John A. Dix to the United States Sanitary Commission.

In conclusion, he said that it was the glory of God to conceal a thing, and the glory of man to find it out; and however it suited some minds, at home or abroad, to drink from the "big lake," he, for his part, desired to claim his own original views, and drink out of his own "little rivulet of science;" and, standing on its banks, could reflect on the strange, eventful "destiny" of the past, with hopefulness for the realization of a happier and brighter future.

Dr. Bissell moved that Dr. Brinsmade present to the Publication Committee his remarks concerning the late Dr. Thos. W. Blatchford. Adopted.

Dr. W. C. Anderson moved that a Committee of Hygiene be appointed, composed of five members from this Society, to confer with the authorized officials, and report to this Society. Adopted; and Drs. Bell, Harris, Ordronaux, and McMillan were appointed.

The following papers were read by title, and referred to the Publication Committee:

"Spontaneous Amputation in Utero," by Dr. Armsby.

Also, "Strangulated Congenital Hernia."

"Report of Commissioners of Quarantine," by Dr. Swinburne.

"The Willard Asylum for the Chronic Insane" (bill as passed by the Legislature), by Dr. Cook.

"Cases of Epidemic Cerebro-Spinal Meningitis, or Spotted Fever, with post-mortem appearances," by Dr. J. R. Boulware.

Also, "Cases of Carbonaceous Lung."

Dr. Quackenbush, Treasurer, presented a bill from Chas. Van Benthuysen for printing, which was referred to a committee consisting of Drs. Quackenbush, Huu, and Townsend.

The Society then adjourned *sine die*.

Reviews.

CIRCULAR. No. 6. War Department, Surgeon-General's Office, Washington, November 1, 1865. REPORTS ON THE EXTENT AND NATURE OF THE MATERIALS AVAILABLE FOR THE PREPARATION OF A MEDICAL AND SURGICAL HISTORY OF THE REBELLION. Printed for the Surgeon-General's Office by J. B. Lippincott & Co. Philadelphia, 1865.

THIS circular comprises the report of George A. Otis, Brevet Lieut.-Col. and Surgeon U. S. Vols., who has charge of the surgical records of the Surgeon-General's office; and the report of J. J. Woodward, Assist. Surgeon and Brevet Major U. S. Army, to the Surgeon-General, on the extent and nature of the materials which are available for the completion of the medical and surgical history of the great rebellion. No one will be surprised to hear from Dr. Otis that this material is "simply enormous," and that the "returns are of as huge proportions as the armies that have been engaged in active operations for the past four years." "It is as yet," he says, "impracticable to determine with accuracy the number of wounds received in action during the late war, though data for a near approximative estimate are accessible. But a comparison of a portion of the returns with the complete statistics of other armies, will sufficiently indicate the vast numbers that are dealt with. In the British army in the Crimea, during the entire war, there were 12,094 wounded and 2,755 killed, or a total of 14,849. In the French army in the Crimea, of a total effective force of 309,268, according to the report recently made by M. Chenu, there were 39,868 wounded and 8,250 killed, or a total of 48,118, although in his report of injuries of different regions, M. Chenu records but 26,681 cases. In the late war, the monthly reports from a little more than half the regiments in the field, give for the year ending June 30, 1862, an aggregate of 17,496 gunshot wounds. The reports from rather more than three-fourths of the regiments for the year ending June 30, 1863, give a total of 55,974 gunshot wounds. The battle-field lists of wounded for the years 1864–65, include over 114,000 names. But these returns are to be completed by collating with them the reports of general hospitals, where many wounded were received whose names the recorders of field hospitals or regimental medical officers failed to obtain, and by adding the names of those killed in battle. In comparing the number of cases of some important injury, as, for example, gunshot fracture of the femur, it is found that in the French Crimean army there were 459 such injuries, and in the English army 194, while over 5000 such cases have been reported to this office; or if one of the major operations is selected for comparison, as excision of the head of the humerus, the Crimean returns give 16 of these excisions in the British and 38 in the French army; but the registers of this office contain the detailed histories of 575 such operations."

The surgical specimens of the Army Medical Museum number the enormous figure of 5480. After giving a statement of the successive steps taken to classify properly the surgical records of the office, the consideration of *Special Wounds* and *Injuries* is taken up. The injuries of different parts of the body are treated of, and an outline of the results of treatment

and rates of mortality given, as far as can be done by mere figures and the briefest possible reference to typical and unique cases. We learn that the operation of trephining was performed on 107 cases of injury of the head; 47 of which recovered. In 114 cases in which fragments of bone or ball were removed without the use of the trephine, 61 were fatal and 47 recovered. In 483 which were treated without operation, the ratio was 20·5 per cent. Of 187 cases of gunshot fracture of vertebra, only seven recovered. 73 per cent. of penetrating wounds of chest were fatal, and 26 per cent. of the penetrating wounds of peritoneal cavity recovered. Excision of the hip-joint was the only operation followed by recovery in injuries involving the head of the femur. Of 387 cases of fracture of the upper third of the thigh, 93 were doing well at the end of a year. There were 363 reported cases of tetanus, with 27 recoveries; in two, recovery took place under the use of opiates and stimulants, and in two after amputation. 1037 cases of secondary hæmorrhage have been recorded; of these, 387 were cases of secondary bleeding from a stump, of which 60 per cent. ended fatally, and 650 were cases of secondary hæmorrhage from gunshot wounds, of which 51 per cent. were fatal. The femoral:—In reviewing the recorded cases of secondary hæmorrhage from gunshot wounds, the reporter remarks that, in the earlier part of the war, surgeons were too much in the habit of tying the main trunk at a distance from the wound, but that later, it became the universal practice to endeavor to secure both ends of the bleeding vessel. 754 cases of pyæmia are recorded, and of these 719 were fatal. There are 13,397 amputations recorded for gunshot injury, and in 9705 of these the final results have been ascertained. The rate of mortality is shown regularly to increase as the trunk is approached. Hip-joint amputation has been performed twenty-three times; 9 being primary operations. Of these, 2 of primary and 2 of secondary recovered. The ligature of the larger arteries has been performed 403 times from the beginning of the war to March, 1864. The ratio of mortality for each was as follows:—Common carotid, 75·71; external carotid, 100; subclavian, 80; axillary, 87·50; brachial, 17·18; radial, 14·28; ulnar, 18·18; common iliac, 100; internal iliac, 100; external iliac, 87·50; femoral, 76·85; profunda, 85·71; popliteal, 75; anterior tibial, 31·25; post tibial, 31·57; peroneal, 100; all others, 26·66. The remaining portion of Surgeon Otis's report refers to matters connected with the medical staff of the army and the materia chirurgica. Before concluding a notice of this portion of the work, we would refer to the fact that only seven deaths from chloroform have occurred, and that ether was used in 30 per cent. of all the cases requiring anæsthesia.

Dr. Woodward brings to his portion of the work a remarkable amount of statistical talent and pathological knowledge. The various opinions as well as observations of those who have furnished the original data have been duly weighed. A spirit of justice to all concerned is manifest upon every page. The difficulties that have clustered about his task are stated with fairness, indeed with almost mathematical detail; and we are irresistibly led to adopt the author's own conviction, that with the patient care bestowed upon their compilation, as well as the immense size of the figures considered, the medical statistics of our army cannot well be without practical value.

The space to which we have been compelled to restrict ourselves will not allow us to enter as fully as we should desire upon the consideration of his contribution; we can therefore only pass in review some of the more salient points. Climatic influences in the cause and treatment of disease come in for their share of attention; and for the purpose of comparison, the United States have been divided into three great regions: the Atlantic, the Central, and the Pacific. Thus the Government, as far as the exigencies of the service permitted, at a comparatively early period in the war, adopted, upon the recommendation of its Medical Department, the policy of transferring the sick and wounded to hospitals in more northern latitudes, with the most gratifying results.

The section devoted to mortality rates is a well digested array of facts and figures. We are informed that our losses from disease, during the first half of our struggle, were proportionately less than those of the allied armies in the Crimea, or of our own army in the Mexican war. The mortality was greatest in the Central, and least in the Pacific region. In the former, the extent of territory, with operations remote from the base of supplies, along with exposure to miasmatic influences, and in the latter conditions of life almost identical with those in times of peace, are allowed their share of modifying influence.

In the general prevalence of disease, the Central region still maintains the preëminence in the ratio per 1000 of mean strength. In the constant sickness rate, the Atlantic region slightly exceeds the Central; the rate in both, however, is about 10 per cent. of the strength, while, in the words of the author, "the rate for the Pacific region, 7 per cent., is in striking contrast with the slight mortality of that region."

Omitting the section devoted to the consideration of the comparative frequency of the several diseases, we come upon some interesting facts relative to camp-fever, or, according to Dr. Woodward's nomenclature, adopted by the Medical Bureau, typho-malarial fever. The Pacific region appears to have been comparatively exempt from this scourge, while the Central suffered the most in mortality and frequency of invasion. A diagram constructed to show what our author calls "the season wave," expresses the autumnal character of all those fevers, which, for practical purposes, have been grouped together under this new designation.

We agree with our compiler that many of the reported cases of typhus were instances of mistaken diagnosis, and endorse the wisdom of their comprehension under the head of "typho-malarial fever." Still, the occasional occurrence of this disease is not denied in connexion with "crowd-poisoning" influences.

A brief allusion to the possession of some materials relating to spotted fever, made up of autopsical reports, etc., and a notice of the yellow-fever outbreak at Key West, Florida, in July, 1862, and the epidemic at Newbern, N. C., in 1864, conclude this portion of the circular. The publication *in extenso* of several papers upon the latter subject, in possession of the Department, are promised in the Medical History of the War, which we are elsewhere informed will attain the dignity of three quarto volumes.

262,807 cases of intermittent fever are reported as having occurred in two years. These include all types—even the congestive, or pernicious fever of Dr. Wood—which last form helps to swell the mortality rate from one death in every 631 cases to one in every 147. The frequency of attack and mortality was greater in the second than in the first year, and in the Central than in the Atlantic region.

A few remarks upon jaundice bring us to what many an army-surgeon has viewed as the opprobrium of his science—diarrhœa and dysentery. They are discussed in conjunction, and no one condition is credited with their causation. A scorbutic taint, malarial influences, crowd-poisoning, the heat of summer, fatigue, and the

use of water with saline or organic impurities, constitute the chief, but not the only explanation of their origin. After camp fever, this class of diseases has most fearfully decimated our forces; and here again the Central region, viewed in its territorial integrity, has the largest number of representatives upon the mortality lists. The lesion is determined as a chronic ulcerative colitis, occasionally an entero-colitis; and to the former condition there is occasionally superadded a yellowish false membrane of more or less depth of tint, "composed of innumerable round cells, held together by an adhesive granular matrix, more or less resembling coagulated fibrin." Tubular casts of this pseudo-plastic substance have been found in the stools of patients who subsequently recovered. Diphtheria, pneumonia, congestion of the lungs, serous apoplexy, and Bright's disease of the kidneys, are among the leading complications. In the stools the microscope has developed mucus, blood, undigested particles of food, and torula cells. Experience seems to have settled the point that all recommended therapeutical agents are but subservient to proper dietetic and climatic influences.

We have now come to consider the diseases of the respiratory organs. The statistics show the greatest mortality from pneumonia, aggravated of course by the usual season influences. Our figures, though large, and perhaps in every instance not absolutely correct, still fail to attain the standard in fatality reached by the British in the Crimea.

The amount of scurvy reported was comparatively small, and the mortality unprecedented. The generous alimentation proved an excellent prophylactic; still the scorbutic taint was not altogether absent, and may have been reported under the head of rheumatism, neuralgia, lumbago, and even malingering.

The statistics of "discharges on surgeon's certificate of disability" are not yet complete, and subsequently modified as they were by more stringent orders or fuller instructions in the premises, we for the present refrain from quoting.

Closing with a compunctious throb the doors of the Army Medical Museum, with its rich pathological stores illustrated by many collateral aids; even denying ourselves the time to admire the beautiful chromo-lithographic representation of the "ileum in malarial form of typho-malarial fever," and the engraved copy of a micro-photograph, given as an earnest of what may be expected in the further development of the art, we pass on to the exceedingly interesting chapter on hospital organization and construction.

"Never before," remarks Dr. W., "were such establishments, in time of war, so little crowded or so liberally supplied." * * * * "Never before, in the history of the world, has the mortality in military hospitals been so small; and never have such establishments so completely escaped from diseases generated within its walls." To all of which we yield our cordial though unneeded assent. To say that the typography of the work is superb and the plates magnificent, would be giving but a faint idea of its real excellence in this respect.

RHINOSCOPY AND LARYNGOSCOPY; THEIR VALUE IN PRACTICAL MEDICINE, by DR. FRIEDRICH SEMELEDER, Physician in Ordinary to his Majesty the Emperor of Mexico; Member of the Royal Medical Society of Vienna, and of the Medical Society of the Pantheon in Paris; formerly member of the Medical Faculty of the University of Vienna, and Surgeon to the Branch Hospital at Gumpendorf. Translated from the German, by EDWARD T. CASWELL, M.D. With woodcuts and two chromo-lithographic plates; pp. 191. New York: William Wood & Co., 61 Walker Street, 1866.

THE work before us is the production of the gentleman to whom, probably, if we except Professor Czermak, the profession owes the most as the utilizer of the arts of rhinoscopy and laryngoscopy. The description of the practice of rhinoscopy occupies, comparatively, a large space in Dr. Semeleder's volumes. This is as it should be, for in this country the sum of our knowledge on this subject may be said to be nothing. The anatomy of the naso-pharyngeal space is fully given, and is accompanied by an illustrative plate, a sectional view, which will repay study and verification. The faucial orifice of the Eustachian tube, the sinus or fossa of Rosenmüller, even in the midst of the ample material of our dissecting-rooms, are not so familiar to medical men as parts much less accessible.

Dr. Semeleder's apparatus for examination consists of the right-angled jointed tongue-spatula, a mirror of steel or glass coated with quicksilver from 1 to 2 centimètres in diameter. Mirrors are preferred on which the angle of attachment to the rod approaches nearly to a right angle. Palate-hooks are also used; but no very clear account of them is given. More light is said to be needed for the examination of the posterior nares than for the larynx. The author throws a cone of light into the room by means of a concave mirror attached to the window upon which the sun shines; he then seats himself and the patient within this cone, and collects anew the diverging rays by means of the illuminating apparatus. Dr. Semeleder is not yet an advocate of the more elaborate methods of illumination; when artificial light is to be used, the light of any good lamp suffices.

Semeleder's illuminating-spectacles, consisting essentially of a spectacle frame, to the bridge of which a concave mirror is attached, have proved to be a practical and popular means of illumination.

"The practice and adroitness of the observer," are said to be "more important than on the examination of the larynx." Various methods are suggested for the anterior examination of the nares,—pressure at the tip of the nose, the use of valvular ear specula, and Voltolini's method of sliding an ear catheter or a bright straight tube (such as the endoscope) into the nasal cavity.

Cases in aural surgery as well as of polypi, ulcers in the region of the posterior nares, some of them very striking, and which owe their interest to the revelations of the rhinoscope, with a few remarks on the instrument for the local application of remedies to the naso-pharyngeal space, close this very satisfactory portion of the volume. The part devoted to laryngoscopy contains a description of the methods of practising the art, the physiology of the larynx, and the diseases of its various tissues. The translator's appendix, which is familiar to many of our readers, having been presented to them in the *American Medical Times*, consists of the description of the extirpation of polypi in the larynx by Dr. Semeleder—a very difficult operation, although the distinguished gentleman's boasting over "German cold-bloodedness" sounds a little queerly to American professional ears.

The translation, as we should expect from the accomplished scholar who did it, is well done. If we had any suggestions as to the rendering into English to make, perhaps we might say that it is hardly fair to translate the verb *orientiren*, by *orient*, page 51; "one needed ample time to orient himself." Our verb orient, however well understood by civil engineers, is hardly classical English. Then, again, why does Dr. Caswell say

"*Polyp*" for *Polypus?* An index would enhance the value of the book, although the table of contents is full. We believe that Dr. Caswell, in thus giving to the American profession this work of his friend and distinguished instructor, has done us an important service. He has put into our hands a volume much better than any compilation on the same subject, containing as it does the unadulterated views and experience of one of the earliest and most successful cultivators of rhinoscopy and laryngoscopy.

Improvements in Instruments.

BUTTLES' INHALER, AND ITS MODIFICATIONS.

THE application of vapors directly to the mucous membrane of the nasal and air-passages is becoming quite a fashionable mode of treatment. The great favor with which the inhalation of the vapor of iodine is now being received, is perhaps an explanation of this.

Various forms of instruments have been invented for the purpose of utilizing this system of medication.

The first apparatus of the kind was devised by Dr. M. S. Buttles, of this city, some months ago, and is represented by Fig. 1. It consists of a hollow, pyri-

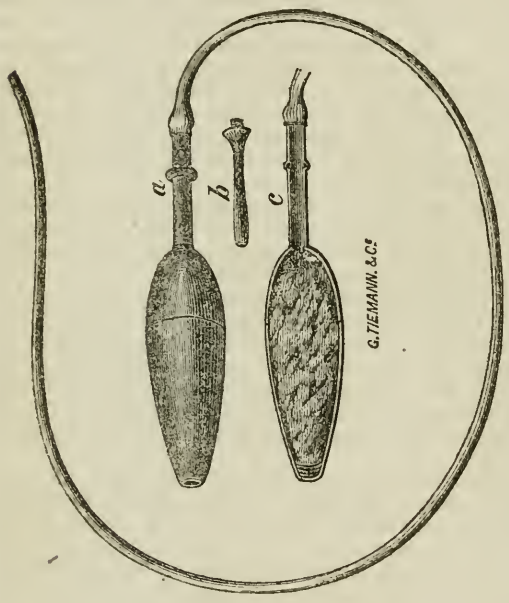

FIG. 1.

form-shaped bulb of hard rubber, to one extremity of which a nozzle (*b*) can be screwed; while to the other a tube (*a*) is also attached, which forms the medium for the application of the rubber-tube. The bulb is divided into two parts, for the purpose of introducing and removing a sponge, which contains the various remedies, the vapors of which it may be desirable to inhale. For ordinary use, the tapering end of the bulb is either inserted into the nostril, or the end or even the whole of the bulb may be introduced into the mouth. The same principle applies in either case, viz.—the application of vapor by means of inhalation, directly to the mucous surfaces of the nostrils and fauces. The pipe (*b*) is only designed to be used in cases occurring in children, when it may be necessary to blow through the elastic tube.

An increased range of application for Buttles' instrument has been made by Dr. D. B. St. John Roosa, who combines with it an India-rubber air-syringe, as in the manner represented in Fig. 2. The air-bag is the same as is used in Politzer's method of rendering pervious the Eustachian tube. Instead of the tube (*b*) in Buttles' apparatus, Dr. Roosa has adapted a flattened spoon-shaped rubber-bulb with perforations, which is very convenient for introduction into the nostril. The combination of Politzer's air-bag with the original inhaler, was made for the purpose of treating more particularly diseases of the middle ear, and for injecting medicated vapors into the cavity of the tympanum; but we see no reason why it could not have a more extended application, and be used in the treatment of all those catarrhal affections in which it might be necessary to bring medicated vapors in more perfect contact with those parts which might be beyond the reach of cur-

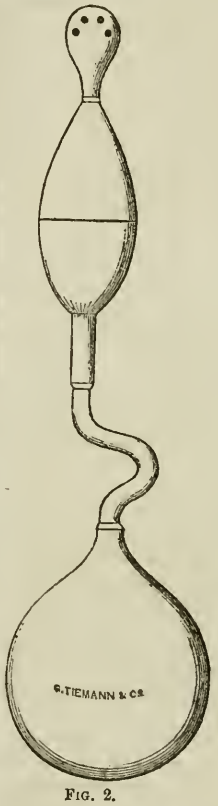

FIG. 2.

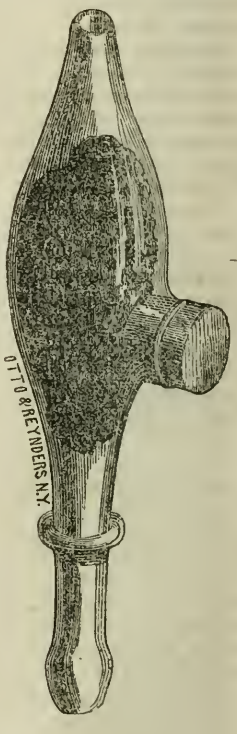

FIG. 3.

rents induced by ordinary inspiration. Why could it not be used by the application of a proper nozzle for throwing vapors into the vagina, cavity of the uterus, into the rectum, and even into the urethra and bladder?

Dr. O. D. Pomeroy, also of this city, after using quite extensively Dr. Buttles' inhaler, found that it was acted upon when certain materials were used, and more especially was this the case in reference to chloroform. This led him to have the bulb constructed of glass. It has, as will be seen by a reference to the wood-cut, Fig. 3, a somewhat different shape from Dr. Buttles'; and instead of being divided into two portions, has a neck through which the sponge may be introduced or withdrawn by means of a forceps. A cork closes the opening of this neck. The nozzle of the instrument is bulbous at its extremity, for the adaptation of elastic tubing, when it is found necessary to

connect it with any other instrument, such for instance as a catheter. The other extremity of the instrument is tapering for introduction into the nostrils. The advantages of Dr. Pomeroy's modification over the original instrument are: the ease with which it may be cleansed; the impossibility of its being acted upon by corrosive substances and solvents: and last, but not least, its cheapness. The glass is made thick enough to prevent its being easily broken. The first instrument has the advantage over this one, in allowing of its complete introduction into the cavity of the mouth—an impossibility with Dr. Pomeroy's apparatus, on account of the position of the neck at right angles with the body.

Correspondence.

DOMESTIC.

Chicago, Feb. 1866.

To the Editor of the Medical Record.

Sir:—The atmosphere of our medical circle in this city was agreeably stirred the other day by the appearance of the first number of "The Medical Record." For several weeks past we have been welcoming the journals to which the return of peace has given life throughout the country; and now, to cap the climax, *primus inter pares*, this new semi-monthly appears. Combining the elaborate strength of a monthly publication with the lighter graces of a weekly, it cannot fail to meet with universal favor.

An interesting subject is this of medical journalism. The ambition of the schools finds its expression in the local weeklies or monthlies which originate from so many separate centres throughout the country. These serve to keep alive the affection of the alumni for their Alma Mater, to afford the means of communication between the professors and their former pupils, and to gather up the experience of the hundreds of physicians whose horizon is necessarily limited by the circle of their practice, and by the reminiscences of their undergraduate studies at the medical college. Most useful and worthy of approbation are the periodicals of this class. Then come the solid metropolitan monthlies, which address themselves to a wider range of readers, reflecting the practice and the precepts of the chiefs of medicine, and picturing forth the hospitals, lecture-rooms, and society-halls of the most favored centres of learning. To this class also must be referred the more ponderous quarterlies, which furnish light reading for medical philosophers, and utter oracular sentences for the busy practitioner who has neither leisure nor the purse for separate monographic volumes. Invaluable to such men is a work like *Braithwaite's Retrospect*, which affords a glimpse of the great world of medical learning across the ocean. All these publications have their sphere, serve their purpose, and find their level. So, after wading through the "weightier matter of the law," and brushing aside the lighter themes of the local press, it is with unfeigned satisfaction that we hail the appearance of a Medical Record, which by its frequent issue shall sustain, without flagging, the interest of the reader, while its well digested matter shall provoke the attention of the student, and rescue his mind from the danger of frivolous reading.

Our city affords little that is new in matters pertaining to medicine. The close of the war has favored us with the presence of a host of returned army surgeons, who seek to replace the excitement of battle by the stern joys of a conflict with fortune in the ranks of a crowded profession. Some will drift into other callings; some will grow weary and faint by the way; success will meet only those who watch and wait—*and work*.

The annual commencement of the Rush Medical College occurred on the 24th of January. Ninety young men were admitted to the degree of M.D. The learned Professor of Physiology, Dr. Freer, presided in the absence of the President of the Faculty, Prof. Brainerd, who has recently left Chicago for an excursion to Europe. During his absence the chair of Surgery is filled by Dr. Powell, an accomplished young surgeon, who for several years has held the position of Demonstrator of Anatomy to the College. Dr. Lackey, one of the editors of the Chicago *Medical Journal*, succeeds to the place thus made vacant by the promotion of Dr. P.

The Chicago Medical College is still in session, as its winter term is five weeks longer than the term at the old school. The ex-President of the American Medical Association manifests all his youthful assiduity, and still finds time to lecture daily at the college or in the wards of the Mercy Hospital, to act as sole editor of the *Medical Examiner*, and to meet all the requirements of perhaps the busiest practice in the city.

A new impetus has been recently given to the study of medicine in this city by the opening of the Cook County Hospital. The building is situated in the southern quarter of the town, and during the war was used by the U. S. authorities as a hospital for the treatment of diseases of the eye. The end of the war vacated its wards, and restored it to the direction of the Supervisors of the county, who proceeded to refit the building, and to open it for the reception of the pauper sick, whose necessities for the last four years have been quite overlooked. The treatment of the patients is placed in the hands of a medical board of physicians and surgeons, and there is a resident house-staff, consisting, at present, of a house-physician and surgeon, with an assistant, who are appointed after examination by a committee of the Medical Board, precisely in accordance with the practice which obtains in New York at Bellevue and the Island hospitals. Our hospital has a capacity of two hundred and fifty beds, and is, in the plan of its construction and in all its appointments, quite equal to similar charitable institutions in the older cities of the country. Clinical instruction has been already inaugurated by the visiting physicians and surgeons, who have thrown open the wards for a public clinic every Tuesday and Friday at half-past one o'clock P.M. These opportunities seem to be highly appreciated, not only by the students from the college, but by many of the physicians resident in town. As the surgical theatre and the pathological room already afford chances for observation superior to anything ever before enjoyed in this city, it is reasonable to anticipate that the time is not distant when the clinical advantages of our hospital will supplement the attractions of our colleges in a ratio fairly comparable to that which exists between the schools and the hospitals of New York and Philadelphia.

The Chicago *Medical Journal* has just commenced its twenty-third year under a new editorial corps, consisting of Dr. E. L. Holmes, H. M. Lyman, and R. M. Lackey.

Dr. Holmes is already well known as one of the most distinguished oculists in the United States. The names of his associates are new to the profession, but the improved appearance of the Journal leads us to hope that it may prosper under their care. The Journal is one of the oldest medical publications in the West, and the pages of its file illustrate well the progress of the country. The names of the gentlemen who have in past years been connected with its editorial management are household words throughout the

North-western States, and their recital carries one directly back to those days—so comparatively recent in time, yet so distant in contrast with the present—when Chicago was but a straggling village on the swampy shore of Lake Michigan.

PHILADELPHIA, Feb. 1866.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Never, since the winter before the commencement of the war, has our lecture season been so successful. The classes at both our schools are large, and the prospect of proportionally large graduating classes is excellent. In a casual dropping in at lectures, I have been surprised and delighted at the attention and respect shown the lecturers. In this respect a most marked improvement has occurred. Long may it continue. I am unable to chronicle anything specially new at either school in regard to themes, etc., and believe the season will close as quietly as it has progressed.

While we have ample room, material, and opportunity for another school, yet there appears at present no indication by which to anticipate any movement in that direction. Nor has there been any effort to increase the usefulness of the existing institutions by the addition of those adjunct professors, who, by proper employment, may add vastly to the field from which to glean a proper knowledge of our noble art.

There was indeed some talk of a summer-school, but that appears to have been abandoned; and your city, by the energy and industry of her teachers, bids fair to draw off not only our surplus, but even to trench fearfully upon the main body of our usual classes.

In regard to societies we are better supplied, and the meetings are generally fully attended, and able discussions are had almost weekly.

The subject of puerperal fever has occupied two meetings of the Philadelphia County Society, and elicited warm discussions on both occasions. The nature of this malady, and the question as to its contagiousness, were the main points; and both sides ably sustained their parts.

Cholera was a subject which attracted enormous meetings, and full discussions ensued, resulting in the appointment of a committee, whose able report was published in the secular journals, and which, I am fully satisfied, awoke the people to the necessity for cleanliness, care in diet, and at the same time allayed the groundless apprehensions of many, who feared they knew not what.

Prof. Leidy gave a very able and interesting lecture on Human Entozoa, which, I regret to say, was not reported for publication. He rendered his lecture still more valuable by numerous drawings, specimens, etc.

From these, and many other evidences, it would appear that the County Society is by far the most popular and energetic of the medical organizations.

The College of Physicians, dignified and slow, holds monthly meetings, at which are presented cases, specimens, books, etc.; but no regular debates are held, and hence its meetings are attended, as a general rule, by a select few. The subject of cholera in all its bearings is in the hands of a committee, who are expected to report some special action; and if our usually unimpressible Board of Health and Councils can be affected, it is thought this body has weight enough to do it. We shall see!

The Pathological Society, smallest in numbers, meets about once a month. Specimens are presented with all their details, and a very full summary appears quarterly in the American Journal.

Perhaps the most lively, best attended for its size, and most sociable of our organizations, is the Northern Medical Association. This body organized about 1847, long before the County Society; has held semi-monthly meetings ever since. The attendance is full, and the members, being all well acquainted with each other, enjoy the fullest freedom in debate, and certainly manage to obtain the fullest knowledge of every subject they discuss.

Our clubs, for which Philadelphia has ever been famous, appear to be decreasing rapidly, both in number and usefulness. Virtually, the only one at present in operation is the "Tuesday Evening Club," which, I opine, is not as well attended as formerly. Perhaps nothing has kept us more like brothers than these little re-unions, where gossip, medicine, and good eating occupy the evening, and from which the stranger retires with a feeling that it "was good to be there."

The Pennsylvania Hospital in the heart of the city, and the Philadelphia Hospital across the Schuylkill, have both attracted full classes twice a week. The latter abounds in material, and would make a most valuable groundwork upon which to build a medical school similar to your Bellevue.

The health of our city is certainly good; scarcely any disease appears to exist, and our bills of mortality exhibit a gratifying index for those who delight to study them. The action already taken on the subject of cholera has driven from our doors many pest-places, which would have acted in the spring as salient points for disease and death.

Yours,

N. E. M.

New Publications.

ANNOUNCEMENTS OF NEW BOOKS.

WILLIAM WOOD & Co. New York:
Beale on the Tissues.
Seguin on Idiocy.

LINDSAY & BLAKISTON, Philadelphia:
Waring's Therapeutics.
Trousseau's Clinical Medicine.
Tanner's Index of Diseases and Treatment.
Remarks on Neurosis.

JOHN CHURCHILL & SONS, London, England:
Beale on Nerves and on Inflammation.
Savage on Female Pelvic Organs. 4to. 2d edition.
Wells on Ovaries. Vol. 2.

BOOKS AND PAMPHLETS RECEIVED.

PRACTICE OF MEDICINE, by AUSTIN FLINT, M.D., Professor of Principles and Practice of Medicine, Bellevue Medical College, &c. Philadelphia: H. C. Lea. 8vo. pp. 858.

THE PHYSIOLOGY OF MAN. Introduction—The Blood; Circulation; Respiration, by AUSTIN FLINT, Junior, M.D., Professor of Physiology and Microscopy, Bellevue Medical College. New York: D. Appleton & Co., 1866. 8vo. pp. 495.

A PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, &c., by WILLIAM ROBERTS, M.D., Fellow of Royal College of Physicians of London, &c. Philadelphia: H. C. Lea, 1866. 8vo. pp. 512.

THE EASTERN TURKISH BATH, by ERASMUS WILSON, F.R.S., with Notes and Appendix by M. L. HOLBROOK, M.D., 12mo. pp. 72; also ALCOHOLIC MEDICATION, by R. T. TRALL, M.D., 12mo. pp. 48. New York: Miller, Wood & Co., 1866.

THE ANNUAL DISCOURSE BEFORE THE MASSACHUSETTS MEDICAL SOCIETY, May 31, 1865, by BENJAMIN E. COTTING, M.D.

Statistics of Insanity, by Richard J. Dunglison, M.D., Physician to Bond Orphan Asylum.

Introductory Lecture; delivered at the reopening of New Orleans School of Medicine, by Professor E. D. Fenner.

Catalogue of Officers and Students of the University of Michigan, 1866.

On Epidemic Cholera, &c., by Nelson L. North, M.D., Surgeon of Metropolitan Police, Williamsburgh, N. Y. 8vo. pp. 39.

Report of Buffalo General Hospital for 1865.

Glycogenic Function of the Liver; also Sunbeam and Spectroscope, by Professor Howard Townsend, Albany, N. Y.

Twelfth Annual Report of the N. Y. Infirmary for Women and Children, 1865.

Rhode Island Twelfth Registration Report for 1864.

Annual Report of Surgeon-General, U.S.A., for 1865.

Medical News.

Appointments.

Bellevue Hospital.—Dr. J. W. Southack, Jr., has been appointed Curator to this institution.

Personal.

Dr. B. Fordyce Barker recently recovered five hundred dollars, with interest, from a patient's father. No defence set up, although it was stated during the trial that a special agreement had been entered into to cure. This statement the plaintiff contradicted in his evidence.

A Memorial of John W. Francis, M.D., LL.D., from the pen of H. T. Tuckerman, Esq., giving more particularly the social phases of his life, has recently appeared.

Prof. Jeffries Wyman has accepted the Professorship of Comparative Anatomy in the medical department of Harvard University.

Prof. C. A. Lee, formerly of Peekskill, N. Y., is about locating in this city.

Dr. John G. Adams will shortly sail again for Europe, to be absent for two years.

Dr. Benj. Ogden, who has been for several months afflicted with hemiplegia, is improving.

Dr. Thaddeus M. Halsted, late Surgeon to the New York Hospital, after being absent from the city for some time past, has returned and resumed practice.

Dr. J. McKnulty, who was so seriously injured by a fall from his horse while in service, is rapidly improving from his paralysis.

Prof. J. C. Draper, of the New York Free Academy, has just published a work on Physiology, which is designed more especially for the use of schools and academies.

Prof Frank H. Hamilton is at work on a new edition of his Fractures and Dislocations.

Dr. Alexander Murray, formerly Physician to the "Heart and Lung" class, and more recently Trustee of the Eastern Dispensary, has resumed his relations to the institution as physician to the class of "Diseases of Women."

The Metropolitan Board of Health.—The following are its members: Police Commissioners Thomas Acton, James G. Bergen, Joseph S. Bosworth, and Benj. F. Manierre, Treasurer; and Drs. J. O. Stone, W. Parker, and James Crane of Brooklyn; and Dr. John Swinburne, Health Officer. Jackson A. Shultz, Esq., who is also a member, is the President of the Board. Col. E. Clark has been appointed Secretary of the Board; Dr. E. B. Dalton, Sanitary Superintendent; Dr. E. Harris, Registrar of Records; and Col. George Bliss, Jr., Attorney. The officers' salaries have been fixed as follows: General Superintendent, $4000; Assistant Superintendent for Brooklyn $2,500; Secretary, $2,000; Registrar, $2,500; Sanitary Inspectors, $1,200.

N. Y. County Medical Society.—A stated meeting of this Society was held on the evening of March 5th, at the College of Physicians and Surgeons, Dr. T. C. Finnell in the chair. Dr. William B. Bibbins read a biographical sketch of the late Dr. D. S. Conant, after which Dr. Joel Foster made some remarks upon the cholera of 1832. He detailed some of his experience in the treatment of the disease by very large doses of calomel, in conjunction with warmth to surface, hot injections, etc. Dr. W. H. Thomson then followed with a very interesting paper upon Chlorosis. He is to continue the paper at the next meeting. The following delegates to the next meeting of the American Medical Association were elected:—Drs. Farrington, Ramsay, J. C. Smith, Downs, Hubbard, Finnell, Connolly, Lynch, Jno. Shrady, Leaming, Peaslee, Rogers, Sayre, Thoms, Bulkley, Warner, Farnum, Prince, Bahen, and Lawrence.

The East River Medical Association held a regular monthly meeting, March 6th. Dr. S. Waterman read a lengthy paper upon Scarlatina. Delegates to the American Medical Association will be elected at the next meeting.

New York Academy of Medicine.—At the meeting held March 7th, 1866, the discussion on cholera was resumed. Dr. L. A. Sayre, who opened the discussion, stated it as his belief that cholera was always carried from place to place, and that in order to guard against an invasion of the disease a rigid national quarantine should be enforced. He was followed by Drs. E. Harris, W. H. Draper, Vandeveer, and Herzog. The following gentlemen were elected Resident Fellows—Drs. Jarvis N. Husted, John A. Lidell, Jerome C. Smith, J. W. Purdy, and Howard Pinkney.

The Obstetrical Section of the New York Academy of Medicine held its last regular monthly meeting, February 19, at the house of the chairman, Dr. Joseph Worster. The discussion upon "Dysmenorrhœa" was the order of the evening, and was partaken in by Drs. Peaslee, Emmet, Prince, and others. This, we understand, is the only section of the Academy which is actually in existence—at least the only one which holds regular meetings.

Officers of N. Y. Obstetrical Society.—The following gentlemen have been elected to serve for the ensuing year: Dr. T. G. Thomas, President; Dr. Chas. Henschell, Vice-President; Dr. John G. Perry, Recording Secretary; Dr. Abraham Jacobi, Corresponding Secretary; and Dr. F. N. Otis, Treasurer.

Officers of the New York Pathological Society.—At the annual election of the New York Pathological Society, held Jan. 10, 1866, the following officers were elected to serve the ensuing year: Dr. Frank H. Hamilton, President; Drs. W. H. Draper and H. D. Noyes, Vice-Presidents; Dr. Geo. F. Shrady, Secretary; and Dr. W. B. Bibbins, Treasurer.

Bellevue Hospital Medical College.—The fifth annual commencement of Bellevue Hospital Medical College was held on the evening of the 24th ultimo, at the Academy of Music. There were 172 graduates. Addresses were delivered by Dr. Taylor, President of

the Faculty; Wm. M. Evarts, Esq.; the Hon. Simeon Draper, President of Board of Trustees. The Valedictory was pronounced by Leroy M. Gale, of the graduating class.

Medical Department of the University of N. Y.—The annual commencement of the Medical Department of the University of the City of New York took place on the evening of March 2d, 1866. Seventy-eight gentlemen received their degree of M. D. *in course*, and Shirly Abela, of Illyria, and Samuel B. Crawford, of Pennsylvania, *causa honoris*. The Mott bronze medal was awarded to Mr. Frank L. Satterlee, of N. Y.; the Van Buren prize to Mr. Juan Flores, of Costa Rica; and the Metcalfe prizes to Dr. Henry B. Forbes of Canada West, and Dr. James G. Burnet of New Jersey. The Chancellor announced the continuance of the Mott medals in perpetuity. The Valedictory Address, in verse, was delivered by Prof. Alfred C. Post.

College of Physicians and Surgeons.—The fifty-ninth annual commencement of this institution took place on the evening of March 9, 1866, in the Rev. Dr. Crosby's Church. An address to the graduating class was delivered by the Rev. Sullivan H. Weston, D.D., and the Valedictory by Dr. H. D. Nicol, of the graduating class. The number of graduates was 112. The following prizes were distributed:—1st Harsen prize, to Neil J. Hepburn; 2d Harsen prize, to Luiz Henrique Farreira D'Aguicar, Jun.; the 3d Harsen prize to John Petrie, Jun.; the 1st Thesis prize to J. Williston Wright; and the 2d Thesis prize to Gerardus H. Wynkoop.

The New York Society for the Relief of Widows and Orphans of Medical Men, according to the annual statement for 1865, has 109 members. Its invested funds now amount to $56,500. Income during the year, $10,013.37. Dispursements to annuitants, $1125.

The New York Infirmary for Women and Children, which has been in existence for twelve years, is still in successful operation, and is yearly increasing in usefulness. The attending physicians are, Drs. Elizabeth Blackwell and Emily Blackwell—Dr. Lucy M. Abbot being the assistant physician. The institution consists of a dispensary and well regulated hospital. During the past year, five thousand eight hundred and ninety-two persons have sought relief in the different departments; fifty-four hundred and fifty-two being treated in the dispensary, one hundred and six received into the house, and three hundred and thirty-four visited at their homes. It is the purpose of the managers of the institution to establish in connexion with it a school for the education of female physicians; and of the hundred thousand dollars which are said to be required for the proper carrying out of this plan, twenty-one thousand are already subscribed by some of our substantial and moneyed citizens, all of which will be paid in as soon as thirty thousand are pledged. The promise, considering the present indications, is a very good one, of our soon having in our midst a well conducted Female Hospital Medical College, which shall meet all the requirements in the case.

Relief for Indigent Cripples.—The New York Society for the Relief of the Ruptured and Crippled, held their quarterly meeting at Room 39, Bible House, on the 13th instant, when Dr. Knight, resident physician and surgeon, presented the following report for the quarter ending February 1st: Three hundred and twenty patients, for whom new surgical apparatus were required, received treatment, and one hundred and forty-six out-door patients were continued under treatment.

Of in-door patients, there are twenty-six little cripples children; six were discharged relieved during the quarter, and others received in their place, while many are waiting to be admitted. Only twenty-six can be accommodated in the rooms of the Society, at 97 Second avenue. A discussion ensued as to the possibility of enlarging these premises, and of obtaining means for that purpose previous to the time when the society will be enabled to erect a hospital adequate to the wants of the city for the relief of cripples. The officers of the society are:

President—John C. Green; *Vice-Presidents*—James Lenox, John David Wolfe, Stewart Brown, and A. R. Wetmore; *Treasurer*—Jonathan Sturges; *Corresponding Secretary*—R. M. Hartley; *Recording Secretary*—Joseph B. Collins.

New York Opthalmic School and Hospital.—The number of patients treated during the past year was 1030; which, according to the surgeons' report, is a decided increase over previous years. Its fourteenth annual commencement was held on Friday evening, the 23d ult. Twelve graduates received their diplomas upon the occasion.

Nursery and Child's Hospital.—The net proceeds of the Charity Ball, given January 29, 1866, for the benefit of the Nursery and Child's Hospital, were, according to the recent report of the treasurer, $11,941.

Examination by Naval Medical Board.—Boards of Medical Officers will convene at the Naval Hospital, Chelsea, Mass., Naval Hospital, Brooklyn, N. Y., and Naval Asylum, Philadelphia, Pa., on Monday, March 12, 1866, for the examination of candidates for admission into Medical Corps of the Navy.

Qualifications.—Letter stating residence, place and date of birth, together with the expressed wish by which board examination is desired, and accompanying testimonials of moral character, to be addressed to the Honorable Secretary of the Navy, or to P. J. Horwitz, Chief of the Bureau of Medicine and Surgery, Navy Department, Washington, D. C. Age not under 21, nor over 26 years. Expenses during examination not allowed by government to candidates.

Home for Destitute and Disabled Soldiers.—The Ira Harris United States Hospital at Albany, N. Y., has been converted into a home for destitute and disabled soldiers of the State. One hundred have been received. The institution has accommodations for three hundred. They are provided for at the expense of the State.

Statistics of Army Medical Staff.—Since April 1861, there have been appointed (547) five hundred and forty-seven Surgeons and Assistant Surgeons of Volunteers;

Mustered into service (2109) two thousand one hundred and nine Volunteer Regimental Surgeons, and (3882) three thousand eight hundred and eighty-two Volunteer Regimental Assistant Surgeons; employed as Acting Staff Surgeons (75) seventy-five, as Acting Assistant Surgeons (5532) five thousand five hundred and thirty-two. As far as returns have been received, during the war (34) thirty-four officers of the Medical Staff have been killed, or died of wounds received in action (24), twenty-four wounded, and (183) one hundred and eighty-eight have died from disease or accident incurred in the service; (1) one died in a rebel prison, (6) six of yellow fever. A completed record will increase this number. Two hundred and fourteen (214) Surgeons and Assistant Surgeons of Volunteers, reported as supernumerary, have been mustered out.—*Annual Report of Surgeon-General, U.S.A., for* 1865.

Errata.—Page 19, Prof. Hamilton's Clinics, 3d paragraph, 15th line, read *gaps* instead of *flaps*. Page 20, 3d paragraph, line 2, read *or* instead of *on*.

ON CHRONIC URETHRAL DISCHARGES;

BEING THE SUBSTANCE OF A CLINICAL LECTURE DELIVERED AT THE UNIVERSITY MEDICAL COLLEGE DURING THE WINTER OF 1865-66.

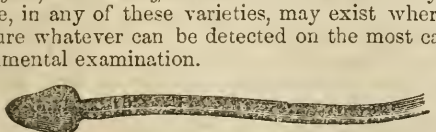
By W. H. VAN BUREN, M.D.,

PROFESSOR OF ANATOMY, &c., &c.

In a very large majority of the cases applying for relief with chronic discharge from the urethra, commonly known as gleet, we find that this discharge is merely a symptom of a more serious disease, viz. stricture of the urethra. Hence the clinical rule so commonly enforced by good surgical authorities: *in all cases of long standing urethral discharge, examine the patient for stricture.* The reasons for this rule are obvious. The more essential consequences of contraction of the calibre of the urethra, viz. a diminished volume of the stream of urine, and the necessity of a longer time and more effort to empty the bladder, are not present in the earlier stages of the disease, which is notoriously insidious in its progress; and they always advance so slowly as not to attract the attention of the patient until the stricture has already existed for some months—often for years. Hence he frequently has no knowledge of its existence until it is ascertained by a surgical examination; complaining only of the more obvious symptom, the gleety discharge.

The nature and amount of this discharge vary so greatly in different cases that no evidence of the presence or absence of stricture can be gathered from *its* examination. It may be profuse and purulent in character, as when furnished by a false passage which complicates the stricture. It may be transparent and scanty, or variable in quantity and color from irregularities in diet and drink; or apparently absent entirely as a discharge, and only visible in the shape of yellowish-white filaments floating in the urine after it is voided, washed out and rolled into shreds by the stream as it passes through the canal. I have often examined these minute floating particles under the microscope; they consist of pus corpuscles enveloped in mucus, rolled into thread-like masses by the friction of the urine against the urethra. Besides these microscopical elements we find also in the discharge of gleet the debris of the different varieties of epithelium from the urethra, the ducts of Cowper's glands, the ducts of the prostate and ejaculatory canals, and occasionally casts from the cæcal pouches or follicles of the prostate itself.

The discharge is furnished not only from the altered surfaces of the urethra which correspond with the stricture, but often from the *inflamed membrane lining the dilatation of the canal which always exists, in a greater or less degree, immediately behind the stricture.* Finally, discharge, in any of these varieties, may exist where no stricture whatever can be detected on the most careful instrumental examination.



And now let us consider the best mode of examining the urethra, in a case of gleet, to detect the existence of a stricture, if present; for this purpose you require a flexible bougie with a bulbous expansion at its extremity, of the above model:

It is of French manufacture, and known as the *bougie à boule.* It is made of different sizes, ranging from No. 1 to No. 14 of our scale. Notice that its somewhat olive-shaped extremity is conical, tapering to a rounded point, with a more abrupt bevel at its shoulder. You select the largest of these bougies which the orifice of the patient's urethra will admit, and introducing it with extreme gentleness, push it very slowly along the canal into the bladder. If it should be arrested, make very gentle pressure against the obstacle for three or four minutes, endeavoring at the same time to distract the patient's attention by a question or two, reassuring him if the instrument causes pain, and it will thus glide onwards, if the obstruction is due to spasmodic contraction of the muscular fibres which surround the canal. If it does not free the obstacle by this manipulation you have probably encountered a stricture, and, by substituting a smaller bougie, and if necessary still another yet smaller, always employing the same extreme gentleness, you will finally pass the stricture. Then, in withdrawing the bougie, by marking the point on its shaft when its shoulder again encounters the obstruction, you will be able to form a judgment as to its length. So that by this mode of examination you will have made a diagnosis: 1st, of the existence of stricture; 2d, of its distance from the orifice; 3d, of its degree of tightness; 4th, as to its sensibility.

I know of no better mode of examining for stricture than this, under these circumstances.

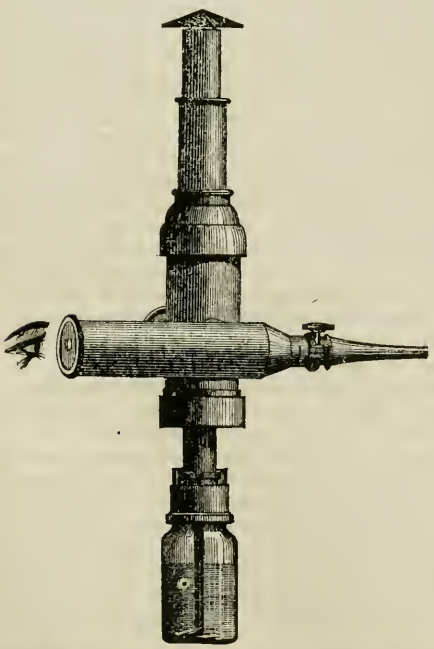
Having thus established a diagnosis, the case is no longer a simple gleet, but a case of stricture; and the appropriate treatment for stricture, of which we will speak hereafter, will afford the best chance of cure for the gleet. For a stricture thus detected for the first time, treatment by dilatation, by means of bougies and steel sounds, will be in the great majority of cases, if properly carried out, entirely competent for a cure. And, when the stricture has disappeared by the use of these means, I can state to you, as our clinical experience, that the gleet will also have been cured. As the rule, this is true; but, unfortunately, there are not unfrequent exceptions to this rule. I say *unfortunately*, after due consideration; inasmuch as these exceptional cases of gleet dependent upon stricture, in which the discharge still persists after the stricture has been entirely removed by proper treatment, are notoriously difficult to cure, and constitute a class of cases very troublesome to both patient and surgeon.

The remedies usually employed, after the use of bougies has failed, are local and constitutional. Amongst the former are injections of sulphate of copper, chloride of zinc, and nitrate of silver; bougies smeared with Guthrie's ointment; blisters to the penis or perinæum. Under the latter head, tincture of sesquichloride of iron, tincture of cantharides, cod-liver-oil, sea-bathing &c., &c. These remedies are applied empirically in consequence of our limited knowledge of the morbid anatomy of the urethral mucous membrane, and the imperfection of the means hitherto employed for its exploration. Hence the unsatisfactory results which so often follow the usual modes of treatment.

When we consider the length and narrowness of the canal lined by this membrane, and its numerous extensions into the ducts of the various glands which pour their secretions into the common outlet, and the complexity of its connexions and sympathies, it is sufficiently obvious why it is so difficult a task to fix the seat and cause of a chronic discharge from the urethra. We require better means of exploring the canal; and it is by improvement in this direction that more accurate physical diagnosis and more successful means of treatment are to be attained. What the application of percussion and

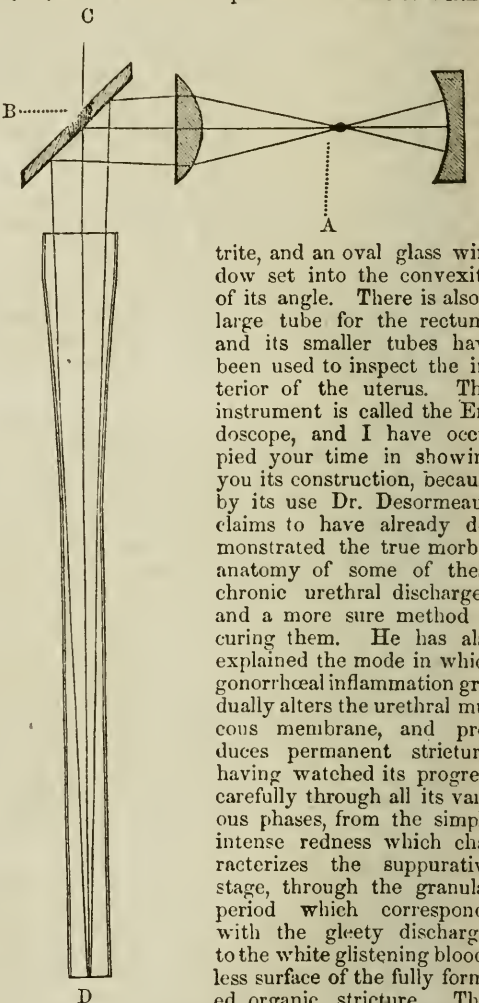
auscultation has accomplished in improving our knowledge of diseases of the chest; what the invention of the ophthalmoscope, and the laryngoscope, and the speculum, has effected in diseases of the eye, the larynx, the vagina, and uterus, we want applied to the urethra. Before Recamier's invention of the speculum uteri a vaginal discharge conveyed to the mind of the physician as uncertain and obscure an idea of the lesion which gave rise to it, as a chronic urethral discharge does at the present time. To-day it requires but moderate skill to determine by the use of the speculum whether the cause of the discharge lies in the walls of the vagina, the neck of the uterus, its cavity, or the cavity of the uterus itself. Many years ago Segalas of Paris, stimulated by Recamier's success, attempted, but in vain, to illuminate the depths of the urethra through a speculum. More recently Desormeaux, a colleague of Civiale at the Necker hospital, acting upon a suggestion of the famous Fresnel, of lighthouse celebrity, as to the management of the light, has perfected an instrument, after some years of study and labor, which promises to be more successful. Through the kindness of Dr. Desormeaux, I enjoyed an opportunity of examining its construction and mode of application in a number of cases last summer. I am satisfied that it is a legitimate addition to our means of exploring the urethra, and that it promises to rank with the ophthalmoscope and laryngoscope. Like these it requires tact and familiarity with its use before it can be adapted to the daily wants of practice; but so also do the finger and the ear before they are useful in practising the touch or auscultation.

The instrument somewhat resembles a dark-lantern, in which the light is collected by means of lenses into a pencil, which, falling upon an inclined mirror, is projected through a hollow tube introduced into the urethra, and illuminates an area of the surface of its lining membrane equal to the diameter of the open extremity of the tube. As the tube is slowly withdrawn the whole length of the urethra may be thus brought under inspection.



The tube introduced separately into the urethra, has its open extremity filled by a wooden plug attached to a stilet. This is withdrawn, and the lantern is afterwards readily attached to its slightly expanded external opening, when the instrument is ready for use. The tube is of polished metal, blackened within to prevent reflection, and the largest size employed is about number 13 of our scale. You will observe that the pencil of light is reflected at a right angle by the inclined mirror, which has a hole in its centre through which the eye of the operator looks into the tube. The source of illumination is thus prevented from interfering with the line of sight; this is the ingenious feature of the instrument suggested by Fresnel.*

For inspecting the cavity of the bladder a catheter is employed, with a short sharp curve like that of a litho-



trite, and an oval glass window set into the convexity of its angle. There is also a large tube for the rectum; and its smaller tubes have been used to inspect the interior of the uterus. This instrument is called the Endoscope, and I have occupied your time in showing you its construction, because by its use Dr. Desormeaux claims to have already demonstrated the true morbid anatomy of some of these chronic urethral discharges, and a more sure method of curing them. He has also explained the mode in which gonorrhœal inflammation gradually alters the urethral mucous membrane, and produces permanent stricture, having watched its progress carefully through all its various phases, from the simple intense redness which characterizes the suppurative stage, through the granular period which corresponds with the gleety discharge, to the white glistening bloodless surface of the fully formed organic stricture. This granular stage of urethral inflammation following gonorrhœa and characteristic of this disease, is the lesion most interesting to us at present, as throwing light upon the pathology and treatment of gleet. Our knowledge of its existence is due entirely to Desormeaux' researches with the Endoscope. It appears that, after gonorrhœal inflammation of a certain degree of intensity and duration, patches of the urethral membrane become studded with minute granulations in particular localities of the canal, which are the sure forerunners of permanent stricture,

* A. The flame of the lamp; B. The hole in the perforated mirror; C. The point where the eye is applied; D. Extremity of tube.

and that more or less gleety discharge is poured out by these granular surfaces, until in the progress of the disease they become converted into the dense non-vascular tissue which constitutes the organic stricture. In the sequence of pathological changes there is an exact analogy between gonorrhœal urethritis and purulent conjunctivitis, and the similar affection, equally well known, of the os uteri. Granular conjunctivitis affects by preference the palpebral conjunctiva of the upper eyelid, and if its progress is uncheeked it leads inevitably to fibrous degeneration of the affected membrane. According to Desormeaux, the same is true of gonorrhœal urethritis. The diseases are equally obstinate, and curable only by similar local applications. In his volume on this subject, published last year in Paris, a case is related in which this granular disease of the urethra had existed eleven years, accompanied by a gleety discharge, and which, in the language of the author, furnishes "a complete picture of the affection." Perhaps, as it contains details also of the mode of treatment by which the disease was effectually cured, I can do no better than introduce here a translation of the case:

"D—— consulted me in the month of October, 1855, for an acute orchitis. He had contracted gonorrhœa in 1846, and had been subject to a slight transparent discharge ever since its cure. Ordinarily, he gave himself little concern about it, but always after rising in the morning, on squeezing the urethra before urinating, he could force out two or three drops of clear, stringy discharge. I noticed also that his stream of urine was smaller than natural, that it was slightly twisted in direction, and lacked projectile force.

"As soon as he recovered from his inflammation of the testicle, the patient, who had become anxious about his difficulty in passing water, submitted to a thorough examination. By the aid of a *bougie à boule*, I discovered, in the bulbous portion of his urethra, a stricture, through which I passed with some difficulty an instrument less than a line in diameter. Its passage caused pain, and the bulbous extremity was bloody when withdrawn. The stricture was more than two-thirds of an inch in length. On introducing the tube of the endoscope and carrying it down to the stricture, I brought in view a red inflamed surface, covered with minute granulations about the size of millet seeds, some larger, some smaller. I had, in fact, under my eye, a granular ulceration, presenting exactly the appearance of the same affection of the neck of the uterus. In withdrawing the tube, the granulations disappeared, and I saw nothing but a red surface, which in its turn passed out of view, and as far as the meatus the remainder of the urethral mucous membrane was perfectly healthy.

"The discovery of this lesion seemed to me to explain fully the whole pathological history of the case; for it was easy to understand that a continuous discharge could be kept up by a granular ulceration, similar to those we see daily on the palpebral conjunctiva and uterine neck, and which are so notoriously persistent and difficult of cure. The ulceration explained at the same time the chronic thickening of the urethral mucous membrane, causing the stricture I had just made out. I could also see clearly, by the persistence of this granular surface, why, contrary to the testimony of most writers on this subject, a chronic discharge from the urethra continues, in some cases, after the thorough dilatation of the stricture to which it is attributed; or, when temporarily checked during treatment, reappears as soon as the use of instruments has been discontinued, as I have seen so often happen.

"I decided finally to treat this lesion of the urethra by the same means employed in similar granular ulcerations of the os uteri, and, in order to verify the relation of cause and effect probably existing between the ulceration and the stricture, I concluded to withhold the use of bougies for the latter.

"The endoscope afforded me the means of applying remedies to the diseased surface exactly as they are applied to the os uteri at the bottom of the speculum. I made use of cauterization, by a concentrated solution of nitrate of silver, carried through the tube, and was able to see distinctly the immediate effect produced upon the granular surface. These cauterizations were repeated every three or four days, the patient, in the interval, using injections in the urethra, of a decoction of rose leaves. Although the strength of the solution of the nitrate of silver was one part of the salt to three parts of water, the pain produced by its application was slight.

"This treatment, commenced on the 5th of December, 1855, had been carried out more than a month, when, on the 25th of January, 1856, without anticipating such an occurrence, I found that the tube of the endoscope could be passed through into the bladder; it had traversed the seat of the stricture without communicating the sensation as of having freed any obstacle, although its diameter was nearly three lines, and it fairly distended the anterior portion of the canal. It was evident that the stricture had disappeared, without any other treatment than that applied to the granular surface.

"I was thus enabled to examine the whole extent of the urethral mucous membrane, from the neck of the bladder forwards. The prostatic portion was slightly red; this redness increased in the membranous portion, and, towards its union with the bulbous expansion of the spongy portion, the ulcerated surface was recognised, its granulations being now hardly visible. The patient asserted that for some days previously he had passed as large a stream as in early life. Three additional cauterizations removed all remaining traces of the granulations; after this the patient continued his urethral injections for ten days, and then discontinued all treatment.

"A few days later, the discharge had entirely disappeared, and the *bougie à boule* traversed the whole length of the canal without encountering any obstacle. The endoscope showed but a slight redness remaining at the seat of the disease, and it was obvious that the ulceration had been entirely cured, and also that the stricture had disappeared under the influence solely of the treatment applied to the granular ulceration.

"I have had this patient under observation for eight years, and he has had no return of his disease." *

It is apparent, then, if M. Desormeaux's observations and deductions are confirmed by the experience of other observers, that his instrument has already added to our exact knowledge of the pathology of gleet and stricture, and that it also affords us more certain means of applying remedies to the cure of these affections.

I am able, from a somewhat limited experience, to speak favorably as to its practical utility. By the aid of my friend, Dr. Gouley, who has acquired much facility in the use of the endoscope, I have satisfied myself of the existence of this granular condition of the urethra, and that its presence explains the persistence of a gleety discharge after a fair trial of bougies and sounds, as proved by its cure after the careful application of solution of nitrate of silver to the granular surface.

Desormeaux's instrument has been modified and improved in some respects by Cruise of Dublin, who testi-

* De l'Endoscope et de ses applications au diagnostic et au traitement des affections de l'Urethre et de la Vessie: Leçons faites à l'Hôpital Necker, par A. J. Desormeaux, chirurgien de l'Hôpital Necker de Paris, 1865, p. 48.

fies as to its practical value in a paper upon the endoscope and its application, in a recent number of the Dublin Quarterly Journal of Medicine.

Of some other forms of chronic urethral discharge, depending upon a morbid condition of the more purely genital organs, as the ejaculatory ducts, seminal vesicles, and prostate gland, including that described under the somewhat fanciful name of "Prostatorrhœa," I shall take occasion to speak hereafter.

A CASE OF VERSION BY EXTERNAL MANIPULATION.

By THOMAS B. STIRLING, M.D.,

RESIDENT PHYSICIAN TO THE NEW YORK LYING-IN ASYLUM.

Honora Fraley, was born in Ireland; is 28 years of age, of medium height, sanguine temperament, fair complexion, well formed, and presents the appearance of rugged health, which, she says, she has always enjoyed. She has been married six years, and during that time has suffered one miscarriage four months after marriage, and has borne four children, the last of which alone was born alive.

She was admitted to the New York Lying-in Asylum, December 27th, 1865. In consequence of some information derived from the nurse, I deemed it necessary to obtain from the patient a careful history of her case. She stated that she expected to be confined every day, and that she was very much exercised in mind with regard to the result, for she had had already three cross-births, and that she felt very much the same way as she had done previous to her other confinements. When asked what she meant by that, she replied that the "children lay wrong; they lay cross-wise, and that all three had to be turned in the womb, the attendant introducing his hand for that purpose, and that they were born by the feet; that the operation in each case took very long—over two hours—(of course an exaggeration), and that she thought the children died by hanging a long time by the head." She further stated that "in the first confinement she had to keep her bed for three months, and did not regain her strength for six months more. She had not been quite so ill with the other two, but still had been quite prostrated in both instances." Various interrogations were put to her with the view of testing her intelligence and reliability, and it is believed that the preceding statement, with the following additional particulars, may be looked upon as substantially correct.

All three confinements took place in London, and within the last four years.

In the first confinement—date probably August, 1861—she was attended by Dr. Dickerson, parish physician of Chelsea; the patient then living in Orford Cottage, No. 4 Orford street, her husband being employed as a laborer by Mr. Kelk, builder.

In the second confinement—date probably December, 1863—she was attended by a midwife, Mrs. Godwin, who also, it appears, performed podalic version. A physician was called in by the midwife in the crisis of the case, but he did not arrive until after the birth of the dead child; his name was never known to the patient.

In the third confinement—date Feb. 16, 1865—she was attended by Dr. Braithway (Braithwaite?), Lambeth Walk, near Westminster. She became again pregnant in March, 1865, and came to New York in August last.

In consequence of the interest excited in her case, a careful examination of her condition was then made, Dec. 27th, four days before her confinement, both externally and per vaginam. The child was readily found to be lying in utero, in an unmistakably transverse position, the head being on the left side, and the feet on the right, with the back arching towards the fundus uteri. No signs of approaching labor could be detected per vaginam, and no presenting part could be discovered. The cervix had still some length, and the os was not patulous in any appreciable degree.

An attempt was made at this time to turn the fœtus by external manipulation, and the ease with which this was quickly accomplished, excited in me no little surprise, as it was the first time I had ever attempted such a procedure. It was first suggested to me by a lecture of Prof. T. G. Thomas, heard a few days before.

The head of the child was carried or pushed downwards towards the pubes, and was readily pressed into the pelvic cavity, and could be retained there by holding it in position. It was thus left, and the patient was not seen again until the following Sunday. On this day (December 31st), at half-past 9 A.M., the attention of the resident physician was called to this patient by the nurse. She had been unable to remain in bed during the previous night, from the recurrence of pains, and she was thought to be in labor. Examination showed this to be the fact; the os uteri was completely dilated; the membranes were protruding and filling the vagina; they were still unruptured, and were of the usual wedge-like form when the breech presents. No presenting part could be made out; nothing being found of greater consistency than the bag of waters.

By external examination, the child was distinctly made out to be lying in a transverse position, the head being now on the *right side* of the abdomen, so that the fœtus had shifted its position since it was first observed, and had already made one half of one complete revolution in utero. Fearing the rupture of the membranes before version could be produced, the patient was kept scrupulously on her back until the lying-in chamber could be prepared for her reception. After an interval of half an hour I again visited her, and everything had remained as before; the pains being slight, and recurring only at long intervals.

An attempt at version was now made by pushing the head in a downward direction, towards the pelvic cavity, and at the same time favoring this movement by pushing the nates in an opposite direction so as to cause the head to retrace the quarter revolution which it had spontaneously made. This manœuvre not succeeding, it was next tried to move the head in the contrary direction, and progress in this was at once noticed.

This movement was steadily but cautiously followed up in the intervals of the pains, for the external manipulations had the effect of making these both more frequent and more severe, so as to cause some apprehension of the membranes rupturing before the version could be completed. Persevering in this moderate and cautious course for about an hour and a half, I had the satisfaction of following the head completely round the abdomen until it was again fairly lodged in the left iliac region.

It was now three-quarters past 11 A.M., and I was compelled to leave the patient in charge of the nurse for half an hour, to keep an appointment, taking pains to instruct her how to retain the head in the favorable position gained, until my return. When I came back, I found that, notwithstanding my cautions, the head had been permitted to go back in its course an entire quarter of a revolution, so that it now occupied precisely the position in which it had been found four days before.

At half-past 2 P.M., the operation of version was again resumed, and the advanced position was regained with

even greater facility, and the head went readily beyond, so as to be brought under the pubes, and easily pushed into the superior strait.

The nurse was directed to hold the head in this position, and an examination was made per vaginam The bony tissue of the head could, with some care, be made out, quite high, and in front, under the pubic arch ; the sutures were distinctly recognisable.

The propriety was here considered of rupturing the membranes at this time, so as to fix the head in the strait, or whether it would be better to trust to the nurse to hold it there until nature should complete the labor. The pains being slight, and it being very desirable to save the life of the child if possible, it was determined to avoid the danger arising from too great and protracted compression of the head, and to leave the membranes intact as long as possible. It was thought that a very little attention on the part of the nurse would enable her to hold the head in its now favorable position; and indeed she succeeded perfectly in this to the end.

At 3 P.M., the patient was again visited; the pains had continued slight and unfrequent; the head seemed to be becoming slowly engaged in the superior strait, but required still to be held in position, as it had shown a tendency to recede again.

At 5 P.M. there was a sudden call for the doctor, for in consequence of a pain the membranes had ruptured, and something had passed out which was thought by the patient to be the head of the child Examination showed that a portion of the amnion, containing fluid, in the form of a filled bladder, was lying in the bed, but still attached within the uterus by a long membranous strip. Passing the hand within the vagina, a mass of prolapsed cord was encountered, pulsating strongly, but jammed between the head and the rectum. The patient was immediately placed upon her face and knees, in the position recommended by Dr. Thomas in such an emergency, and then the pendent bladder of fluid was removed. An endeavor was now made to return the cord to the uterus. This was not at first successful, but by maintaining the patient in this position for about a quarter of an hour, the head receded from its impaction in the strait, the hand could be passed into the vagina, and up to the mouth of the uterus, and the cord successfully carried over the head and retained there. The patient was kept in this position some time, lest the cord should return; but the pains soon increased, and the head advanced steadily in the strait, and when there seemed to be no further risk of the cord returning, the patient was placed upon her left side.

The labor advancing rapidly, and everything being favorable, it was ventured, after a little while, to place her on her back in the usual obstetric position.

At half-past 6 P.M., careful examination was now made, and the position was not considered most favorable, being almost transverse—the right ear being felt distinctly in the median line under the symphysis. With some manipulation, however, the vertex was brought down and into more favorable relations to the pubic arch, and by this the labor was very much hastened. The delivery was completed at 6.40 P.M. The child seemed lifeless, paralysed as it were, rather than asphyxiated. It was very pale and flaccid in body and limbs. The cord was beating strongly, however, the bones of the head quite loose, and the caput succedaneum well marked and on the right side of the head, and in *front of the ear*, showing how the head had been engaged in the pelvic strait. It required full fifteen minutes' effort to establish regular respiration even feebly, but the cord never ceased to beat markedly. It was finally cut before it ceased beating, and before respiration was fully established, and without tying it, but it refused to bleed even when the child was placed in a tepid bath. Finally, respiration was fully though feebly established, and at the end of a few days it showed a very vigorous vitality. It nursed strongly and grew rapidly, and the mother convalesced unusually well, having no drawback whatever. The child's weight at birth was eight and a half pounds, and the placenta two and a quarter pounds. It is now four weeks old, is doing well, and has recovered from the effects of vaccination, which was performed at the tenth day.

VESICO-VAGINAL FISTULA,

OF TWENTY-THREE YEARS' STANDING, SUCCESSFULLY OPERATED UPON.

By E. P. BENNETT, M.D.,

DANBURY, CONN.

The lady who was the subject of this paper was 48 years of age, and naturally of a remarkably good constitution. Twenty-three years ago she was delivered of her second and last child. The labor was rather protracted, and forceps were made use of. From this date she suffered from incontinence of urine, and all the ills which flow from this terrible affliction. She was from time to time under the care of different physicians for her urinary troubles, but, strange to say, for twenty-three long terrible years, no one had ever discovered or suspected her real trouble. Exhausted and discouraged, she finally called upon me about a month ago, and at the first visit I ascertained the nature of her difficulty, and was able to promise her speedy relief. Upon examination I found a hole at the neck of the bladder about an inch in length, extending transversely as though the neck of the organ had been torn off. Out of this opening, a very vascular fungus projected, about the size of a walnut. This fungus would occasionally fill up the rent in the bladder, when she would suffer terrible bearing-down pains, and would experience great difficulty in urination. The vagina and vulva were swollen and tender, and the urine was loaded with muco-purulent matter. Her strength and appetite having greatly failed, she was in every respect in a miserable plight, and an object of the deepest commiseration.

I immediately confined her to her bed, washed out the parts with new milk and water and flax-seed tea, and in a few days with her consent I proceeded to operate. I was ably assisted by my son, Dr. W. C. Bennett, and by my brother, Dr. F. N. Bennett, of Orange, New Jersey. The parts appeared to be tied down by adhesions to the inside of the pubes, and great difficulty was experienced in bringing them into view. To overcome the difficulty I introduced a straight silver catheter into the sound part of the urethra, and then into the opening of the bladder, and by this I was enabled, by the aid of an assistant, to lift the parts up, and bring them fairly into view. I then removed the fungus, and after a lengthened period I succeeded in so freshening the edges of the rent, as to venture to bring the opening together, which I did with seven silver sutures. It was a long and tedious operation, as the parts, from continued inflammation, had become so exceedingly vascular, that every touch with the knife deluged the parts with blood, and delayed further proceeding until the hæmorrhage abated. I used in this operation no clamp or button, but simply the silver suture. On the tenth day I removed the stitches, and to my inexpressible delight

the success was complete; every part had firmly united, and not a single drop of urine has since escaped.

The catheter was continued for a few days, then removed and used occasionally. She can now retain her water perfectly, and what is still more remarkable, she has complete power to empty the bladder at will. I supposed that after the bladder had been so long contracted and its walls so thickened, it would be quite a long time before it would be capable of containing much fluid or of expelling it with facility, but in this I am happily disappointed. After so many years of such an amount of suffering, she can hardily realize that she is again restored to health and society.

This is my second operation of this kind, both of them being successful. There is one fact in regard to this case which is both astonishing and humiliating, and that is this—that for twenty-three years she had been attended for weeks and months together by regularly educated practitioners, as well as quacks, and no one has ever so much as hinted at or suspected the nature of the case, when all the symptoms were such that it seems hardly possible that it could have been mistaken by the merest tyro in the healing art.

Original Lectures.

ON CHOLERA.

By A. CLARK, M.D.

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

Lecture II.

The Pathological Anatomy of Cholera (continued). *Post-mortem appearances of Kidneys, Spleen, Lungs, and Heart. The Symptoms of the Disease—Diarrhœa Vomiting, Cramps, Suppression of Urine, Change in Voice, Collapse, etc.*

I will proceed with the examination of the lesions that are noticed in those who die of Asiatic cholera.

The *kidneys* come next to be considered. In these there are no very marked changes. There is a certain amount of increased vascularity, chiefly referred to the veins and the portions of these organs that are nearest the calices; and in general there is a pretty free exfoliation of the epithelial lining of the pelvis and tubes that open into this cavity. In the typhoid period, or stage of reaction, an appearance has been observed by Virchow (and certain other pathologists), which he regards as analogous to that which attends Bright's disease. You will soon learn that there is a marked disturbance in the secretion of these organs; and, from the nature of these disturbances, you would naturally enough expect that there would be some resemblance between the kidney lesions in the two diseases, if the observation be limited to the early stage of the chronic affection.

The *spleen* has not been noticed to undergo any very marked alteration; it is often described as flabby; it is described as enlarged in regions where intermittent fever prevails; but such enlargement is referred, not to cholera, but to previous miasmatic influences. The *bladder* is found almost uniformly contracted and nearly empty, perhaps in a majority of cases actually empty; and in those that contain any fluid, there is only a drachm or two, and that is rarely healthy urine, but almost always a milky fluid, sometimes reported as pus. Whether it is or is not, can be readily determined by the microscope; it is highly probable that the purulent appearance is given to the fluid by exfoliated epithelium from the kidneys, or the bladder itself, which is mingled with it. This completes the consideration of those organs found below the diaphragm likely to be involved in this disease.

If we turn now to the contents of the thorax, we shall find some important facts bearing on the theory of cholera. In passing, I may say that the examination of the *larynx* shows in a certain proportion of the cases a degree of vascularity regarded as unnatural; that the vocal chords appear in general to be loose and flabby, and rarely a little swollen from œdema. This, however, is not, probably, the chief cause of the feeble voice and aphonia, of which I shall have occasion to speak directly.

In view of the new theory of the cholera collapse just now proposed by Prof. George Johnson, well known in this country through his excellent book on the Diseases of the Kidneys, it will be desirable to acquire as definite an idea as possible of the quantity of blood found in the *lungs* of those who die in this stage of the disease. He holds that the lungs, under such circumstances, contain much less than the usual quantity of blood, and says, "With respect to this extremely anæmic condition * * * there is an entire agreement among those authors who have most accurately described the *post-mortem* appearances. There is something surprising, as Briquet and Mignot observe, in the contrast between the almost constant occurrence of this extremely anæmic condition of the lung, from which scarcely a few drops of blood flow when the tissue is cut, and the hyperæmia of most of the other viscera. There is a remarkable contrast, too, between this anæmia of the lung, when death has occurred during collapse, and the great engorgement of the lung which is almost invariably found when death occurs in the febrile stage which often follows reaction." He refers to Dr. Parkes as stating in substance that "the tissue of the lungs is, in most cases, of a pale color, dense in texture, and contains less than the usual amount of blood and air."

Drs. Baly and Gull give, on the condition of the lungs, a resumé of the reports they have received from the physicians of England, and quote four other authorities, among whom are Briquet and Mignot. It is but fair to complete the extract Dr. Johnson has made from these authors, by adding what follows their reference to the contrast between the state of the lungs and that of other viscera—"The posterior parts [of the lungs] were however frequently the seat of a certain degree of engorgement; this was noted in sixteen cases, but in only six was it well marked." "In two there was serous infiltration, accompanied by extreme congestion of the posterior parts." Virchow is quoted as saying: "On the removal of the sternum, the lungs, in general, collapse to the spine, except when there existed bronchial catarrh or œdema. The lower lobes were for the most part much congested." Reinhardt and Leubuscher report that "the lungs were found, for the most part, much contracted, * * * the pulmonary tissue was in general dry and anæmic, especially in the upper lobes; on section, a small quantity of blood oozed from the larger veins. The lower lobes were, in general, full of dark blood." Leudet states: "The lungs were commonly healthy," there was "frequently hypostatic congestion."

The summary of the reports made to Drs. Baly and Gull, they give as follows: "In the majority of cases fatal in the algid stage, no other morbid change existed than the engorgement of the lower and posterior parts of the lungs with dark blood. In some instances this was so complete as to cause portions of the pulmonary tissue to sink in water. The anterior and superior

parts were dryer than natural. * * * In certain cases, the pulmonary tissue throughout was full of dark blood."

There are few more competent observers than Drs. Pennock and Gerhard. In their report of cases occurring in the first epidemic in Paris, the autopsies being made under the direction of some of the best physicians of that city, they do not appear to have been impressed with the idea that the lungs were so extremely anæmic. They speak of these organs sometimes as "light;" but in their summary of thirty-four examinations, they do not refer even to this quality, but lead us to the conviction that they found nothing particularly noteworthy in the quantity of blood in the lungs. Indeed I may say, that in a somewhat critical examination of the reports of the *post-mortem* examinations of many physicians intrusted with cholera hospitals, the possibility of "extreme anæmia" of the lungs in the algid stage had not occurred to my mind till I saw the papers of Dr. Johnson. I will not assume that he has too hastily adopted this conclusion, but will ask that the question be submitted to the investigation which his views would naturally suggest.

In general, the authors I have consulted describe the lungs as healthy. In a few they are the seat of little apoplectic effusions; emphysema of both varieties is sometimes found; and in those who die in the period of reaction or typhoid stage, they are occasionally found to be the seat of congestion and hepatization. Pneumonia, in a greater or less degree, is a common occurrence in this stage. It is noticed by almost all observers that a very small proportion of those who die of cholera show tubercles in their lungs. This is a fact interesting in one respect; it would teach us that persons who are affected with tubercular consumption are at least no more liable to this disease than those who possess healthy lungs. Ecchymotic spots are sometimes noticed under the *pleura*, otherwise this membrane is found almost uniformly healthy, except in the period of reaction, and then there are noticed upon it spots of lymphy exudation in certain of the cases.

The *heart* does not in itself seem to undergo any very marked changes; it usually has rather a pale appearance, sometimes, however, darkened by the slow return from it of the venous blood, and sometimes its lining membrane is dark from imbibition; it is occasionally a little flabby, but for the most part presents what may be regarded as a healthy appearance. Its contents will interest us more than the organ itself. It is often found closely contracted in its left cavities, the right being filled with blood; sometimes all the cavities contain blood, but generally when all contain blood, the right auricle and right ventricle contain more than the cavities of the other side. Here, again, Dr. Johnson makes a point in favor of his theory, assuming, as he undoubtedly may, that in the great majority of cases in which death has occurred in the stage of collapse, the right cavities are filled, and the left empty, or nearly so, and the ventricle firmly contracted, and he adds, that the pulmonary arteries are also filled with blood. He associates these facts with the anæmic condition of the lungs, and collates both with certain symptoms to be hereafter described, and thinks he finds reason for asserting that there is a formidable obstruction to the progress of the blood from the right heart into the lungs, produced by an unnatural contraction of the branches of the pulmonary artery. The *blood* itself is an object of particular attention. It is thick, and is compared frequently with molasses; it undergoes coagulation but imperfectly. In quite a large proportion of cases, the blood in the heart and in the large veins is not coagulated at all. Pennock and Gerhard report that in thirty-four examinations, they found the blood entirely liquid in the heart in eleven; that it was fluid with bloody coagula intermingled in twenty-three; not firmly coagulated in any. It would seem then pretty clear, inasmuch as other observations correspond strictly enough with these, that the blood has undergone a change which is not compatible with full and ready coagulation. In this respect it resembles the blood of those who die from typhoid fever. The blood is to be found in the veins more than in the arteries. The arteries connected with the heart are frequently empty when the veins are full. Pennock and Gerhard found some serum in the pericardium in sixteen of their cases, or in nearly one half.

This may be considered as completing the enumeration of the pathological changes that belong to cholera. It is clear that all of them occur in the progress of the disease; they are consequences, therefore, and not causes. As consequences they are immediate, or more or less remote, one depending on another. But the one cause of the disease lies behind them all. It is probable that the morbific poison for a limited time circulates in the blood, before its symptomatic manifestation, and that single fact implies a change in this fluid, but not a change that is sensible to ordinary examination. Now we turn to the phenomena appreciable during life.

The first fact to be noticed in enumerating the symptoms of this disease is, that there is in the great majority of cases a diarrhœa, continuing for a certain number of hours, or days, or weeks, varying in severity in different cases, varying in different periods of an epidemic, and not to be distinguished from diarrhœa that does not lead to cholera. During the prevalence of this disease large numbers of people are affected with looseness of the bowels, and in a certain proportion of these the disorder culminates in cholera; in a large number it has no such termination. The diarrhœa, then, may or may not be considered a part of the phenomena of cholera. For our purposes at present we may say it is a part of the disease. The diarrhœa, then, that is to lead to cholera is either painless, or attended with colics, or with gurgling or movements of wind in the bowels. You are not to infer that it is always a painless diarrhœa; it is far from being so, colics are not an unfrequent attendant. The diarrhœa, however, is what is usually called "bilious;" the stools are ordinarily yellow, and usually retain this color until certain phenomena occur, that I will refer to in a moment. The number of discharges that precede the exhibition of the cholera symptoms will vary immensely in different persons; sometimes there will be no more than two or three, sometimes three or four or more a day for some weeks; at other times twenty daily, for a day or two, and still there is nothing characteristic in the discharges. At length a time comes when the diarrhœa, if it has been mild, becomes more violent. Then, or soon after that, the discharges are changed in appearance. From being yellow, or appearing to contain bile, they now become of an opaline appearance; they are called serous, or "rice-water" discharges; and soon after, or sometimes simultaneously with the occurrence of this more violent diarrhœa, there are cramps and vomiting. It is not easy to give a definition of disease, but the nearest we can approach to a definition of cholera is to say that it is characterized by purging, vomiting, and cramps, and by a prostration or collapse, which is only imperfectly accounted for by the evacuations which precede it. The purging is almost constant; the vomiting is not absolutely so, nor are the cramps; still, I do not know that a better definition can be made. Including the initiatory diarrhœa, the disease readily divides itself into four stages; the stage of simple diarrhœa; the stage of violent diarrhœa, with vomiting and cramps; the stage of col-

lapse; and finally, the period or stage of reaction, or typhoid stage. The second and third stages are not, however, distinctly separated, for while the symptoms of the second often exist for a certain time before those of the third occur, the purging, vomiting, and cramps, one or all of them, are usually prolonged far into the collapse. With reference to the duration of the bilious diarrhœa, I have here the facts, as they appeared in twelve cases (Pennock and Gerhard), and will read them in the order in which they are recorded. The cases occurred in the beginning of an epidemic, when the diarrhœa is likely to be shorter than at a later period. In the first case it continued two and a half hours—ten evacuations. In the second case, the diarrhœa lasted two days before the cholera was established. In the third case there was no diarrhœa until after the cramps began, and after this there were only four evacuations up to the period of collapse. In the next case, again, there were no evacuations until the cramps began; after this the diarrhœa was severe. In the next case it lasted ten hours; in the next, two hours; in the next, two hours; the next, thirty-eight hours; the next, thirty hours; in the next case, thirty six hours; in the next, two and a half days; and in the next, three weeks. Doctor Buell, in summing up the cases treated in one of the New York hospitals, in 1854, remarks, that of 469, the average duration of the diarrhœa was three days and six hours.

About the time the cramps and the vomiting occur, two other phenomena are noticed: the suspension of the urinary secretion, and a marked change in the voice. In these same cases to which I have just referred, suppression of the urine was noticed mostly at the time when the diarrhœa became violent; in eight, suppression occurred at this period; the urine was suppressed, and afterwards secreted in one case; there was no suppression of urine in three. And this, I suppose, may represent to you, pretty truthfully, the rate of frequency with which this symptom will be present, and the time when it is likely to be first noticed. With reference to the voice in these twelve cases, it became feeble from the first of the diarrhœa in one; it became feeble at the commencement of the collapse in eight; reduced to whisper in the deeper collapse in several; in one, it became almost extinct at the first of the collapse, and more distinct afterwards.

The vomiting is usually at the first merely the contents of the stomach, and frequently contains food; sometimes food that has remained undigested for many hours. Many times undigested food is found in the stomach after death, notwithstanding there has been prolonged vomiting. Soon, if it is persistent, the vomit will be like the discharges that occur in the violent purging, resembling rice-water, or a thin fluid of a greenish color; or sometimes of a dark green hue. It varies in its appearance, then, under different circumstances. It is often tasteless, while frequently it has a bitter taste. In two of the cases just referred to there was no vomiting during the whole progress of the affection. The time of its beginning in the other cases may be thus summed up: Began with the diarrhœa and cramps, second stage, in six cases; began one and two hours before the cramps in two cases; was one of the first symptoms, associated with diarrhœa and cramps, in two cases. In two instances, it was very copious, greatly exceeding the fluids that were swallowed and in one recorded as basinfuls of transparent fluid containing flocculi.

The cramps, as you have already learned, are associated with this more violent stage of the disease, beginning usually with or soon after the transition from the more simple stage of diarrhœa to what may be denominated choleraic. They begin in the inferior extremities in the greater number, and usually pretty soon pass to the whole body; in a few they are confined to the inferior extremities entirely; in a still smaller number they are present only in the legs—that is, in the part of the lower extremities below the knees. They have sometimes been known to begin in the toes and fingers together, and then spread over the whole body. Sometimes they become at once general. They usually continue during nearly the whole of the period of the serous diarrhœa; they frequently cease as the period of collapse advances. In a considerable number these cramps are light, and do not distress the patient seriously; in some cases they are terribly painful. The cramps, the sense of weakness, and a certain burning sensation which I shall refer to pretty soon, a burning thirst and sense of oppression at the epigastrium, may be regarded as the chief sources of suffering in persons who are in the collapse of this disease.

Now, then, what symptoms announce the collapse in cholera? It does not always begin with the aggravation of the diarrhœa; generally it follows this, giving an interval which varies only by hours. The collapse of cholera is chiefly indicated by these associated facts: a very marked feebleness of the pulse at the wrist, perhaps pulselessness, while the heart is beating with considerable force; coldness and lividness of the surface in parts or over the whole of the body; a sense of prostration and feebleness not inconsistent with considerable muscular strength. These appear to be its distinguishing features, while other symptoms, to be referred to soon, concur with them. The coldness usually begins on the nose and tongue; the feet, the hands, the legs, and the face become cold in succession; the arms and then the thighs, then the surface of the breast, then the forehead, then the chin, and then other parts as the disease advances. It is very common, however, to notice that certain portions of the body do not feel the influence that produces the cold; the surface of the abdomen is often warm to the hand, as is the back, probably from the protection of the bed. The lividness is noticed to occur in very nearly the same order. It is first noticed upon the lips, then upon the whole face, and under the nails of the toes and hands; then on the surface of the breast, and then over the whole body. With this coldness and lividness is commonly found a considerable degree of moisture upon the surface; a cold sweat, notwithstanding there are such vast discharges of the fluid matters of the body from the bowels; in a few, the surface is dry. The breath is frequently cold.

The pulse, during this period of collapse, is not so materially affected in frequency as you might suppose. It does sometimes reach one hundred and thirty in the minute, but frequently it is no higher than eighty-five or ninety; and it is noticeable that if the pulsations are frequent at the beginning of the collapse, they are apt to grow less frequent as the disease advances towards death.

The respiration is frequent, and occasionally there is a good deal of dyspnœa. I am not sure whether it was from this fact that the disease received the suffix *asphyxia*, or whether it was from the blueness that is upon the surface, or whether the word was used in its etymological significance, meaning pulselessness. The respiration is often nearly double the usual frequency. The normal respiration is, you will remember, from sixteen to twenty—perhaps eighteen—per minute. In half a dozen cases of collapse it was counted as follows: thirty-four, thirty-four, twenty-eight, twenty-eight, thirty-two, and thirty-eight. There is another fact relating to the respiration—it is scarcely at all abdomi-

nal, but almost entirely costal; or, as the phrase is, high.

Thirst is often a distressing symptom; this would seem natural, in view of the quantity of the fluid that is sometimes discharged from the body. The patient will drink almost without limit if permitted to do so; frequently he drinks and rejects the fluid at once; occasionally he drinks, if the drink be cold, and he will retain it. At the epigastrium there is a sense of great distress, many times; occasionally it is a burning sensation; sometimes it is simply a pain; sometimes it is a sensation of weight.

I should have remarked, perhaps, a little earlier, that while the whole body may be cold, while the arms particularly are cold, the patient very generally thrusts his arms out of the bed-clothes, because he feels a distressing sense of burning in them; he gets relief many times by the application of cold water. This burning sensation, while really the temperature is considerably below the normal standard for the part, though not a constant, is still a striking feature of the disease.

As this collapse advances, the expression of the face becomes cadaveric, and as the patient lies in bed he might be mistaken for a corpse in everything but that he is seen to breathe; the hands and the feet become shrivelled, particularly the palmar surface of the toes and fingers. The sense of prostration in many of these patients is extreme. In some of them the skin becomes insensible to pinching or pricking; in a larger number the sensation is preserved. Pennock and Gerhard noticed that the skin had lost its elasticity in the collapse. Pinching it up on the neck between the thumb and finger, they noted the rapidity with which it replaced itself upon the surface. They state that in every case of true cholera on thus pinching up the skin, it falls back to its natural position very slowly; and that in cases that imitate cholera, and are not true cholera, it retains its elasticity and falls back quickly to its place.

The intellect is usually unimpaired, and though the patient may have lost his voice, so that he can speak only in a whisper, or even feels a sense of exhaustion that induces him to make no reply when spoken too, yet in most of these cases the intellect is in full force. In some, however, as you have already learned, there is a good deal of congestion, and even serous effusion, within the cerebral cavity. In such cases there is often somnolence, from which it is difficult to arouse the patient; and in a small number actual coma. Some of the patients complain of tinnitus aurium. In a large proportion of cases, the abdomen in cholera is retracted; in a few instances there is a gaseous accumulation in the intestines that amounts to tympanites.

In deep collapse there is entire loss of pulse at the wrist; gradual weakening of the heart-beats, as perceived by the hand or ear applied over the precordial region; the features becoming entirely immovable; the eye partly closed; in a few the tracheal râles last sometimes for two or three hours before death comes; aphonia is absolute; vomiting and purging cease at this period, as a rule; indeed, may have ceased earlier—although in some the purging will continue to the very end; the cramps have ceased; the coldness of the face and arms is extreme; and in some there is delirium, that is, the mind wanders. Thus, then, we arrive at the close of this formidable array of symptoms. And now the question comes, what has produced all this commotion in the system?

But before I attempt to answer that question, I will return to one point that I left unfinished. Perhaps one of the most practical questions to be answered, is whether there is always a preliminary diarrhœa. That subject has been the occasion of some controversy. In describing the cholera as it was seen by himself in a cholera hospital in Brooklyn, Dr. Hutchinson enumerated six cases in which he thought he was authorized to say there was no preliminary diarrhœa. The following is a synopsis of the cases. In one the first symptoms were vomiting and purging, no cramps occurring during the disease; death occurred in sixty-six hours. In this case it is claimed there was no preliminary diarrhœa, because the vomiting and purging occurred at the same time. In the second, vomiting and purging were the first symptoms, and occurred together, the cramps occurring half an hour later; death took place twenty-seven hours after the initiatory symptoms. The stools were thin and watery. In the third case there were vomiting, purging, and cramps in the stomach only, these three features of the disease concurring; the patient recovered. In the fourth case there were vomiting and purging at five o'clock, and cramps at six o'clock; death occurred thirty-five hours afterwards. In the fifth case vomiting and purging commenced together at eight o'clock, and at nine the cramps; death occurring twenty-five hours afterwards. In the sixth case there were vomiting and purging at five o'clock, and cramps at six.

Now, Dr McLaughlin, of London, says of these cases two things. He says, in the first place, that the representation which patients bring with them—even the representations of relatives of patients—cannot be trusted under these circumstances; that while cholera is prevailing, persons who have had diarrhœa for days flatly deny the fact, and compel their companions to support them in the falsehood; and he thinks Dr. Hutchinson must have been thus misled. I can easily understand this. Dr. Trask, in his history of the epidemic of cholera in the poor-house at White Plains, says he early gave the inmates instructions to report to him the first appearance of diarrhœa; and he repeated that instruction: and yet, over and over again, he found that the persons affected by cholera had had diarrhœa a variable time, and not only did not report it, but forbade their friends reporting them. This is the history of almost all institutions of this kind. It is common in penitentiaries, that while the patients are instructed to send information on the first sign of diarrhœa, that they wait, having diarrhœa, many of them, until cholera is fairly declared. It might, then, well enough happen that Dr. Hutchinson did not get correct information on this point, however earnest and honest he might be in the endeavor. But further, Dr. McLaughlin says it was not fair to say there was no preliminary diarrhœa, because the vomiting and purging occurred, in one case, half an hour before the cramps, and in three others an hour before. He says these must be thrown ont of the class of cases in which it is claimed that preliminary diarrhœa does not occur. That is pretty close work. The diarrhœa occurred with the vomiting, and lasted half an hour, and one hour before the cramps occurred; and Dr. McLaughlin claims that the cramps constitute the cholera, or rather that the occurrence of cramps is the essential fact. Then he states in the New York *Medical Journal* for January, 1856, that he has made the most extensive inquiries in London; that the medical staff of seven of the largest hospitals there and thirty-six medical men of the "Popular Union" (where all cases have been carefully recorded for five years), certify that, in their observation, no instance of cholera has occurred without the preliminary diarrhœa. He further appeals to the Report of the Registrar-General for 1853, and to the *Medical Times* of that year; and from all these sources claims authority for saying that every case that occurred in all London at that time was preceded by diarrhœa. In another paper on the same subject he states

that he has collected the largest observations possible of the several epidemics that have visited London, and he has come to the same result—that there has been no instance in that city, in the range of his inquiries, that can be regarded as cholera, without a preliminary diarrhœa; and this statement embraces the year 1849. Dr. Hutchinson replies that his cases were carefully studied, honestly reported, and that a revision of them discloses no error.

I find in another book, and wholly unconnected with this controversy, in the deliberations of a learned society, this statement regarding the cholera of 1849, in London (it was part of a discussion in the Medical and Surgical, or Medico-Chirurgical Society): "Dr. Streeter called attention to the large number of cases of cholera which occurred without preliminary symptoms, in which the collapse occurred with scarcely any vomiting or purging, and which he believed to be always fatal."

Dr. Baly thought that the diarrhœa should be considered in a threefold light. First, there was a diarrhœa in which there were one or two evacuations before the collapse. Second, there was serous diarrhœa, with rice-water evacuations and occasional vomiting before the collapse. In both these instances, the diarrhœa was uncontrollable. But there was another class of cases in which there was a diarrhœa continuing for a variable time, usually several days, before the cramps and vomiting occurred; and this he regarded as a curable affection. The comment to be made upon this is, that while Dr. McLaughlin discovers that, in 1849, *all* the cases of cholera were preceded by diarrhœa, Dr. Streeter found that the cholera of that season was remarkable on account of the large number of cases unannounced by the preliminary symptoms. The modification which follows this part of the quotation may be claimed by Dr. McLaughlin as a support of his assertion; but of what practical avail is a diarrhœa of one or two stools, which, in the language of Dr. Baly, is uncontrollable? Besides, there is such a thing as *cholera sicca*, a cholera in which there is nothing which can be called a diarrhœa. Without giving too much credence to the reports from India, that men have died of cholera in five minutes from the instant of the attack, without any evacuations of any kind, we cannot discredit such a statement as that of Dr. Gull, when he tells us that in his own practice, "On *post-mortem* examination, the large intestines contained healthy fæces; while in the upper two-thirds of the small intestines, the mucous membrane presented the usual changes induced by the cholera process, and the rice-water effusion was abundant." Literally, then, in a very few cases, the collapse is not preceded by diarrhœa, and practically in a considerably larger proportion, but still in a small minority of all the cases.

Dr. Vaché, in reporting forty-six cases treated in the Centre Street Hospital, after it was re-opened in 1854, says, that forty had the preliminary diarrhœa, and six had not. There are physicians who compliment me by their attendance here to-day, who can assure us, from their own experience, that cases do occur in which what are regarded as the symptoms of full cholera are not preceded by a diarrhœa that can be considered as an admonition. If you look over any of the reports of epidemics, whether the cases are given in detail or tabulated, you will not fail to find the appropriate entries, or the blanks which show that diarrhœa did not precede the graver symptoms of cholera, at least in a small minority of the cases.

Dr. McLaughlin is confident that cramps occur in every case of cholera, and he cites the authority of the physicians of the six London hospitals, and that of the thirty-six "Poplar Union" physicians, to justify the statement that they are characteristic and essential. Now, I think, if you will examine any series of reported cases, you will not fail to discover, every now and then, an instance of fatal cholera in which no cramps have occurred. In the twelve cases I have frequently referred to, twice there were none from the beginning to the end; and once they were so slight as not to attract much attention. I do not think cramps are essential to the phenomena of cholera; they are so much to be expected that their absence is pretty certain to be noted. —Dr. McLaughlin may urge that the fingers and toes, at least, are stiff and clumsy from spasmodic action, in the cases reported free from cramps; but even if this claim is allowed, its importance would be theoretical rather than practical.

Reports of Hospitals.

BELLEVUE HOSPITAL.

PROF. F. H. HAMILTON'S CLINICS.

I. Fracture of Clavicle—Ligamentous Union. II. Partial Anchylosis of Right Elbow. III. Colles' Fracture. IV. Apoplexy. V. Perforating Wound of Abdomen; Recovery. VII. Refracture of Patella; etc., etc.

Reported by John Winslow, M.D.

Monday, 8th January, 1866.

Many old cases are brought up to exhibit their progress; a few are here given:

I. Fracture of Clavicle: Ligamentous Union.—Subject, an old woman. Fracture of outer end of middle third, of three weeks' standing. The inner fragment overrides the outer, one-half inch, and the two are now firmly united by a very short ligament. "I anticipate that the connexion will ultimately become bony, since, in the case of the clavicle, delay in the ossific deposit is not infrequent, while permanent ligamentous union is very rare. With union by ligament, the strength of the arm is unimpaired, except for raising weights above the shoulder. This was proved in a case I have before reported; and, again, in a recent case seen by my son at Fort Schuyler, where the ligament was an inch in length."

II. Partial Anchylosis of Right Elbow, in a young man, consequent upon a fracture of the olecranon process. Forearm nearly extended, with motion through ten degrees. Complete extension is prevented by the olecranon's no longer fitting into its humeral fossa. This is irremediable, but of slight importance. "The imperfect flexion is apparently due to contraction of the triceps, which I shall now attempt to overcome, even at the risk of refracturing the olecranon; for the arm is at present useless, and if this process is fractured, it will again unite by ligament."

The patient is etherized, and the limb slowly, but forcibly and completely, flexed,—guarding against luxation of the radius. During the first half of this flexion, there is only a gradual yielding of the contracted tissues; but towards its close the jerking movement indicates rupture, probably of fibrinous adhesions. This flexed position is to be maintained by bandages for a few days, and then followed by systematic motion. This case illustrates the fact that in this fracture the great danger is from anchylosis, compared with which that of ligamentous union is insignificant. Early and frequent passive motion is, therefore, essential,—the olecranon being meanwhile properly supported.

III. Colles' Fracture, in an old woman; reduced two weeks since, and treated by a single straight splint, on the palmar aspect, extending from the elbow to the metacarpo-phalangeal articulation; this carefully padded, most thickly just above the point of fracture, and not at all immediately below; the roller applied most tightly over the lower fragment. In removing the dressings the hand is held prone, in which position the fragments of bone retain their place without support. No deformity is apparent; but we have incipient anchylosis, and passive motion must be practised as often as every second day. Reduction of this fracture is, in general, easily effected without extension, by pressing the lower fragment forwards with one thumb or both.

In Colles' fracture the radius is, in most cases, broken almost transversely, from one-half to three-fourths of an inch above its articular surface. The radial side of the lower fragment is rotated backwards and across the ulnar side, which remains fixed by ligaments. Overlapping is rare, occurring perhaps once in ten or twelve cases.

Barton's fracture consists in a chipping off of the posterior lip of the lower end of the radius. "We often see cases of this fracture reported in the journals, but we have been unable to find a specimen in an American museum; and, so far as we can learn, there is but one well marked specimen in the world,—most of the cases reported under this name being, in fact, examples of Colles' fracture. The possibility of the occurrence of simple *luxation* of the wrist was denied by Dupuytren. I have seen one case which I believed was a simple dislocation; but this accident is certainly too infrequent to render it probable that it should interfere with your diagnosis. After an injury at the wrist, the practical question will almost always be: 'Is it a Colles' fracture or a sprain?'"

IV. Apoplexy.—"The feeble old man, whom you saw in ward eight, with compound fracture of the right tibia and fibula, was attacked last night with apoplexy. It has resulted in hemiplegia of the left side. There was no shock, physical or mental, to occasion the attack, and the vessel must have been ruptured under the ordinary pressure of the blood. It is the popular notion that robust and plethoric persons are especially liable to apoplexy; but my own experience is, that it is chiefly the invalid student and the infirm old man who are its subjects. It is apt to occur under conditions similar to those causing scorbutic petechiæ. Clearly, it is rather to weakness of the vascular coats than to increased force of the circulation that the accident should commonly be attributed."

V. Perforating Wound of Abdomen: Complete Recovery.—Parotitis from Morphia.—James M——, æt. 16, admitted last October in a state of collapse from a pistol-shot wound perforating the abdomen. No fæcal matter was ever discharged by the wounds. In consequence of the large doses of morphia employed to subdue the resulting peritonitis, he was attacked by inflammation of the parotid glands. He has now completely recovered, and is about to be discharged. Dr. Hamilton had known one other case where parotitis was clearly traceable to the effect of morphia.

VI. Refracture of Patella.—James T——, æt. 38, butcher, fractured left patella transversely some four years ago. It united by a short ligament, which was subsequently ruptured by a fall. The fragments are now separated three inches and one-half; and in such a case we need not hope for a second union of any value. The upper fragment is fixed in its position so that it cannot be moved, and the quadriceps extensor is useless,—the patient walking with a leather splint placed behind the knee.

The greatest caution should be exercised to avoid imprudent use of the limb for a considerable period after this fracture. But anchylosis is a frequent sequela, and should be equally guarded against. "It is my practice to begin, after about three or four weeks, slight passive motion, while carefully holding the feebly-united fragments in place.

"The most interesting feature of this case is, that the accident was followed by suppuration in the knee-joint, and yet there is a complete recovery without anchylosis. Under such conditions we anticipate, usually, death, loss of the limb, or at best anchylosis. But this fellow is a fighting character, and he seems to possess great tenacity of life. He is a perfect Barnum's Museum, a complete pathological collection. He recounts his battles and his wounds numerically. In battle No. 10 he obtained a strabismus externus and displacement of the pupil. In battle No. 17 he received a smashing in of the nasal bones. In battle No. 19 he was honored with a broken skull; in No. 20, with a fracture of the fourth and fifth meta arpal bones; in, No. 25, with a fracture of the patella; and in No. 30, with a re-fracture of the ligament, &c., &c."

VII. Amputation of Finger.—"The finger amputated Dec. 18th, under the most unfavorable conditions, is, you observe, nearly healed, and the stump is well shaped. We did not get union by first intention, this seldom or never occurring where inflamed tissues are incised and brought together. The patient, you remember, crushed his right index finger, Nov. 16th, the injury being accompanied with severe laceration of the whole finger, and immediate loss of the last phalanx. Phlegmonous inflammation supervened, with suppuration and necrosis. Amputation was made, by lateral flaps, at the metacarpo-phalangeal articulation. The head of the metacarpal bone was not removed; as, in the patient's enfeebled condition, a section of the bone would have exposed him to the dangers of osteomyelitis, while only slight additional deformity is the result of leaving it. The flaps were brought together by a bandage; sutures do not hold well in inflamed and engorged tissues like these, nor would adhesive plasters keep their places so well as the cloth roller. In amputations of fingers, I often employ the roller as a substitute for sutures and adhesive strips.

"We left the articular surface of the metacarpal bone intact, and the healing has progressed as rapidly as if it had been carefully removed. Within twenty-four hours after the exposure of a synovial membrane, its smooth polished surface usually disappears; and, under the microscope, very fine granulations are seen springing up. In two, or at furthest three, days, it has lost entirely its synovial appearance. I do not state that this rule has no exceptions, especially in large joints like the knee; but even here the secretion of synovia rarely continues longer than a week or two.

"Had the first phalanx, in this case, been sound, I should have preserved it; my experience being, that, in most cases, after such amputations, the patients have recovered some power of flexing the stump. This may depend either upon adhesions to bone or integument contracted during cicatrization by the tendon of the flexor profundus, or upon a thin falciform process, which, as Velpeau has observed, is generally sent off by this tendon to be inserted into the sides of the first phalanx. I have been able to show you two examples, during the present term, in which this power of flexion was recovered."

VIII. Chronic Rheumatic Arthritis.—"You saw, in the female ward, two cases of this affection seated in the ankle-joint,—both of long standing, and, upon admission, attended by much swelling and pain. They have

greatly improved, and one of the patients is about leaving the hospital. Some topical applications have been made, but I attach little importance to them as compared with the enforced and long continued rest, in a warm bed, to which, almost exclusively, I credit the cure."

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

STATED MEETING, MARCH 21, 1866.

DR. ALFRED C. POST, Vice-President, in the Chair.

DISCUSSION ON CHOLERA.

MR. T. MCELROY, by courtesy of the Academy, exhibited the model of a very unique surgical table, and also an invalid bed, after which

DR. HERZOG continued the discussion by referring to an epidemiological map prepared by the War Department of Bavaria, and which he had brought with him for the inspection of the Fellows of the Academy. This had been very carefully prepared from the most authentic sources, since a commission representing nearly every branch of science had been appointed with ample powers to investigate the laws which governed the epidemic there of 1854. Bavaria, he would remark in passing, represents a population of five millions, confined to comparatively a small area, and at the time presented peculiar opportunities for the study of the various causes at work in the progress of this scourge. The artist in the map represents what, for convenience sake, we shall style local epidemics by red lines, sporadic by green, and mere cholerine by those of a bluish tint. By this device the eye is very readily addressed, and our facts very easily marshalled into line. The commission to which I have alluded embraced, among others equally celebrated, such names as Liebig and Pettenkofer. They performed their duty ably, zealously, and thoroughly. They observed that the epidemic attacked some localities and avoided others, in obedience to other laws than those which govern portable diseases; that certain persons or certain vessels were not responsible for the introduction of this destroying power; or, in brief, that human travel had very little if anything to do with the question. They found that the direction of the winds or of the water-courses was a matter of no importance. Why, then, they inquired, as they narrowed down the results of their observations, are these choleraic visitations confined to certain streets, sides of streets, and even certain houses? This led to the search after specific causes, and we have the summary of their conclusions that a dry, solid, rocky, compact soil is uniformly exempt from the infection; while a wet, oozy, soft soil especially invites the invasion. The water underneath the surface of the ground is continually seeking different levels, and in its recession leaves the débris of various offending substances, which ferment and decompose in obedience to well known laws. The only requisite for the spread of the disease in a locality permeated by these underground streams, is the contact of choleraic stools.

The power of the excrements in the causation of the malady was well exemplified in the case of the laundresses employed about cholera hospitals; they were peculiarly susceptible to attack, and the attack almost invariably terminated in death.

DR. HUTCHISON, for the sake of giving the discussion a practical turn, wished to hear the experience of his brethren in the matter of treatment. He had acted his part in two epidemics. The one of 1849 he saw in the Mississippi Valley, and that of 1854 in this vicinity; and he had come to the conclusion that the preferable plan was to disturb the patient with as few medicines as possible. He had adopted the practice of free vomiting by stimulating emetics, such as common salt and mustard. These agents, he found, controlled the vomiting attendant upon the disease, after the production of their immediate therapeutical effect, much more certainly than creasote, hydrocyanic acid, or any of the salts of opium. They seemed to thoroughly clear the stomach of all offending substances; he remembered a case where the ejection of a piece of lemon-peel, dislodged from this organ by a mustard emetic, gave almost immediate relief. The vomiting of the disease he would set down as rather of a regurgitative character, and as indicative of what nature was striving to accomplish. He also aimed to procure bilious stools by the exhibition of calomel in one-grain doses every hour; in fact, he looked upon nature as an excellent indicator of the plan to be pursued, and had early learned to regard free vomiting and purging as very hopeful signs. For the cramps, he knew of no better plan than the forcible and continuous extension of the muscles—say, for instance, that if the arm were implicated, he would subdue them by putting the extensors upon the stretch. He thought also that some benefit in these cases had been derived by the use of anæsthetics and hot-air baths. He rather favored the method of introducing saline solutions into the circulation, notwithstanding the want of satisfactory results; he had adopted the method in five cases, all of which terminated fatally; none of these, however, were fair tests. Indeed there were many niceties involved in the question of failure; the mode of operating, the quantity, quality, and relation to each other of the materials, the specific gravity and temperature of the solution, etc. The formula he had employed in his earlier cases was as follows: Alcohol ʒ i., chlor. sodium ʒ iii., and water 1 pint. One or two pints were injected into the median basilar vein.

He afterwards employed the solution recommended by Dr. Gull, which was composed as follows: Chlor. sodium, 40 parts, chlor. potassium, 6 parts, phos. sod. 3 parts, and carb. sod. 40 parts. 140 grains were dissolved in 40 ounces of water, and injected at the temperature of 100°, 115°.

The solutions employed are intended to represent the fluids discharged from the blood, minus the organic materials. He desired to see this method of treatment more thoroughly ventilated.

DR. HERZOG'S experience coincided with Dr. Hutchison's; he had known of no recovery where this plan had been adopted. In reply to the question regarding the conclusions of the Bavarian Commission in the matter of disinfecting the evacuations, he would state that chloride of lime was an unreliable agent, and that the most satisfactory results had been derived from the use of the sulphate of copper; an instance or two being quoted where the epidemic was arrested in the residence of the patients immediately after the occurrence of the first case. The sulphates of iron and zinc had also been tried, and were highly extolled.

One part of sulphurous acid and ten parts of water was likewise a good combination. In this the soiled clothing was purified, and by it also the evacuations deprived of their noxious properties.

DR. HARRIS had verified in his hospital experience the observation of Pettenkofer, that almost all the first cases were rapid in progress and uniformly fatal; that these conditions prevailed until, to use the language of Dr. Blair, "the complement of mortality had been attain-

ed, when the type became milder and more amenable to treatment of any kind." He entertained the opinion that the disease was in some way portable, since, notwithstanding the maintenance of a cordon almost military in character, to prevent the communication of patients in buildings isolated some one hundred or two hundred yards apart, and the exercise of the utmost care in the disposal of the choleraic stools, the epidemic had spread from building to building. Here there was certainly no such thing as personal contact.

Dr. Herzog was reminded also that, according to the statements of the Commission, a local epidemic spent its force in twenty-five days. By the term local he meant certain districts, streets, or neighborhoods; and not, of course, a large aggregation of dwellings like New York city, or even towns of smaller dimensions.

Dr. Hamilton favored, upon the whole, the expectant plan of treatment, and his experience, like that of many present, embraced the observations of two epidemics; these he saw in the city of Buffalo. He had no faith whatever in the beneficial results of morphine or opium in the stage of collapse. He had also exhibited large doses of quinine without any favorable effect; he could recall two cases of recovery after thorough emesis, and would adduce as examples of the success attendant upon the administration of calomel in full doses, the salvation of many patients by a German practitioner not over scientific, but possessed of a good stock of strong common sense.

He would lay much stress upon a change of location as an element of success; he attributed quite a number of recoveries in his experience to the early adoption of this method.

Dr. Stiles recited his experience while assistant physician to the Kings County Hospital. He had there observed that many patients had died almost upon the instant that the limb was tied, as a necessary preliminary to the operation for introducing the saline solution. The medical staff then adopted friction in the direction of the venous circulation, with, as they conceived, happier results. He would warn against the danger of heat, which increased with the rise of the temperature; he had been led to this conclusion by certain experiments upon the lower animals. He would show the futility of the ice-bag plan of treatment, by merely reminding his hearers that there was a continual stream of warm blood coursing in the neighborhood of the spine which required some time to be cooled; and cooling the spine was claimed to be effected by the advocates of the method.

Dr. Foster gave his experience in the epidemic of 1832, at which time he was a practitioner in Scoharie county. He and his colleague had employed with manifest advantage large doses of calomel, larger perhaps than necessary, in conjunction with injections of warm starch, retained through the medium of towels applied to the anal orifice.

He was led to adopt this latter procedure by observing that the rice-water stools were very low in temperature.

The meeting then adjourned.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Conversational Meeting, March 14, 1866.

Case of Brain Abscess.

Dr. Andrew Nebinger related the following interesting case. He had been recently called upon to visit a young man aged 19, of scrofulous temperament, who had an *Otorrhœa* from infancy, which produced considerable deafness. He first saw him about twelve days ago, and found him suffering from a violent headache, with some sickness at the stomach—the latter only manifesting itself, however, when something would be introduced into the organ. There was no constant nausea. The pulse was somewhat quick and rather small, but no actual febrile disturbance could be detected. Knowing of the discharge from his ears, Dr. Nebinger inquired as to whether the usual amount and character of the discharge had continued since the accession of the condition then present. The mother of the patient informed him that it had ceased. On examination, he found the external ear of the left side almost completely closed with a deposit very similar to that found in the ears in scarlatina, and giving off a very offensive odor. The stench of the discharge had been extremely offensive all through; so much so indeed, that the boy had been looked upon as a kind of pest at the schools which he had attended, and had often to be detained at home on this account.

Severe headache was the chief complaint at this time. Under the impression that the actual disease was confined to the organ of hearing, means were employed to reinduce the discharge; but the headache continued, every means of alleviation employed being unavailable. Through the whole time his mind was perfectly clear, and there was no disturbance of intellect; he answered all questions propounded with perfect accuracy; vision was undisturbed; the sense of smell was good, and taste accurate.

On Thursday last (8th inst), the Doctor saw him in the afternoon. He did not complain of being any worse, indeed he said he thought he felt a little easier than usual. About ten o'clock that night, Dr. Nebinger was sent for, the messenger stating to him that his patient was in a dying condition. On arriving at the house, he found a great change had ensued since evening—the patient no longer recognised him. It appeared that he had attempted to get off the bed on which he was lying, and in the effort to do so, fell, and was unable to rise, which was the apparent commencement of his absence of consciousness. He was unable to reply to any questions put to him; and when the bed-clothing was moved from him, he would be seized with a chill, which seemed to be rather a disturbance of the nervous system than really a rigor.

At three o'clock next morning he died.

Autopsy.—In the middle lobe of the left cerebral hemisphere, Dr. Nebinger discovered an abscess containing two ounces and a half of laudable pus. The petrous portion of the temporal bone was roughened. The condition giving rise to the abscess had set up at that point, and extended itself, involving a large portion of the middle lobe of the cerebral hemisphere of that side. It had ruptured and partially emptied itself into the left ventricle.

In the right ventricle of the right hemisphere, a quantity of fluid was found, completely filling the cavity.

Dr. Nebinger narrated this case on account of there being during life no such disturbance of intellect as would be naturally anticipated where there was such an extensive amount of disease, and the absence of such abnormal revelations as might be inferred would be present during the progress of such an abscess.

Legalized Dissection in Pennsylvania.—A bill "to promote medical science by furnishing subjects for dissection from the Alms-House," has been presented to the Pennsylvania Legislature for its adoption.

NEW YORK PATHOLOGICAL SOCIETY.

STATED MEETING, JAN. 10, 1866.

DR. GURDON BUCK, President, in the Chair.

(*Continued from page 22.*)

CANCEROUS DISEASE OF FEMUR.

DR. VOSS presented a second specimen, a malignant tumor of the thigh, which he removed from a young man nineteen years of age, who died last Sunday. He saw the patient for the first time on New Year's day. He was of slender build, of very rapid growth, and had enjoyed good health until four months ago, when he first began to complain of pain in the upper part of his thigh. This pain was severe enough to prevent him following his vocation for a period of six weeks previous to the time when he first placed himself under regular treatment. He was at first treated by the surgeon who saw him, for hip disease, and the elastic extension was employed. "I saw him first on the first of January, and satisfied myself very soon, without the use of chloroform, that the hip-joint was free. He was very much emaciated with a very high fever, and a small pulse of about 130 beats a minute. There was a slight œdema of the left lower extremity, with a marked fulness immediately below the left trochanter. I examined his spine and his abdomen, and could discover no disease in those localities. There was no difference between the gluteal regions. He could not stand upon the affected limb, but could move it slowly, which motion occasioned pain in his abdomen. On moving the limb I felt immediately below the trochanter a slight crackling sound; it was neither crepitation nor fluctuation, but resembled more nearly the sensation produced over the inflamed vagina of a tendon. After pressing the œdema away, I thought I could feel a place where it was softer, where I could make an easier impression upon the part by my finger; and in the absence of any decided limits to the swelling, indicating the existence of a tumor, I thought it might be caused by a deep-seated inflammation. I accordingly made an incision at this point, but nothing but blood escaped. On introducing my finger into the opening thus made, I encountered a soft mass of substance which felt like coagulated blood, with here and there some nodules; and finally without effort touched the bone, which was bare, and the surface of which easily scaled off by the scraping of my finger-nail. I had then no hesitation in declaring what the nature of the disease was, and at once closed the wound, applying over it a piece of lint soaked in the persulphate of iron, and left the man, telling his parents what the end must necessarily be. The patient died eight days after, the wound having apparently undergone no change whatever in its appearance.

The autopsical examination was, on account of attending circumstances, very incomplete, as I only succeeded after a great deal of trouble in securing the thigh bone, not being permitted to examine into the condition of the other organs. During life the bone remained unbroken, but I suppose the fracture here seen was occasioned by handling the corpse. The tumor seems situated on the inner and posterior side of the femur, and seems to have originated in the medullary canal. On microscopical examination, the diseased mass is found made up simply of a small amount of stroma, and a disproportionate amount of cells, some of which have two, three, four, or five nuclei. One part of the external aspect of the bony shell which surrounds the disease is perforated immediately below the trochanter, the edges of which opening are everted. The tumor was covered partly by the quadratus femoris and the gluteus maximus muscle. The disease is that which is known as fungus hematodes of the medullary canal. The results of the microscopical examination appear to correspond with the clinical history of the case, the large amount of cells accounting for the rapid growth of the tumor.

MALFORMATION OF THORACIC ORGANS.

DR. LEWIS SMITH exhibited a specimen of malformation of the thoracic organs taken from an infant in the Nursery and Child's Hospital, who died at the age of five hours. The mother was attended in her confinement by the house physician, and from him the history of the case was obtained. The woman stated that she was formerly married, and was the mother of two healthy children, one fourteen and the other sixteen years of age. Her husband died three or four years ago, and of course this last child of hers was illegitimate. She believed that the malformation was induced by grief. The infant at birth cried vigorously, but soon after became livid, and gradually sank and died.

On making the post-mortem examination, the abdominal viscera were found healthy. The lungs were in a state of atelectasis. The heart was about the normal size, but the right side was larger than usual; the left, smaller. On opening the pulmonary artery, its valves were found to be perfect, and were somewhat larger than was natural. The pulmonary artery was also somewhat enlarged; and on tracing it, I found that beyond the point where it divides into the right and left branch it continued as the aorta. The right auricle was enlarged, and the cavæ, as usual, entered it. The septum between the auricles, and also between the ventricles, was perfect; the valvular opening between the auricles being closed by a thick membrane. On the left side of the heart the ventricle was found in a rudimentary state, having only the capacity for a small bean, and was lined by a dense fibrous membrane. There were only two aortic valves, instead of three. The ductus arteriosus was absent, and the aorta was pervious, but very small. This latter vessel, as far as was possible, supplied the superior extremity and right side of the head. The pulmonary veins were found to enter the left auricle. This specimen of heart, then, was one of only two well formed cavities—the right auricle and ventricle—instead of four cavities; the left side of the heart being only in a rudimentary state. It is evident that the circulation must have been abnormal before as well as after birth.

In conclusion, he remarked that two specimens similar to the foregoing had been presented to the Society; one by Dr. Dalton in 1855, and one by Dr. Clark in 1856. The first case lived but twenty-four hours; the second, six days.

ST. VINCENT'S HOSPITAL.—According to the sixteenth Annual Report of this institution, which is under the charge of the Sisters of Charity, there has been a gradual increase in the number of patients yearly admitted. In 1850, there were but 308 treated, while during 1865, 900 were provided for, and of these 376 were cured, 283 improved, 51 were no better, 104 died, and 87 remained. Fifty-six of the deaths were from phthisis, for the treatment of which 199 had been admitted. The excess of the expenditures over the receipts, which were $23,065.49, amount to $2,574.83. The medical Board consists of the following gentlemen—Professor Wm. H. Van Buren, President, and Consulting Surgeon; James O'Rorke, M.D., Patrick J. Clarke, M.D., and Joseph A. Kerrigan, M.D., Visiting Physicians; and Julius S. Thebaud, M.D., J. W. S. Gouley, M.D. and Luther Voss, M.D., Visiting Surgeons; O. J. Ward, M.D., Resident Physician and Surgeon.

THE ISLAND HOSPITAL.

THE Commissioners of Public Charities and Correction have recently taken a very important step in making separate institutions of the Bellevue and Island Hospitals. The change in the management of the latter institution, which has been made by the appointment of a separate staff, is well calculated to be productive of much good to both hospitals. The attending staff of Bellevue will now be enabled to perform its onerous duties more satisfactorily, and the Island Hospital will be rescued from that neglect which, under the old system of management, it has so long suffered from.

Ever since its foundation, the Island Hospital has been most unfortunate in many respects, and not the least so in reference to the matter of medical attendance upon its wards. Having been considered a part of Bellevue, it has heretofore been compelled to rely wholly upon such occasional visitations from the staff of that hospital as the opportunity and time of the respective members of the same would allow. The distance from the city, the want of facilities for ready transportation, and the amount of time which such visitations as could be made required, naturally enough prevented many of the visiting staff from giving that attention to the care of patients which their voluntarily assumed duties required of them.

The consequence of all this was, that almost the entire charge of the sick had to be left to the internes. Although the members of the house staff made every effort to meet this extra demand upon their time and energies, they fell far short of the proper performance of the duties thus unwillingly thrust upon them. Competent for the performance of the ordinary duties of their position, they, despite their good intentions, necessarily lacked that amount of skill and judgment which is possessed by older and more experienced men.

The practice of confiding the care of cases to the house staff became after a while, and of necessity, so generally practised, that it was not unfrequently the case that a visit from the attending physician or surgeon would not be made for many days together. This dangerous habit which the visiting staff had grown into, although with no design to shirk the performance of a duty, soon began to tell seriously upon the interests of the institutions, and to exert a very demoralizing influence upon the younger men.

It soon became evident that either the visiting staff must be increased in numbers, and the respective terms of service shortened, or the majority of the patients be continually subjected to inattention. Finally, as the result of considerable discussion, the Commissioners concluded to adopt the expedient, not only of increasing the number of the attending staff, but also of forming two distinct hospitals.

We have no hesitation in saying that, by the wise course thus taken by the Commissioners, the Island Hospital, as a distinct institution, will be incalculably benefited. Not only can the patients be better cared for, but the immense amount of valuable material which has literally been allowed to run to waste, can now be made available for careful study and observation.

The new staff is composed of sixteen members, six of whom are not members of the original Bellevue staff. The view which has evidently been had in the appointment of these latter, seems to look towards the establishment, at no distant day, of separate wards for the treatment of special diseases. The names of BUMSTEAD, NOYES, LEWIS SMITH, and ECHEVERRIA, certainly give color to such a surmise. This fact, too, taken in connexion with a bill which is now before the Legislature asking for the establishment of a distinct department for the treatment of syphilitic disease, is at least a very significant one. Whether, after all, anything may really come of it, we are of course at present unable to say. The circumstances themselves are, however, worthy at least of mention.

In conclusion, we would respectfully draw the attention of the Commissioners and the Medical Board to the urgent necessity for increasing the number of members of the house staff on the Island. There has been too much expected of these gentlemen heretofore, and they should at least have the same chance as their confrères at Bellevue.

THE Metropolitan Board of Health, by its prompt and energetic action in all matters coming under its jurisdiction, has already succeeded in winning the confidence of the community as to its efficiency. Every one of its many departments is now in working trim, and everything moves on harmoniously towards the accomplishment of its purposes. The sanitary inspectors have had their respective districts assigned them, and are busily engaged in making their inspections, and reporting the results of their observations. The police squads are ever ready to render their aid on all occasions, and have by their seizure of vast quantities of diseased meat and the abatement of hundreds of nuisances, already given satisfactory evidence of their

fitness for the task assigned them. The streets are being cleaned; contractors are held to the strictest accountability; and the citizens of New York and vicinity are made to believe that they have a right to expect something more of the Commissioners than empty promises.

In announcing the close of the winter term of Lectures at our different medical schools, we are happy to state that the attendance of students has been unusually large. Not only have the colleges in this city had full classes, but other similar institutions throughout the country have been likewise favored. The accession to our ranks will, consequently, be very considerable. Although our profession may be in some respects justly considered a crowded one, we will have always room for working men. Let us hope that the majority of the freshly-graduated will belong to this class. A goodly number have certainly started well by entering the various hospitals as internes.

Reviews.

LECTURES ON EPILEPSY, PAIN, PARALYSIS, AND CERTAIN OTHER DISORDERS OF THE NERVOUS SYSTEM, by CHARLES BLAND RADCLIFFE, M.D., Fellow of the Royal College of Physicians of London; Physician to the Westminster Hospital, and to the National Hospital for the Paralysed and Epileptic, etc. Philadelphia: Lindsay & Blakiston, 1866. 12mo. pp. 280.

It requires no ordinary amount of talent for observation and research to work successfully in such a field as the author of this volume has chosen for himself; and we deem ourselves safe in saying, from the manner in which he has treated his subject, that he can justly lay claim to the possession of the necessary qualifications. As the result of labors which have been prosecuted with a praiseworthy endeavor for the past dozen years to elucidate some of the many abstruse points connected with one of the most important branches of study, he has been able to offer to the profession a mass of facts which are of the utmost importance to the general practitioner. A firm believer in the existence of animal electricity, he starts upon the foundations already laid by Matteucci and Du Bois-Reymond, and after the performance of a number of experiments, he builds up a seemingly substantial set of theories concerning muscular motion on the one hand, and nervous power on the other, and draws therefrom some very interesting and valuable deductions with reference to the treatment of epilepsy, pain, paralysis, etc. In reference to the phenomena of muscular motion and nervous force, he makes the following broad assertions, of which he attempts to prove the correctness beyond a doubt, by a very ingenious train of argument:—

"That there are unmistakable signs of natural electricity in living nerve and muscle during a state of rest. That the natural electricity which is present in living nerve and muscle during the state of rest, is in the statical, and not in the current condition. That living muscle, when left to itself, is kept in the state of relaxation by the statical action of its natural electricity. That an electrical discharge analogous to that of the torpedo, is developed in the neighborhood of the nerve or muscle during a state of action. That a nerve or muscle is for the moment deprived of its natural electricity whenever it is thrown into the state of action by the shock of a coil machine, or by any other artificial means. That the action of a motor nerve in producing muscular contraction is one which may deprive the muscle of its natural electricity; for it may be supposed that the muscular fibres lie near enough to the nerve fibres to be within the range of the electrical discharge (analogous to that of the torpedo), which is developed in the neighborhood of the nerve during the time of nervous action; and that the muscular fibres are deprived of their natural electricity by the shock of this discharge, in precisely the same way as that in which they are so deprived by the shock of the current of the coil machine. That muscle, deprived of its natural electricity, passes into the state of contraction, because muscle so deprived is left free to yield to the action of the attractive force which is inherent in the physical constitution of the muscular molecules."

He also maintains that ordinary muscular contraction is not continuous, for the reason that the electrical condition of the living tissue is such, that immediately after the contraction occasioned by the loss of electricity, a state of relaxation is restored by the recovery of electricity. When, however, the electrical condition is lost, a permanent and continued contraction takes place; a good example of which condition is afforded in rigor mortis. He does not believe that a vital property of irritability has to do with the action of a motor nerve, or that a vital property of irritability has anything to do in causing contraction of the muscle. Further on he assumes that there is no essential difference between the action which issues in sensation and the action which issues in muscular contractions.

Before proceeding to elaborate his particular views with reference to this point, we will allude to the existence of two different electrical conditions which he affirms are possessed respectively by the longitudinal and transverse surfaces of each muscle and nerve when in a state of rest. These two electrical states are of course antagonistic; the longitudinal surface of the fibres being electrified positively, and the transverse negatively. In a state of rest these two conditions balance each other. Thus much being stated, we are the better prepared to understand the following statements by the author:— "(1) That the 'impression' which issues in sensation, reverses the electrical relations of the exterior and interior of the nerve fibres in the parts acted upon; (2) that this reversal leads to a state of action in the sentient nerve; (3) that this state of action implies the development in and near the nerve of an electrical discharge analogous to that of the torpedo; and (4) that this electrical discharge gives rise to sensation, if certain ganglionic cells of the sensorium happen to be near enough to be exposed to the shock;" the only difference between the production of sensation and motion being in this, that in one instance the electrical discharge tells upon the sensorial ganglionic cells, and in the other upon the muscular fibres.

After going through with the physiological inquiries pertaining to the subject, he prepares the way for the consideration of several questions in pathology connected with convulsions, tremor, pain, and paralysis. By the careful examination into the condition of the functions of respiration, circulation, and innervation in each of these disorders, he proves each disease to be the result of a depressed, instead of exalted degree of vitality; this depression in the vitality serving to disturb the electrical relations between the exterior and interior of certain nerve fibres. The remarks upon the treatment of these different diseases are exceedingly valuable, and we regret that our space will not allow us to present them in detail. The general plan pursued by the author is the tonic and stimulating one, and among other remedies he favors the free use of fats, and the administration of bromide of potassium,

phosphorus, and occasionally of opium and alcoholic stimulants. The reason given for preferring above others the particular articles mentioned, are such as to convince every one of their soundness, whether he is willing to adopt the author's theories or not.

The volume is a handsome one, and has scattered throughout it several well executed engravings.

STIMULANTS AND NARCOTICS: their Mutual Relations; with Special Researches on the Action of Alcohol, Ether, and Chloroform on the Vital Organism. By FRANCIS E. ANSTIE, M.D., M.R.C.P., Assistant Physician to Westminster Hospital, Lecturer on Materia Medica and Therapeutics to the School, and formerly Lecturer on Toxicology. Philadelphia: Lindsay & Blakiston, 1865. 8vo. pp. 414.

OF late years there has been a great deal of looseness of expression in connexion with the effects which different medicines produce upon the organism, and the inevitable result of this has been to bring the science of therapeutics into great disrepute. Arbitrary classifications of the effects of drugs have been made; and partly for the sake of convenience of reference, and partly for the reason that few have had the time or patience to prove the fallacies upon which these bases of classification rest, they have been accepted and endorsed by medical men. The author of the volume before us chooses to travel out of this beaten track, and gives us, as the result of very many careful observations, a very instructive, interesting, and valuable treatise upon one of the most important departments of therapeutics —viz. on the relations between stimulants and narcotics. Stimulation, according to his view, not merely includes the impulse to act, but a supply of the materials which are necessary for action; that is to say, the physiological activity of a given organ is not only increased, but its tissue at the same time actually receives nourishment. In the latter sense, stimulants are understood as constituting, so to speak, actual food for the body which is in the condition to require them; and hence, arguing from such premises, he ranks nutritious food first under the head of true stimulants. He draws a very distinct line between the stimulation proper—which is induced by small doses of such remedies as opium, alcohol, and chloroform—and the depressing influences which attend the administration of large doses of these medicines. In small doses, these remedies—usually known under the name of narcotics—really possess the power of stimulation; and he proves, in a very logical way, that this property of stimulation is the one which apparently produces the narcotic effect, by the increased tone which it gives to the exhausted system. When, through misconception of the true indications of a given case, the remedies are pushed to narcotism, the effect contrary to that of stimulation is brought about; the system, so to speak, is overwhelmed by a poison, and instead of healthful sleep, a comatose condition is induced, the irritation or pain being only displaced by another pathological condition. The argument in favor of the position which he assumes is well and clearly presented, and deserves a degree of attention from the reader which is only commensurate with the amount of thought and careful study bestowed upon it by the author. His researches in reference to alcohol, chloroform, and ether, are especially valuable to the practitioner. The work is a very readable and interesting one; the numerous well recorded cases that are found scattered throughout its pages tend to fix in the mind of the reader very many important points, which might otherwise be lost sight of.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE, designed for the use of Practitioners and Students of Medicine, by AUSTIN FLINT, M.D., Prof. of the Principles and Practice of Medicine in the Bellevue Hospital Medical College, and in the Long Island College Hospital, Fellow of the New York Academy of Medicine, etc. Philadelphia: Henry C. Lea, 1866.

THE object of the author in writing such a work as that now before us, has been to present such a digest of the Principles and Practice of Medicine as should be serviceable alike to the student and the practitioner. In following out such a plan Dr. Flint has succeeded most admirably, and gives to his readers a work that is not only very readable, interesting, and concise, but in every respect calculated to meet the requirements of professional men of every class. The student has presented to him in the plainest possible manner the symptoms of disease, the principles which should guide him in its treatment, and the difficulties which have to be surmounted in order to arrive at a correct diagnosis. The practitioner, besides having such aids, has offered to him the conclusion which the experience of the professor has enabled him to arrive at in reference to the relative merits of different therapeutical agents, and different methods of treatment.

The work is divided into two principal parts. The first part is made up of ten chapters, and treats of general pathology, and embraces the consideration of anatomical changes in the solid and fluid parts of the body. Part II., which comprises fully nine-tenths of the whole volume, is divided into six sections, which are severally devoted to the diseases of the following systems:—the respiratory, the circulatory, the digestive, the nervous, the genito-urinary, and fevers and general diseases. Without wishing to detract anything from the merits of other parts of the work, we would specially commend to careful study that portion which treats of the diseases of the respiratory and circulatory systems.

This new work, as a whole, will add not a little to the well earned reputation of Prof. Flint as a medical writer and teacher. The number of years in which he has been engaged in the active duties of his profession, both in public and private life, have given him an amount of experience which has eminently fitted him for the production of a work which must necessarily extend over such a wide range of subjects. We cannot see how it can fail to meet with universal favor.

We are sorry to notice, however, the indifferent style in which the work is got up, the paper being thin and of bad quality, and the type old-fashioned and poor. This, considering the great reputation of the house from which the publication emanates, is not only surprising but inexplicable. It is to be hoped that when a new edition is called for, which we have good reason to suppose will be very soon, we shall see it in a more becoming dress.

THE PHYSIOLOGY OF MAN, designed to represent the existing state of Physiological Science, as applied to the Functions of the Human Body, by AUSTIN FLINT, Jr., M.D., Professor of Physiology and Microscopy in the Bellevue Hospital Medical College, N. Y., and in the Long Island College Hospital, Fellow of the New York Academy of Medicine, Microscopist to Bellevue Hospital.—*Introduction:* The Blood; Circulation; Respiration. New York; D. Appleton & Co., 443 and 445 Broadway. 1866.

THE volume before us is the first of four which are promised, the whole to make an elaborate treatise on "pure human physiology." The introduction is devoted to the consideration of physiological chemistry,

and though the subject is not exhaustively treated of, is sufficiently complete in the study of the relations of the different proximate principles to nutrition, to be interesting and instructive.

The first four chapters are given to the study of the blood, its physical, chemical, microscopical characters being fully dwelt upon, as well as the different methods of analysing this fluid. We pass over this part of the work without any intention to enter into a lengthy discussion concerning parts which have but little interest to any but the physiological chemist.

The fourth chapter commences the second division of the work, which especially commends itself to the careful perusal of all. All the important phenomena connected with this great function are elaborately treated of, and all the conclusions which are arrived at are thoroughly substantiated by numerous interesting observations and experiments. That which refers to the action of the heart is so interesting and instructive that we cannot resist the temptation of giving to our readers some of the many points which seem to be established by the author, not only as the results of experiments of others, but by not a few which have been carefully performed by himself. After establishing the fact that the point of the heart, during contraction, is lifted by virtue of the sudden distension of the great vessels at its base, and that the organ at the same time twists its point and becomes hard, he asserts that the ventricles, during contraction, instead of elongating really *shorten* themselves. The elongation, which is spoken of by many observers as taking place during the systole, he conclusively proves is only apparent, and that such an appearance is produced only when the heart is examined in situ, and when its apex is consequently protruded by the distension of the great vessels at the base of the organ. Two of the experiments performed in support of this view, we give in the author's own words:

"A large Newfoundland pup, about nine months old, was poisoned with woorari, artificial respiration was kept up, and the heart exposed. After showing the protrusion of the point and the apparent elongation while in the chest, the organ was rapidly removed, placed upon a table, and confined by two long needles passed through the base, pinning it to the wood. It contracted for one or two minutes, and at each systole the ventricles were manifestly shortened. The point was then placed against an upright, and it receded with each systole about an eighth of an inch." In another experiment, performed some time after, the heart of a medium-sized dog was examined, first in situ, "by pinning it with two needles to a thin board, passed under the organ. The presence of these needles did not seem to interfere with the heart's action, and at each ventricular systole the point evidently approached the base To render this absolutely certain a knife was fixed in the wood, at right angles to, and touching the point during the diastole, and a small silver tube was introduced through the walls into the left ventricle. At each contraction, a jet of blood spurted out through the tube, and the point of the heart receded from the knife about an eighth of an inch."

In accordance with the results obtained by Marey, the action of the heart is divided into ten equal parts, three distinct periods, which occur in the following order:—1. The auricular systole, which occupies two-tenths of the heart's action; 2. the ventricular systole, which occupies four-tenths; and 3, the diastole, which also occupies four-tenths.

In the description of the functions of the aortic and pulmonic valves, we find that the following important statement is made, with reference to a new office which the latter valve is supposed by the author to perform.

"The action of the semilunar valves can be seen by cutting away a portion of the ventricles in the heart of a large animal, securing the nozzle of a double syringe in the aorta and pulmonary artery, and forcing water into the vessels. In performing this experiment, it will be noticed that while the aortic semilunar valves oppose the passage of the liquid so effectually that the aorta may be ruptured before the valves will give way, a considerable degree of insufficiency exists under a high pressure, at the orifice of the pulmonary artery. There is at this orifice a safety valve function, as important as that ascribed by King to the tricuspid valve. It is evident that the slight insufficiency at the pulmonic orifice may be even more directly important in protecting the lungs than the insufficiency of the tricuspid valve. The difference in the sufficiency of the semilunar valves, on the two sides, is fully as marked as between the auriculo-ventricular valves, and it is surprising that, since the observations of King, this fact has not attracted the attention of physiologists."

The heart sounds next claim an extended examination, and without detailing the experiments which are related as bearing upon the various causes which combine to produce them, we will merely state the conclusions which are arrived at. They are, in brief, these: The first sound is made up of, first, a sudden closure of the auriculo-ventricular valves; second, the contraction of the muscular tissue of the organ; and third, the impulsion due to the shock of the organ against the walls of the thorax. The second sound is merely produced by the sudden closure of the aortic and pulmonary semilunar valves.

The rhythmical contractions of the heart are physiologically explained in this way:—The heart is endowed with an inherent property, called irritability, which is preserved by the blood in contact with the lining membrane, as well as by the blood going to the substance of the muscle, while the passage of the blood through the organ is the natural stimulus to such an irritation, "and may be said to be *the cause of its regular pulsations.*"

After some remarks upon the influence of the nervous system on the heart, he gives us a well digested summary of certain causes of arrest of the action of the heart, which we can only briefly refer to in passing. The first cause is that of hæmorrhage; the second, that of mechanical injury; the third, that of distension; and the fourth, that of powerful impressions upon the pneumogastric.

Following these two exceedingly interesting and instructive chapters on the physiology of the heart, the arterial, venous, and capillary systems are severally taken up and very elaborately and intelligently discussed.

The remaining portion of the work, on *Respiration*, although it does not come up to that standard of high excellence which we are disposed to claim for that part which we have just gone over, is sufficiently worked up to make it very practical to the practitioner and very attractive to the student.

In conclusion we would take occasion to say that the work, besides being a valuable addition to the literature of the subject, is well written, well illustrated, and elegantly printed.

Quarantine Matters.—A bill "ceding to the United States jurisdiction over West Bank and Old Orchard Shoal, in the Lower Bay of New York, for quarantine purposes," passed the Legislature on the 13th ult.

Progress of Medical Science.

Hydatid Cyst of Pelvis—Retention of Urine—Removal of three quarts of Hydatids.—Mr. Thomas Bryant, F.R.C.S., has recently detailed in the *Lancet*, a very interesting case of retention of the urine depending upon the development of a large hydatid cyst in the pelvis. The patient was 50 years of age, a single man of steady habits, who was first afflicted with retention of urine in 1851, the attack at the time lasting for a week. During all this period repeated attempts to pass a catheter failed, when finally the urine was naturally voided. He had an immunity from a second attack until seven years after, when the same difficulty in catheterization was experienced, and the same satisfactory result in time ensued. Many years elapsed without any recurrence of this trouble, and it was not until Nov. 1 that he was attacked a third time. With the exception of some months previous to this last attack, when he voided only small quantities at a time, he was able to pass the usual amount of urine in a good stream. For several years he suffered from obstinate constipation, requiring the frequent use of cathartic medicines. When Mr. Bryant saw him on Nov. 5, 1865, he had passed only a few drops of urine for five days, and he had also suffered from constipation for a long time.

On examining his abdomen, it was found very tense from the presence of a cystic tumor which evidently had its origin in the pelvis, and extended nearly to the scrobiculus cordis. This tumor was very hard, fluctuating, and smooth on its surface. "On the right side it projected oddly forward, and on the left it passed up higher in the abdomen than on the right." The external aspect of the tumor gave rise to the suspicion that it was something more than a distended bladder, and this was confirmed by the circumstances which attended the different attacks of retention. Examining the pelvis through the rectum, it was found completely blocked up by a hard swelling occupying seemingly its entire cavity, and so firm that no impression could be made upon it. An attempt was made to pass a catheter and failed, the end of the instrument turning towards the left side. This being the case, it was determined to puncture the bladder through the rectum, and this operation was performed on the following day. The man was placed in the position for lithotomy. "The puncture was then made with a trocar and canula through the rectum in the presumed direction of the bladder, but nothing came. A second puncture was then made backwards towards the sacrum, as it seemed probable that the tumor had pressed the bladder backwards, but with no better success; a little clear fluid was drawn off with fine membrane. A third puncture was then made forwards with a similar result; and under these circumstances it was at once determined to cut down on the pelvic tumor through the perinæum. In doing so, the incision was at first guided by the index-finger of the left hand, and, having opened this canal, incisions were made guided by the index-finger of the left hand backwards towards the tense tumor, which was felt deeply seated." The contents of the growth were then evacuated, when it was found to be hydatid. In order to allow a free passage of the matter contained in the cyst, the perinæum was laid open backwards into the rectum. A free incision was then made into the cyst itself, when about three quarts of hydatid cysts were evacuated. The cyst was then washed out. The bladder was found to occupy the left iliac fossa, and after another attempt at catheterization, it was finally crowded to some extent into the pelvic cavity, and then with some considerable difficulty punctured by the trocar and canula, upwards of a quart of dark-colored urine being drawn off. "An elastic catheter was passed through the canula into the bladder, and both were fastened in position. The patient went on very well for three days, when he began to fail, and died at the end of the seventh day. The only result of the autopsy that is referred to is the finding of two diseased kidneys.

"It is tolerably clear," says he, "that the hydatid cyst had pushed the bladder well up into the left iliac fossa, elevating the whole viscus and prostate from the pelvis, thus stretching the urethra and displacing it completely to the left side. It is also clear that for many years the bladder had never been, as a rule, well filled; and for many months it had never held more than an ounce of urine. Under such circumstances, it seems probable that in the expansion of the bladder so placed against the bone in the iliac fossa, the urethra would be bent sideways at an angle towards the centre, and thus a retention would be produced. The natural relief, also, seemed capable of a somewhat similar explanation; for let the distended bladder become still further distended, the pressure upon it from the cyst would be comparatively greater, and as a result the bladder would be pressed still further upwards, and the urethra, again made straight by stretching the natural channel, would thus be again reöpened and relief secured.

"Respecting the present seizure, it is to be noticed that it had been induced by the same cause that had brought on the two former—compulsory retention—and that the passage of a catheter into the bladder was likewise impossible. It was accompanied neither with any great constitutional disturbance nor with much local distress, although it was tolerably clear that both the retention of urine and constipation were produced by the same cause, mechanical obstruction. The peculiar aspect of the abdominal tumor, its prominent projection on one side, and its unequal enlargement, were points of striking interest, and appeared to indicate the presence of something more than an enlarged bladder; although a distended bladder is not always symmetrical, and the history of the case went to prove that there had been a gradual encroachment of a pelvic tumor upon the organ. This opinion was also strengthened by the statement of the patient, which was extracted from him during his treatment—that he had never passed more than two tablespoonfuls of urine at one time for a great many months, and often felt as though the lower part of the bowel was paralysed."

Coffee.—Baron Liebig's compound method for making coffee is thus given by the *Lancet*:—With three-fourths of the coffee to be employed, after being ground, the water is made to boil for ten or fifteen minutes. The one quarter of the coffee which has been kept back is then flung in, and the vessel immediately withdrawn from the fire, covered over, and allowed to stand for five or six minutes. In order that the powder on the surface may fall to the bottom, it is stirred round; the deposit takes place, and the coffee poured off is ready for use. In order to separate the dregs more completely, the coffee may be passed through a clean cloth; but generally this is not necessary, and often prejudicial to the pure flavor of the beverage.

The first boiling gives the strength, the second addition the flavor. The water does not dissolve of the aromatic substances more than the fourth part contained in the roasted coffee.

The Propagation of Cholera—Theory of Prof. Max Pettenkofer.—With regard to the question of contagi-

ousness, Pettenkofer believes that the disease is propagated by human intercourse, and never without this; not, however, by simple contact with the diseased or their excretions, according to the old theory of contagion, but by means of certain local accessory causes contained in the soil. Temperature, wind, moisture or dryness of the atmosphere, and elevation of ground, are none of them essential for the epidemic occurrence of cholera, although they may, under certain circumstances, exercise great influence on its course; the only indispensable conditions are—the human intercourse yielding the germ in the excretions of cholera patients, and the soil developing this germ into activity.

The qualities of the soil considered as necessary for the development of the cholera germ are: 1st, that it is porous—*i. e.* permeable to air and water; 2d, that water exists at a certain depth below the surface (ground water or subsoil water); and, 3d, that the soil is in some degree impregnated with the products of organic decomposition, especially those of excrementitious origin. Respecting the first condition, Pettenkofer and the members of the Bavarian Commission for the Investigation of Cholera in 1854, have found, without a single exception, that the soil in towns or villages which were epidemically affected with cholera was porous, while localities built on impermeable rock were either entirely spared, or at all events exhibited only isolated cases.—*Lancet.*

The Action of Medicinal Preparations on the Teeth.—John Smith, M.D., F.R.C.S., Surgeon Dentist to the Royal Infirmary, in an article upon this subject in the *Edinburgh Medical Journal*, Jan. 1866, concludes as the result of experiments performed by immersing teeth in different ferruginous compounds, that some of these, when directly applied, do exercise a powerful effect on the substance of the teeth. "And," he states, "the ratio of the effects obtained would seem to prove that of all the preparations employed in these experiments that of the tincture of muriate of iron acts most powerfully; the sulphate of iron next; and next to that again, although in comparison very immaterially, the vinum ferri; the other preparations of iron appearing to be next."

Death while under the Influence of Chloroform.—Another death while under the influence of chloroform has occurred, and is related in the *Edinburgh Medical Journal*, Jan. '66. The patient was a young lady, seventeen years of age, who had repeatedly taken chloroform before for painless tooth-extraction. On the present occasion she applied to Dr. Jas. D. Gillespie, Surgeon to the Royal Infirmary, Edinburgh (who reports the case), for the purpose of having another diseased tooth extracted. Thinking that the pain might be rheumatic in character she was advised to bear with it a little while longer; but there being no abatement in the symptom the day for the extraction was fixed. After urging his patient to submit to the operation without anæsthesia, and his persuasion being of no avail, chloroform was administered. Having ascertained that the patient's clothes were loosely fastened, the surgeon placed her in a recumbent position on a sofa, and sprinkled a small quantity of chloroform on a napkin, held a short distance from the face, and commenced its administration. "She had not," continues the narrator, "taken above a very few inhalations when she became violent, struggling, and screaming out very loudly, as if she felt the extraction of the tooth. Having got a very small further supply of chloroform on the napkin I was proceeding to administer it when I thought she was sufficiently unconscious, so I put it aside; and taking up the forceps found further operations impeded by the jaws being firmly clenched. I managed, however, to force them open, applied the forceps, and extracted the tooth. I then rose from the side of the sofa, and went to the table, which was scarcely a yard distant, to get a tumbler of water to make her wash out her mouth, when I was startled by one or two long gaping respirations, the peculiar character of which I cannot explain, but which I have only heard when a patient was dying. Alarmed, I dashed some cold water over her face, which was deadly pale; examined the pupils, found them greatly dilated; pulled out the tongue, which was not, however, retracted; felt for a pulse, but in vain, and then became convinced she was hopelessly dead." Efforts at resuscitation were continued for an hour and a half, but to no purpose. The amount of chloroform actually used was not more than twenty-five minims. At the autopsy "nothing whatever abnormal was found, save that the left ventricle of the heart was very firmly and unusually contracted, and that it, as well as the left auricle, was perfectly empty. The right side of the heart was not gorged with blood, and there was no clot in any of the cavities." Dr. Gillespie is satisfied that the cause of death was to be referred to the heart. "Were I to hazard an opinion," he continues, "I would say my own impression is, that the patient, who was of a very excitable temperament, and who had been for many days suffering much pain, and intensely anxious for the removal of her tooth, must have been seized with a peculiar variety of syncope, characterized by spasm of the left side of the heart; and the fact of her being under the influence of chloroform prevented a healthy action of the heart being re-established."

Iodide of Potassium.—M. Payen, at the Academy of Sciences, remarked that this important medicine is rarely found in a state of purity. It is usually alkaline, and nearly always contains an excess of iodine. He has observed that saturated solutions of iodide, and also of bromide of potassium, unlike the alkaline chlorides, act in the cold on starch granules, which, under the influence of the solutions, acquire twenty or thirty times their natural size, so that the liquid becomes a colorless transparent mass. The commercial iodide, he states, is easily purified by saturating the potash with hydriodic acid, and by separating the excess of iodine by sulphuretted hydrogen, boiling, rest, and filtration. A solution of the salt so purified, it is said, remains colorless in a stoppered bottle after exposure to both diffuse and direct sunlight. In a slightly alkaline solution of the iodide, carbonic acid sets some iodine at liberty; atmospheric air produces the same effect, no doubt, because of the carbonic acid which is present. With regard to the curious phenomena of the alternate coloration and decoloration of iodide of starch by heat and cooling, the author believes that he has demonstrated that the decoloration by heat is occasioned by the dispersion of the amylaceous particles, the color returning when the groups of particles contract on cooling. In conclusion, M. Payen dwelt on the necessity of using the pure iodide in medicine, and pointed out that the reaction on starch described above, suggested a new inquiry into the physiological effects of the salts.—(*British Med. Jour.*)

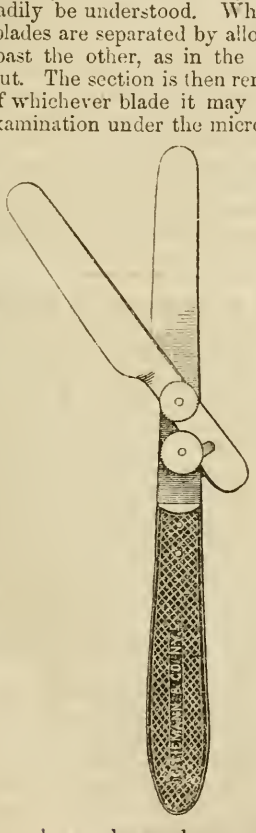
Morbid Anatomy of Pneumonia.—Dr. A. T. H. Waters, in a paper upon this subject, read before the Royal Medical and Chirurgical Society, stated his belief that engorgement was not the first morbid change which takes place in pneumonia, but that there was a prior stage characterized by a dryness of the pulmonary

membrane, and probably intense arterial injection. In proof of the probability of this condition, he referred to the existence of "a dry, harsh, loud, respiratory murmur preceding the crepitating râle."

Improvements in Instruments.

A NEW DOUBLE-BLADED KNIFE.

This instrument, devised by Messrs. Tiemann & Co., and represented below, is a modification of Valentin's knife for making sections for microscopical examinations. It consists, as will be seen, of two blades, only one of which is set in the handle; the other, or short blade, is kept attached to the first by means of two screws, the heads of which are shown. These screws are for the purpose of regulating the distance between the two blades. When the instrument is ready for use the longitudinal axes of the blades correspond, the slot in the small blade receiving the screw nearest the handle. The short blade is kept in position, while making a section, by slight pressure of the finger upon its short arm, as can readily be understood. When the section is made, the blades are separated by allowing the short one to slide past the other, as in the manner represented in the cut. The section is then removed from the inner surface of whichever blade it may adhere to, and is ready for examination under the microscope.



Parallel knives have always been much used by microscopists in making sections, but the great trouble has been that these instruments could not be used with ease or certainty. By the simple modification referred to, the principal objection which heretofore has always applied to Valentin's knife and its modifications, viz. the difficulty in removing easily the specimen from the blade, is now overcome. In this new instrument, by the sliding off of the blade, the specimen uninjured, is reached at once, and can be removed without trouble. The knife, after having its soiled portions cleansed (which can easily and quickly be done), is made ready again for use in an instant.

Correspondence.

THE COLLEGE COMMENCEMENTS—PROPOSED AMENDMENTS TO THE CONSTITUTION OF THE AMERICAN MEDICAL ASSOCIATION.

Philadelphia, March, 1866.

To the Editor of the Medical Record.

Sir:—The sessions of 1865–6 of the Medical Colleges of Philadelphia have been completed. On the 10th instant, the Commencement of the Jefferson Medical College was held, and the degree of M.D. conferred on one hundred and sixty-five graduates. Professor Rand delivered an excellent valedictory, short and to the point.

On the 14th instant, the Medical Department of the University of Pennsylvania held its Centennial Commencement at the Academy of Music, which was thronged with spectators from pit to dome, and out into the lobbies. Prof. Henry H. Smith delivered the Valedictory Address, and the degree of M.D. was conferred upon one hundred and sixty-two graduates.

Regular summer teaching will be inaugurated this year at the Colleges for the first time.

Through the munificence of Emeritus Professor Wood of the University, four auxiliary chairs have been endowed, from which instruction will be given during the summer on collateral branches of medicine which do not come under the regular curriculum of the winter schedule. These are Zoology and Comparative Anatomy by Harrison Allen, M.D.; Botany by H. C. Wood, jr., M.D.; Mineralogy and Geology by F. V. Hayden, M.D.; and Medical Jurisprudence by J. J. Reese, M.D. These lectures will be free to alumni and students of the University, a fee being demanded from others.

No wealthy admirer of the Jefferson Medical College having as yet lavished any thousands from which to pay for similar professorships, a labor of love is to be inaugurated this summer at this institution in order that its alumni, students, and matriculants, shall have the opportunity likewise of receiving daily clinical and didactic instruction in special departments of practical medicine, which can be but slightly touched upon during the regular winter course. Professors Gross, Biddle, Wallace, and Rand, have associated with themselves seven prominent clinical lecturers announced as attachés to the faculty. The branches to be taught will be most likely Ophthalmology, special departments of Physiology, Syphilology, Operative Surgery, Regional Anatomy, Diseases of the Nervous System, and similar branches, but the regular announcements are not yet out, and there may be some change in the programme. These lectures are to be free to the alumni and students of the Jefferson College, a fee to be exacted from others, but the Professors have no reserve fund from which to be remunerated as the more fortunate auxiliary faculty of the University. It is to be hoped that some liberal friend of the Jefferson College will ere long supply this deficiency.

The usual summer courses on Anatomy, Operative Surgery, Practical Obstetrics, and other special subjects, will soon commence, and with the usual facilities offered for summer tuition at the two great establishments, a large number of students will doubtless be induced to remain in the city.

At the meeting of the Philadelphia County Medical Society, held on the evening of the 14th instant, a discussion upon some proposed amendments to the Constitution of the American Medical Association was taken up, and the following may be in brief stated as the result.

To amend Article II, paragraph 4, by striking out from the first line the word "three" and inserting "five," so that the annual assessments of delegates and permanent members should be five dollars each. The portion of the amendment aiming to assess permanent members but three dollars was not favored.

They approved of the amendment to add to paragraph 14, Article II., after "unanimous vote," the following, "and shall continue such (*i.e.* permanent members) so long as they remain in good standing in the body from which they were sent as delegates."

The amendment to alter the third paragraph of the second section of the Constitution, so as to allow but one delegate to every twenty members of a local society instead of one to every ten as is now the case, was not endorsed.

They also supported an amendment to the twelfth paragraph of the second section, so that it shall read, "*The members by invitation,* shall consist of practitioners of medicine of reputable standing," "they shall receive their appointment by invitation of the meeting after an introduction from, and being vouched for by any of the members present, or any of the absent permanent members. They shall hold their connexion with the Association until the close of the annual session at which they are received, and shall be entitled to participate in all the affairs of the Association, but shall not have the right of voting."

The proposed amendment of the sixteenth paragraph of the second section was likewise favored, so that it shall read, "the permanent members shall at all times be entitled to attend the meetings and participate in the affairs of the Association, so long as they shall continue to conform to its regulations, but without the right of voting," and to repeal the remaining part of the paragraph.

The following additional paragraph was also approved of:—

"All Ex-Presidents and Ex-Vice-Presidents, and all permanent members of the Association, who have attended as delegates four annual meetings of the Association, shall possess all the powers and enjoy all the rights of elected delegates."

Lastly, a recommendation to strike out from paragraph fourteen, article eleven, page 341, *Transactions*, 1864, the following, "and of such other members as may receive the appointment by unanimous vote," was adopted.

The advantages and disadvantages of the proposed amendments were fully discussed in detail, and the foregoing result of the discussion is to be officially presented to their delegates as the unanimous instruction of the society with regard to the subject.

Yours truly,
C. J.

PRIZES OF AMERICAN MEDICAL ASSOCIATION.

PHILADELPHIA, March 16th, 1866.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In reply to numerous inquiries, permit me, through your columns, to state the conditions required by the Committee on Prize Essays, of all who desire to compete for the prizes offered by our Association.

"All communications, with motto attached, and name in sealed envelope, must be sent to the Chairman, Dr. Austin Flint, 257 Fourth Avenue, New York, *on or before* April 15th, 1866.

"If the authorship of an essay is declared to any of the Committee, said essay shall not be considered in competition for the prizes."

This Committee have power to "award *two prizes of one hundred dollars each,* to the best two volunteer communications reported on favorably by them, and directed by the Association to be published."

The volume of Transactions is now completed, and only awaits the insertion of the plates to be ready for distribution. In this connexion I would say that no one is entitled to it who has not paid the full subscription of five dollars. I am yours, &c.,

WM. B. ATKINSON,
Permanent Secretary American Med. Association.

CHOLERA IN 1832.

NEW YORK, March, 1866.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In the "Personal Reminiscences of the Life and Times of Gardiner Spring, Pastor of the Brick Presbyterian Church" in this city, a recent publication, are the following remarks.

"In the year 1831 the Asiatic Cholera desolated the city. It was a fearful season, during the months of July and August. It was was no unusual occurrence for twenty, thirty, fifty of our citizens to be swept off in a day. When the number of deaths daily increased to beyond one hundred, the alarm was terrific. Medical skill was altogether at fault, and medical men, not a few, and among them my own family physician, abandoned their posts and fled to the country."

The year mentioned in the above extract, page 212, is not correct. It should be 1832. Can any of the brethren, familiar with that epidemic, testify to what extent physicians "abandoned their posts and fled to the country?" E.

DR. O. D. POMEROY'S INHALER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In your issue of March 15th, you do not seem to have had a clear idea of the construction of the Inhaler labelled with my name. I will quote:—"The nozzle of the instrument is bulbous at its extremity, for the adaptation of elastic tubing, when it is found necessary to connect it with any other instrument, such, for instance, as a catheter. The other extremity of the instrument is tapering, for introduction into the nostrils." By this it would seem that there are two nozzles to the instrument; one bulbed, for the reception of an elastic tube, the other tapering, for introduction into the nostrils. The facts are these: the tapering end is for introduction into the nostril, and also admits of receiving upon its extremity an elastic tube, by which to connect it with a catheter.

You speak of the Buttles instrument being better suited for introduction into the mouth. This instrument was only intended to be applied to the nostrils.

Dr. Buttles himself has a glass inhaler, which has not this objection; the sponge being introduced at the base of the instrument which protrudes from the mouth, when adjusted for inhalation.

This instrument could not be so constructed, as the aperture for the insertion of the sponge must needs be too large to admit of an elastic tube of convenient size to be attached to it, and besides, whenever the sponge was adjusted, the tube must be removed.

You suggest the adaptability of instruments of this class, for the "treatment of all those catarrhal affections in which it might be necessary to bring medicated vapors in more perfect contact with those parts which might be beyond the reach of currents induced by ordinary inspiration."

In many cases of inflammation of the middle ear, we

have as a concomitant, chronic naso-pharyngeal catarrh, which must be attended to, or the ear difficulty progresses unfavorably. (It may indeed, as is often the case, have been caused in the first place by the catarrh.) In such cases, I think great benefit is derived from the injection of iodine vapor, by means of this apparatus into the nasal cavity, when it will come in contact with every part of the diseased surface. My experience with this mode of treatment is limited, but it has thus far seemed a valuable assistant to the treatment of this very annoying affection, especially as fluid injections are not, in many instances, well borne. The same treatment is applicable in ordinary nasal catarrh. By attaching to the inhaler an apparatus for volatilizing by the agency of heat, a great variety of therapeutic agents may be employed, either for treating diseases of the nasal passages or of the middle ear.

Very respectfully,
O. D. Pomeroy.

Obituary.

PROFESSOR SCHUH, OF VIENNA.

Dr. Frans Schuh, late Professor of Surgery in the University of Vienna, Austria, whose death we announced in our last number, was born in *Scheibbs*, in Austria, in 1805. After passing through the usual preliminary course, he began the study of medicine in Vienna, and received the degree of Doctor of Medicine and Surgery in 1831. After some time spent as an assistant to Baron Waltman in the practice of Operative Surgery, he was made in 1836 Professor of Surgery in Salzburg, and in 1837, one of the Surgeons to the General Hospital in Vienna, and in 1841 was made Professor of Surgery in Vienna, which position he continued to hold until his death. Professor Schuh was best known by his great work on the *Pathology and Therapeutics of the Pseudo-Plasma*, in which for the first time the investigations made by the microscope were made available for the practice of surgery. He was also the author of a work on Facial Neuralgia and the Resection of Nerves. His admirers claimed for him, that he was "a reformer in surgery in the noblest sense of the word, being to this science and art what *Skoda* is for the diseases of the chest, and Hebra for those of the skin."

The casual American visitor attending the clinic of Professor Schuh would hardly come to the same conclusion. His manner was rather commonplace, although his clinical lectures were marked by strong common sense, and his clear unembarrassing method of questioning the students in regard to the cases which were presented to him was something very pleasant to hear. He was a man of perhaps a little below the average size, and had a bright genial face.

Appointments.

Island Hospital.—The following gentlemen have been appointed as members of the new Medical Board:

Physicians—Drs. I. E. Taylor, Geo. T. Elliott, Austin Flint, Benj. W. McCready, Gonzales Echeverria, Wm. H. Thomson, Alfred L. Loomis, J. Lewis Smith.

Surgeons—Drs. Jas. R. Wood, Alex. B. Mott, Frank H. Hamilton, Lewis A. Sayre, Stephen Smith, F. J. Bumstead, Erskine Mason, H. D. Noyes.

Bellevue Hospital.—The following gentlemen have been appointed junior assistants to the house staff of Bellevue Hospital: Wm. R. Fisher, Drs. James B. Burnett, Henry D. Nicol, Charles Young, H. F. Walker, J. Calvin Mead, J. W. Howe, D. McLean Forman. The following are provisional appointees: Francis Dubois, Drs. Joseph O'Dwyer, Joseph S. Winston, P. Robertson Inches, Leroy M. Yale, R. L. Sykes, Dayton W. Searle.

Metropolitan Board of Health.—The following additional appointments have been made since our last issue:—Assistant Sanitary Superintendent, Dr. John E. Conklin, of Brooklyn; Deputy Register of Records, Dr. R. Cresson Stiles, of Brooklyn. Sanitary Inspectors: Drs. Alba Blaisdell, James L. Brown vice J. Lewis Smith declined, W. J. Deming, J. Haven Emerson, Guido Furman, E. H. Janes, Moreau Morris, and Robert Newman of N. Y.; Drs. J. M. Allin, G. W. Baker, James R. Bird, Frederic H. Colton, S. N. Fisk, and Fowler Prentis of Brooklyn, N. Y.

Faculty of the College of Physicians and Surgeons.—A very tasty and neat card, containing the vignettes of the professors of the College of Physicians and Surgeons, together with a view of the institution itself, has lately been published. The likenesses, which are all lifelike, are arranged in an oval, while a three-quarter view of the college occupies the centre. It has been published at the instance of the enterprising janitor, Mr. Denham, and is one of the handsomest pictures to its kind that we have seen.

Alumni Association of the College of Physicians and Surgeons, N. Y.—The Eighth Annual Meeting was held at the College building, corner Twenty-third street and Fourth avenue, on Friday evening, March 9th. The President, Dr. John G. Adams, in his inaugural address, gave some interesting points in the history of the institution, and paid a high compliment to those graduates who had in so large numbers sustained the reputation of their Alma Mater in the service of their country. The following gentlemen were elected officers for the ensuing year: President, Dr. Alfred C. Post; Vice-President, Dr. Gurdon Buck; Secretary, Dr. Ellsworth Eliot; Treasurer, Dr. Henry B. Sands. The Board of Councillors were, in the main, reëlected. The Standing Committee on Publication of the Triennial Catalogue was also reëlected, and consisted of the following: Drs. Gurdon Buck, Samuel St. John, Ellsworth Eliot, Henry B. Sands, and Dr. John Shrady, Jr. Dr. Samuel R. Percy was awarded the

prize offered by one of the Association for the best thesis on any medical subject. The title of the successful essay was: "What Effect has the Meat or Milk of Diseased Animals upon the Public Health?" Honorable mention was made of the following: "The Sanitary Condition of large Cities," and "Certain Diseases of Accommodation in the Visual Apparatus." A committee was appointed to confer with Dr. Percy regarding the publication of his paper, and the matter of prizes was put upon a permanent basis through the munificence of Dr. Delafield, who subscribed the full amount, $1500, as a fund to be invested, the interest of which should be devoted to the encouragement of medical writing on the part of the alumni. The Committee on Publication of the College Catalogue received the thanks of the Association for the elegant and satisfactory manner in which their duty had been performed. On motion of Dr. Gabriel Grant, it was substantially resolved that, by and with the consent of the Trustees, a tablet to the memory of all those who had fallen at the post of duty during the late war should be erected in the College at the expense of the Association. By a subsequent resolution, the officers of the association were constituted a committee, with power to confer with the Trustees and collect the necessary subscriptions. Dr. Ellsworth Eliot read a series of very interesting obituaries of members deceased since the last meeting, after which the meeting adjourned.

New York Pathological Society.—At the meeting held February 28th, the following gentlemen were elected members: Drs. A. Koehler, A. E. M. Purdy, and Wooster Beach, Jr. At the meeting held March 14, the following candidates to the American Medical association were elected: Drs. Finnell, A. E. M. Purdy, Rogers, Allin, Hamilton, Eliot, Peaslee, Bibbins, Bradley, Garrish, and Connolly.

New York County Medical Society.—At the next regular meeting, which will be held April 2d, Dr. William H. Thomson will read the concluding portion of his paper on "Chlorosis." Dr. Isaac E. Taylor will follow with a paper on "Recto-vaginal and Recto-labial Fistulæ."

The Obstetric Section of the N. Y. Academy of Medicine held its regular monthly meeting, March 19, at the house of the Chairman, Dr. Jos. Worster. The attendance was large, and the meeting was an interesting one. The discussion upon Dysmenorrhœa was continued, and remarks referring more particularly to the treatment of the affection were made by Drs. Church, Joel Foster, Van Kleek, Prince, Dewees, Peaslee, Hubbard, Bibbins, Garrish, Batchelder, and the Chairman. The remedies spoken of were naturally divided into those which were to be used during the paroxysm, and those which were to be employed in the interval. Of the former class, conium and guiacum, belladonna, camphor, opium, hyoscyamus, etc, hypodermic injections of morphine, and hip-baths, sinapisms to hips, etc., were more particularly recommended; while during the intervals the treatment was such as tended to meet the several indications, such as the use of iron, of Dewees' guiacum, leeches to the os, blisters to hypogastrium, and dilatation of os by means of bougie, sound, or sponge-tent. At the next meeting the "relation of cases" will occupy the members.

Harvard Medical School.—The graduating exercises of this school took place at the College, Grove st., Boston, on the 7th of March. Prof. Storer delivered the address. The graduating class numbered 70.

Eulogies on Dr. Mott.—The eloquent eulogy lately pronounced by Dr. G. S. Bedford upon Dr. Valentine Mott before the New York County Medical Society, as well as the one delivered by Prof. A. C. Post before the N. Y. Academy of Medicine, is shortly to be published in pamphlet-form.

The Army Medical Staff.—The bill introduced into the U. S. Senate by Senator Wilson for the reorganization of the army, has with some slight modifications passed. We extract that portion of it which refers to the Army Medical Staff:—Section 18 provides that the medical department of the army shall hereafter consist of one Surgeon-General, with rank, pay, and emoluments of a brigadier-general; one assistant Surgeon-General, with the rank, pay, and emoluments of a colonel of cavalry; seventy-five surgeons, with rank, pay, and emoluments of majors of cavalry; one hundred and fifty assistant surgeons, with the rank, pay, and emoluments of first lieutenants of cavalry, after three years' service, and with the rank, pay, and emoluments of first-lieutenants of cavalry for the first three years of service; and five medical storekeepers, with the same compensation as is now provided by law; and the vacancies hereby created in the grade of surgeon and assistant surgeon shall be filled by selection from among the staff and regimental surgeons and assistant surgeons of volunteers, who have served two years during the war; and assistant-surgeons who have served three years in the volunteer service, shall be eligible for promotion to the grade of captain. The Secretary of War is authorized to appoint from the enlisted men of the army, and to cause to be enlisted, as many competent hospital stewards as the service may require to be permanently attached to the Medical Department, under such regulations as the Secretary of War may prescribe. Section 19 reads thus:—"That upon the recommendation of the Surgeon-General the Secretary of War may detail a chief surgeon as chief medical purveyor, who, while performing such duty, shall be in charge of the principal purchasing and issuing depot of medical supplies, and shall have the rank, &c., of a colonel of cavalry; and not to exceed five medical officers, as assistant medical purveyors, who, while performing such duty in the different geographical departments, shall have the rank, pay, and emoluments of lieutenant-colonel of cavalry."

Trichiniasis.—At the suggestion of Prof. Rokitansky a committee consisting of Profs. Wedl, Röll, and Klob, has been appointed by the Imperial Society of Physicians in Vienna, to study and report upon Trichiniasis. Of the 350 persons affected during the late epidemic at Hedersleben, more than ninety have died. The village contained but 1800 inhabitants.—(*Boston Med. & Surg. Jour.*)

The Treatment for Sub-Acute Synovitis—Mr. W. Adams, of the Great Northern Hospital, reports that he has been employing for some time, with excellent results, the following plan of treatment: A large blister is applied to the skin, and over the swelling; the raw cuticle is removed by a scissors, and the raised surface is dressed with strong mercurial ointment. No constitutional disturbance is said to result from this treatment.

Errata.—Page 26 (Dr. Bumstead's article), 3d paragraph, instead of "Differences in characters, so-called" read "Differences in *chancres*, so-called." Page 29 (Dr. Clark's lecture), 1st column, line 27, read instead of "reached Astrachan in 1832," "reached Astrachan in 1823."

Original Communications.

A NEW
OPERATION FOR UMBILICAL HERNIA,

WITH REMARKS UPON EXPLORATORY INCISIONS OF THE ABDOMEN.

By HORATIO ROBINSON STORER, M.D.,

OF BOSTON, ASSISTANT IN OBSTETRICS AND MEDICAL JURISPRUDENCE IN HARVARD UNIVERSITY, SURGEON TO THE NEW ENGLAND HOSPITAL FOR WOMEN, AND PROFESSOR OF OBSTETRICS AND THE DISEASES OF WOMEN IN BERKSHIRE MEDICAL COLLEGE.

Umbilical Hernia has usually been considered one of the most unsatisfactory lesions to deal with in surgery. Its treatment, save when strangulated, has been generally confined to attempts at palliation, frequently fruitless; and a host of writers, as Skey, Cooper, Pancoast, Miller, Lawrence, Malgaigne, Erichsen, Nelaton, and Druitt, have failed to suggest any radical treatment whatever, merely loosening impacted intestinal protrusions in the complication referred to by crucial, T-shaped, or longitudinal incisions, or mentioning that where a ligature had sometimes been employed, in simple cases, the result had generally been fatal. To a large class of cases, those accompanied by ascitic effusion, scarcely any attention seems to have been given. In children, the edges of the ring, and at times small portions of the sac, have been removed by Barwell* with a successful result, and the same operation has been attempted in the adult.

The method pursued in the case now reported is, so far as I am aware, a novel one. I believe that it will be found worthy of being followed as a precedent in a large and varied class of diseases, and I therefore present it, with a statement of the several criticisms that have already been vouchsafed me, to the intelligent notice of the profession.

Mary Lynch, æt. 41, entered the Woman's Hospital of Boston on the third of June, 1865. She had long been suffering from hepatic disease. A patient of my father's some fifteen years since, my own knowledge of her ran back more than ten years, to 1855, at which time she had been under the care of Dr. Nathan Hayward and myself, at the Eustis St. Charitable Dispensary then existing in Roxbury. During this long period she had always been an invalid, with occasional attacks of jaundice and hepatic pain. She had been in most if not all of our hospitals, so patient and uncomplaining as to be a not unwelcome inmate, and her case must have been a familiar one to many medical men. By several of those who had had charge of her, she had been thought to have malignant disease, by others chronic inflammation; all, however, had concurred in pronouncing the liver the organ affected. She was now ascitic, and had already been once tapped at the City Hospital.

I admitted her to the Woman's Hospital, contrary to my usual custom in other than purely pelvic disease, because there had been some slight menstrual derangement, and I thought that to this, as indicating the approach of the climacteric, might be referred the change, ascitic effusion, that had occurred in the progress of her case.

From this time forward the ascitic symptoms became more and more marked. The woman's condition at admission was feeble, so that I did not anticipate she could be kept living more than a few weeks; no less than nine months, however, elapsed before her death. Towards the close of this period, the effusion of fluid was so rapid that it became necessary to tap her twice a week; the amount removed varying from two to three gallons, according as she was able to bear more or less upward pressure upon the diaphragm, and the dyspnœa that it produced.

The uterine symptoms, I have said, were slight. Vaginal examination showed only a little hypertrophy of the upper uterine walls. There were present from the commencement, one or two peculiarities recognised as such during abdominal examination, and satisfactorily accounted for at the autopsy. These are interesting in their connexion with differential diagnosis. There was lateral tympany both before and after each tapping, no matter what the position of the patient; an unusual condition in ascites. There was always an obstruction to the escape of serum when punctures were made at the flanks, and the obstacle could not be removed by passing a probe or sound, as can be done with partially floating intestine. There was often a dulness and induration extending down from the right hypochondrium into the iliac region, perceptible also after tapping and apparently continuous from the liver. By several gentlemen who had essayed palpation, it was pronounced as unequivocally the downward prolongation of an hypertrophied right lobe. That this was a mistake was ascertained at the first of the abdominal sections I am about to describe; the causes of the other peculiarities referred to were determined at the autopsy. After every tapping, the abdomen became flat, with the exception of the right side just alluded to, and the epigastrium, a little to the right of which there was at times a rounded tumor nearly of the size of the fist and very sensitive, which I proved long before her death to be the distended gall-bladder.

The patient had always expressed the deepest interest in her case. Many years back, though a Catholic, she had compelled me to promise her an autopsy, if she should die under my care. Soon after entering the hospital, she began to importune me to make an exploratory section, as she was convinced I should find her disease dependent upon some outgrowth capable of removal. To this I long demurred, but believing that exploratory incisions are comparatively safe, and that, if oftener made, they would frequently disclose curable disease previously doubtful or unsuspected, I at last consented, and on the 21st of November, 1865, subjected her to the first section, which was solely of an exploratory character.

The incision was made downwards, from just below the umbilicus, and of a length freely to admit the index and middle fingers. The abdominal wall was so anasarcous that drops of serum were discharged, before I opened any point whatever of the peritoneum. I carefully examined the organs of the pelvis, finding the ovaries normal, but the uterus slightly enlarged, the abdominal cavity free from outgrowth of any kind, the liver atrophied rather than hypertrophied, no prolongation whatever of either of its lobes, and the gall-bladder distended and tense.

The wound was closed by four metallic sutures, and they were protected from contact with the bed-clothes by a hooped frame. Upon the fourth day the sutures were untwisted, and upon the fifth they were withdrawn, union being complete and firm. Effected as this was under the most adverse circumstances, there being constant upward pressure from the ascitic fluid, the result was a very satisfactory one.

In a week or two the patient was as well as before the operation; nay, indeed, she seemed improved. The rapidity of ascitic secretion was not in the least affected either for better or worse; the disease had been steadily progressing in this respect, ever since she entered the

* *Lancet*, November, 1861, p. 471.

hospital. Some two months after the section, that is to say, at the opening of the present year, my attention was called to the condition of the umbilicus. This had been gradually becoming more and more patulous until it was, when distended, but little more than a thin membrane, partially, however, regaining its contractility whenever, by tapping, the pressure from within was withdrawn. There was evident danger of rupture; to prevent which, as it would have been very likely to cause the death of my patient, I was compelled to tap her oftener than I should otherwise have done.

Not merely did this distension of the umbilicus excite my fears; it became very painful to the patient. Attempts were of course made by pads and various forms of compress, by strips of adhesive plaster and the like, to keep the protrusion at the navel within due bounds, but these were alike unbearable and inefficient; the pressure even of the bed-clothes could not at times be borne, and the woman frequently begged me to attempt to mitigate her suffering.

Upon mature deliberation, satisfied that the risk of rupture was imminent, and that its occurrence, especially if at night, might kill so feeble a patient as this, by shock, for the laceration would have been more than likely to be extensive, and therefore to permit a sudden and profuse discharge, I determined to excise the umbilicus, by long incisions made through the whole thickness of the abdominal walls.

This operation, so far as I could then or since ascertain, had never been performed. I was aware that, whether successful or unsuccessful, it would occasion criticism, and that this, almost necessarily, might be severe, but in certain cases it becomes necessary to take the responsibility.

Upon the 4th of February, the patient having been tapped for the forty-fifth time, she was again etherized, and at 9 a.m. the operation commenced. I had determined to resort to a double incision, of so great a length that, upon bringing the edges of the wound together, there would be no gathering, puckering, or wrinkling, as must else have inevitably obtained. I therefore commenced my incisions at a point some three inches below the lower level of the umbilicus, and terminated them at a corresponding point some two and a half inches above the upper edge, their whole length being about seven and a half inches. They were therefore divergent for the first of the spaces named, nearly parallel for two inches, and again convergent till they met.*

I worked from below upwards, for convenience sake, since I had determined to prevent, if possible, any the slightest protrusion of intestine; and in this, by the simple expedient of inserting the sutures as fast as the incisions were made, I succeeded perfectly. These sutures were metallic, and twenty-one in number. From the moment they were twisted, not a drop of serum escaped through the wound; this could not have been so perfectly prevented, had the incision been shorter, as there would necessarily have been more or less gathering or plaiting of its edges.

The patient rallied perfectly after the operation, requiring but little in the way of direct stimulant, and, as in her former section, she was very shortly put upon small but frequently repeated doses of beef tea and boiled milk and flour. She did as well as could have been desired for twenty-four hours; at the end of this period, she received a sudden fright, whose effects were immediately perceptible upon her. She rapidly sank, and died at midnight of the 5th, of secondary shock, thirty-eight hours after the operation.

At the autopsy, on the following day, upon removal of the sutures, the wound was found completely united; throughout the greater part of its thickness for its whole extent, considerable traction upon the integument upon each side being unable to open the wound, and at no point of its surface could the smallest probe be passed.

The operation therefore, as an operation, was a success.

There was no sign whatever of recent peritonitic inflammation. The liver was not above the normal size, and presented evidence only of chronic inflammation. The gall-bladder was distended by large biliary calculi. The colon was adherent to the subjacent tissues throughout its whole extent, so that it could not be raised or separated from them; this state of things having evidently been of very long standing and perfectly explaining the abnormal diagnostic and other conditions already referred to. The uterus contained a small fibroid in its left upper wall anteriorly, the size perhaps of a chestnut. The ovaries and other appendages were healthy.

I reported the case at a meeting of the Suffolk District Society on the 24th of February, in the firm conviction that the operation, though a bold one, was authorized by the condition of the patient, and that it was the only one that indeed I should have been justified in performing. Some of my friends then present were, however, of so different an opinion, that I have thought the question of sufficient importance in its scientific aspects, and as establishing a precedent for the future treatment of similar cases, to submit it for decision to the profession at large.

In presenting the strictures of the gentlemen referred to, I have preferred not to rely upon my memory, but have submitted my notes of their remarks to their own personal revision.

"Prof. Calvin Ellis thought the operation liable to criticism. It had not been claimed that its performance was undertaken with the hope of curing the patient, nor that, with the single exception of guarding against rupture of the umbilicus, it could have materially prolonged her days, or have done away with the necessity of frequent tapping. Abdominal section was too grave an operation, was attended with too severe immediate risks, to be resorted to for the prevention of a possible accident, the removal of a danger that merely threatened. According to the reporter's own showing, there was reason to believe that there existed no abdominal or pelvic tumor capable of removal, and therefore the first section could hardly have been required.

"Prof. Richard M. Hodges could not see why removal of the umbilicus without opening the peritoneum would not have been an equally efficient operation, and far preferable because less dangerous. It was well known that such a method had been frequently employed in diseases of the umbilicus. As regards the question of securing immediate union of abdominal wounds, in cases where there had been previous distension, he thought if the patient lived long enough there could be seldom any difficulty in effecting it. This was particularly the case in sections for the removal of ovarian tumors, in which, from the subsequent laxity of the integuments, the edges of the wound were brought into very close apposition. He had frequently seen immediate union under such circumstances.

"In answer to the inquiry whether such union had been throughout the whole length of the wound, Dr. H. excepted, of course, the points where a pedicle or ligature had been brought through.

"In conversation after the meeting, Dr. Minot, who had presided, expressed the opinion that rather than

* The portion removed was subsequently exhibited to the Suffolk District Medical Society. After the operation, the umbilical sac of course underwent a certain measure of contraction, and this was still further increased by the alcohol in which it was immersed.

perform the operation, the umbilicus should have been allowed to rupture; that there would have been very little risk to the patient from this, even had it occurred at night. He would have punctured the distended umbilicus in preference to tapping elsewhere, and allowed the canula to remain in permanently. He did not consider that anything could justify the operation of excision of the umbilicus in such a case."

These several objections may be more conveniently considered, if presented in a tabular form.

It was asserted, by direct statement or by implication:

I. As regards the special case,

1. That no operative procedure whatever of a radical character was indicated.—*Dr. Ellis.*

2. That the removal of merely the umbilical integument would have been preferable.—*Dr. Hodges.*

3. That tapping the hernial sac and allowing the canula to remain permanently in situ would have been preferable.—*Dr. Minot.*

4. That even to allow rupture of the umbilicus would have been preferable.—*Dr. Minot.*

II. As regards my operation abstractly,

5. That nothing whatever can justify excision of the umbilicus in a similar case.—*Dr. Minot.*

III. As regards the general subject,

6. That abdominal sections are of themselves too dangerous to be employed for merely exploratory purposes.—*Dr. Ellis.*

7. That such sections should be undertaken only for the removal of tumors, pelvic or abdominal, previously diagnosticated.—*Dr. Ellis.*

8. That securing immediate union of the wound, in operative sections of the abdomen, is already the rule rather than the exception.—*Dr. Hodges.*

These several criticisms will require but a word of reply.

1. The operation was performed after long study of the case and careful comparison of possible gain and loss. It was neither experiment nor the result of hasty conclusion. The mere fact of excessive physical prostration or the existence of some chronic or incurable disease are not necessarily bars to the operation. They, of course, render it more perilous, and it is an advantage to have them absent. We must take our patients, however, as we find them; we are not to quietly fold our hands and do nothing, merely because their condition is not wholly satisfactory to us.

2. In ordinary umbilical hernia, uncomplicated with ascites, it is no doubt a much better procedure to make merely a superficial excision, leaving the peritoneum wholly intact, if it can be done, as is not, however, always the case. This method, had it been possible, would have been useless in the present instance. The peritoneum, having been so largely distended, would have been made to project inwards in plaits or folds. These would soon have been effaced by the rapid refilling of the abdominal cavity, and the want of correspondence with each other of the external and internal inclosing surfaces would have been likely to prevent adhesion of the edges of the wound, or, if effected, to break it down. I have no doubt of the excellence of this method in many instances of simple umbilical hernia. The present case, however, was a very different affair, and moreover the dissection of the superficial integument from the peritoneal membrane forming the hernial sac, could hardly have been performed, they were so intimately blended together. This membrane, it must be recollected, enters in such cases the opening of the umbilical ring. It lines the sac, and when this has been greatly distended, the procedure it is asserted I should have performed, may become for all really practical purposes, an impossibility.

Were it supposed that, granting the necessity of complete excision, the removal of the mere umbilical ring, a circular or small elliptical space, would have sufficed, and therefore from its more limited extent have been less dangerous, I should answer that it is particularly important to insure a perfect coaptation of the lips of the wound, and that when this is circular or even oval in form, it becomes a matter of extreme difficulty, if not impracticable, more especially when complicated with rapid ascitic effusion.

3. The plan of tapping the umbilicus was thought of, and more than once discussed. It was evident, however, that it was a procedure that would be not unattended with danger. So thin and membranous did the integument become during the bi-weekly intervals between tapping, that even a small opening would have been unlikely to heal. There had more than once been perceived an indolence in this respect of the lateral punctures, where the integuments were thick and therefore in a more favorable condition. Moreover, to have tapped at the umbilicus would have increased the risk of wounding the intestine, a knuckle of which was often plainly to be perceived within the sac. Attempts had been made to overcome these difficulties, and reduce the frequency of tapping, by allowing the canula to remain in position, in more than one region of the abdomen. In each instance, however, so much pain had been occasioned as to necessitate its early withdrawal. There is no reason to suppose that it would have been borne more easily at the umbilicus. The very sensitive condition of this, to which I have already referred, warrants the belief that the experiment would have occasioned unnecessary suffering.

In his work upon abdominal hernia, Sir Astley Cooper expressly warns against tapping at the umbilicus: "We often," he says, "see during ascites the umbilicus projecting, the skin thin, and a fluid evidently contained within it, and sometimes the water has been discharged by puncturing it with a lancet. Mr. Warner, formerly Surgeon of Guy's Hospital and author of several surgical tracts and cases, gives an account of a hernia being produced by puncturing the navel in dropsy, which is a valid objection against tapping the abdomen either at the navel or above it, both because it may lay the foundation of hernia, and because it is possible that a portion of intestine may adhere to the umbilicus, which would be wounded by the puncture."*

4. I have stated my belief that had the hernial sac been allowed to rupture, liable as it would have been to extensive laceration, the consequences would have probably been fatal to the patient. It is not so very many years since surgeons were in the habit of exerting pressure upon the abdominal walls by swathes, the many-tailed bandage, &c., &c;, during paracentesis, lest the discharge of even a trifling jet of serum might depress the vital powers by shock. The necessity of this was doubtless over-estimated. It were surely, however, the other extreme of practice to advise emptying the abdominal cavity by a wide opening, or to deny the existence of danger where such should accidentally have occurred.

5. The abstract statement that nothing can justify an operation in cases concerning whose special and individual features the objector has no personal knowledge, is at least sufficiently dogmatic. Such assertions are indeed unanswerable, but it is from the simple fact that from being in themselves unreasonable, they are incapable of being reasoned to.

* Anatomy and Surgical Treatment of Abdominal Hernia. Part II., p. 31.

6. The argument that exploratory sections of the abdomen are too dangerous to be justified, rests, like many of the aphorisms of surgery, upon a mere assumption; and this assumption an erroneous one. There is no hesitation felt by surgeons in opening the abdomen where they are sure of the diagnosis, and that an operation is required. It is found that there is little risk in opening the peritoneum for the relief of hernia, and the profession are gradually perceiving that the essential mortality of ovarian sections has been very much overestimated. I am accustomed to put little reliance upon statistical evidence, gathered as this necessarily is from sources the most diverse, as regards skill, experience, and credibility, and based upon cases the most various even in their points of similarity, but even the testimony of statistics seems concurrent towards decided tolerance of incised wounds by the peritoneum.

If we but change the field of inquiry and examine into the comparative justifiability of many of the operations of general surgery, even for exploratory purposes alone, I think I am safe in saying that my own operation would suffer nothing by the comparison. There are indeed some exploratory sections that have been made, and I need not go far for instances in point, that will hardly bear too critical discussion. A single reference will make this sufficiently evident.

On the 25th of June, 1858, an examination, to which the term vivisection was at the time applied, was made of a man in the Dead House attached to the Jail in Boston. The examination was conducted by the gentleman to whose criticism upon my own operation I am now replying. Previous to making any incision, it was noticed that "a slight but regular pulsatory movement was observed in the right subclavian vein. Upon applying the ear to the chest, this was ascertained to proceed from the heart itself, which gave a distinct and regular single beat, with a slight impulse, eighty times in a minute. The chest was then opened, and the heart exposed, without in any way arresting the pulsatory movements. The right auricle was in full and regular motion, contracting and dilating with beautiful distinctness and energy."* It is not my intention to refer to any of the medico-legal aspects of this case, though in view of the laws defining criminal responsibility, it will hardly establish a precedent that can safely be followed—nor will I dwell upon the fact that the man thus incised, and incised to death, for exploratory purposes, was a criminal whose end the judicial officers, who alone are justified in committing homicide for legal ends, had failed to accomplish. I need merely say that this antemortem autopsy showed most conclusively that all the vital organs of the body had escaped serious injury during the fall from the scaffold, "a small space under the left ear having escaped active compression, so that some circulation might have continued through the carotid and jugular of that side," and that, as was acknowledged by the reporter of the examination, "resuscitation might possibly have been accomplished within half an hour after he fell;" and if at that time, probably also an hour later, at the time of the section. I allude to this case with hesitation, for it reopens a most delicate though important question in medical jurisprudence, that might else remain at rest; but in relieving ourselves from the imputation of having been hasty or injudicious in our conduct, we cannot but recognise the pertinency of collateral illustration.

7. It is impossible, as yet, to be always sure, or ever positively sure, of an abdominal diagnosis. Upon this point I have offered some remarks in a late paper upon extirpation of the uterus by abdominal section, to which, as the subject is a most important one, I would here refer; at this moment reproducing but a single sentence to evidence my own opinion: "With regard generally to a more frequent resort to exploratory incisions than now obtains, I cannot express myself too favorably, and I believe that upon this point I represent the opinion of the best ovariotomists. There are some pressing cases, where it is absolutely impossible to be positively certain as to the existence of a tumor, let alone its differential diagnosis, even if anæsthesia has been employed. The fact that, upon incision, no tumor has been found in some such cases, has been made altogether too much of as an argument against section. As well might it be said that the cavity of the uterus is never to be explored by sponge tents, because in many cases of uterine hæmorrhage where they have been employed, only negative evidence has been attained."*

There are many, I am well aware, who are of decidedly a different opinion. In the discussion, however, of operations, as of medicinal procedures, it is often the case that those criticising the most severely are from among physicians with little practical and experimental knowledge of the matter in question. I do not apply this remark to the gentlemen to whose strictures upon excision of the umbilicus I have called attention, for their general good judgment, skill, and experience are well known; but it has been the case with the verbal ordeals through which have passed the uterine sound, the stem pessary, chloroform in child-bed, and a host of the other valuable appliances of my own department of the profession, unscathed.

That I have transferred the discussion from the field in which it occurred, I may remark, in passing, has been from no discourteous feeling to the other parties engaged, but for three good reasons, viz. that the question, having become a public one, belongs to the profession at large; that such, the only jury by which we stand or fall, is best reached through a journal of more than local circulation; and that for reasons stated on page 234 of the 16th volume of the American Medical Association Transactions, I could pursue no other course.

8. And finally: To the last of the points made, I cannot, for lack of time, do more at the present moment than refer. The allowance made by my friend, at the time my case came under fire, that by the general union of abdominal wounds by the first intention, he intended only such portions of them as did not include the parts where a pedicle or ligatures had been brought through, grants very material ground for which I have elsewhere been contending, and which has as yet been unaccepted by many surgeons. As one great step towards controlling even the present mortality of abdominal sections, operators must recognise the fact that in special sources of irritation that can be safely avoided, lie many of the dangers which still wreck their patients and discourage themselves.

In the hope that in excision of the umbilicus by deep incisions, and in the adaptation of a similar method of procedure to other forms of else incurable rupture, surgeons may find the means of more satisfactorily treating abdominal hernia, this paper is submitted for their judgment.

Hotel Pelham, Boston, 4th April, 1866.

DISCOVERY OF TRICHINA.—It is claimed by English physicians that to Mr. Paget belongs the credit of having first drawn the attention of the profession to the existence of this now celebrated flesh-worm.

THE ELIMINATION THEORY OF PNEUMONIA.

BEING AN ABSTRACT OF A PAPER READ AT THE NEW YORK ACADEMY OF MEDICINE.

By W. H. THOMSON, M D.,
OF NEW YORK.

In an interesting communication on the Pathology of Pneumonia, read at a recent meeting of the Academy by Dr. W. H. Draper, we understood the writer to advocate the theory that pneumonia is the result of the presence in the blood of a poison which Nature seeks to get rid of through elimination effected by means of the inflammatory exudation which fills the air-cells.

This view of pneumonia involves the acceptance of several theories, which, if accepted, cannot fail of wide application; for if they are true principles, it is hard to see why they belong only to the lungs, or that, having by them explained pneumonia, we should deny their operation in the other exudative inflammations which we find localized in certain organs or parts of the body. Pneumonia, as the chief local inflammation of pathology, may be fairly termed the great type of such affections. Whatever its etiology, or whatever its special features, arising from the peculiar tissue which it affects, it is still a true acute inflammation; so that the physician who thoroughly understands this disease, must equally understand the principles of inflammatory diseases in general. It was the common recognition of this fact in the profession which gave its importance to the discussion of its treatment which has been so prevalent of late years. Accordingly, when the view of its pathology advocated by Dr. Draper is advanced, we think we do not misrepresent it when we state it as a general proposition thus: Given an idiopathic, inflammatory exudation from the blood-vessels into the proper tissue of a part, Nature, in such case, has found a poison in the blood whose presence would be more perilous elsewhere; and therefore she institutes the process of inflammation in this tissue for the purpose of eliminating it from the blood and depositing it there, the whole forming an illustration of Nature's conservative powers. The exudation being an elimination, it would be an error to arrest it; for the more completely Nature eliminates, the better, and we should aim to assist her to go through the steps of her conservative process with as little hindrance as possible.

Were we convinced of the truth of this theory, we think it would be inevitable that thereafter the commonest ideas in our minds at the bedside would be two—poison as to etiology, and elimination as regards treatment. But preliminary to the adoption of any of these conclusions, it is necessary to have a clear knowledge of elimination itself; and if it appears, on examination, that the whole theory of elimination in disease as at present generally held, is in a great degree conjectural, even when applied to the action of the glands, whose function is eliminative in health, it seems sheer speculation to deduce from the presence of a pneumonic exudation: 1st, an eliminative act; 2d, therefore a proper poison to be eliminated; and then based on this, 3d, that if the eliminative glands cannot remove an injurious substance, Nature sets to inflaming some organ whose tissue will, when inflamed, best eliminate it.

I. The general theory of elimination, it is justly argued, appears probable from its analogies to a real and important function of life. The blood is constantly freed of certain ingredients which, were they not at once eliminated by the emunctory glands, would act as poisons and produce disease. It is not difficult, therefore, to suppose that if a materies morbi of any kind is causing disease in the system, Nature has the same power to get rid of it, and in the same way that she gets rid of the ordinary poisons. It does not, therefore, seem to be an unreasonable inference that the converse of this is equally true—namely, that when we have an apparently idiopathic disease, it is caused by a poison which Nature is striving to eliminate. This conception of elimination in disease, derived from elimination in health, is one of the most prevalent ideas in modern pathology; and it is as customary to recognise eliminative processes in pathological symptoms or states, as it was in the sixteenth century to perceive in the same conditions the working of animal spirits and humors. The study of this theory, therefore, cannot lack either in interest or importance, for besides other applications, we find it made to explain even the deep problem of hereditary structural diseases, the elements of which existed in the microscopic primordial cell, equally with that something which determined the shape of the future nose or mouth. Thus Simon speaks of cancer as "an eliminative act of Nature," and several writers assert the same of tubercular deposits. The most marked nervous diseases also find their places within the extensive territory of this theory; for Dr. Todd discerns the cause of epilepsy itself in a disordered venal elimination.

But it seems calculated to awaken suspicion to find that the main support of this great theory is upon analogy. Nothing can be *proved* by analogies, however indefinitely they may be multiplied; and meantime it is instructive to note how few well ascertained facts can be pressed into its service. It is only in one or two forms of chronic mineral poisoning, as the elimination of lead by iodide of potassium, that we are able to remove a poison by a measure of our own. On the other hand, and in striking contrast with these rare instances, we often find the process of elimination fail signally in practice both when it is most pressingly needed, and when, according to theory, it should best show its powers; so that experience teaches us to expect aid from quite other vital processes of the system. Thus, instead of reasoning about a supposed toxic agent settling in the lungs, but which has never yet been found, let us begin with an instance in which we know that a true and palpable poison, bought by measure, has just entered the circulation. Now in practice we rarely attempt to free the blood of such a poison, for the good reason that we have no means of doing so; but when once assured that it has entered the blood and is beyond the reach of emetics, our whole efforts are directed to the *nervous*, rather than to the glandular system—brandy and ammonia for a snake-bite; coffee, belladonna, and perhaps whipping, for opium. It may be replied that these measures have for their intention simply to support the nervous system until the eliminating glands have removed the poison; but to this it can be answered that the secretions remove too small a proportion of the poison, and too slowly also, to ascribe the recovery to elimination; while many of them become innoxious by being decomposed in the circulating fluid, and are therefore never eliminated in the secretions. That the salvation from the poison is due to living resistance and not to elimination, is shown, we think, by such questions as these: Is it owing to the great activity of the eliminating glands, or is it from the peculiar state of the nervous system, that some patients can bear enormous doses of opium while suffering from intense pain? Does cancer uteri, for instance, so promote elimination that no more effect was produced in some recorded cases by a pint of laudanum, than is ordinarily produced by twenty-five drops?

But these considerations press upon us still more closely when we note that we almost never think of resorting to elimination in the treatment of what are acknowledged as *atmospheric* poisons. Thus in a case of ague, we will neither sweat nor purge. We seek for aid, instead, from the most powerful nervine tonics we can find, such as quinine, arsenic, or the vegetable bitters, etc. Experience does not leave us to guess that, against real animal or malarial poisons, a vigorous vitality to resist their influence is of much more importance than the most perfect elimination by the glands—for, eliminate the poison *they* will not; every purgative, diuretic, and diaphoretic, failing equally to counteract a malaria, or cure a hospital gangrene. On the contrary, these agents are positively mischievous; for we can secure their action only at the expense of that life-power which is, after all, our main-stay against death in any form.

Let us also glance briefly at the meaning of the treatment by which we now try to counteract a great animal poison—that of syphilis. Formerly it was thought that mercury was beneficial, from its eliminative properties; so that Boerhaave advised the practitioner to obtain three or four pounds of saliva a day from his patient. This was certainly giving elimination a fair chance; but we suspect that the doctor who, in our day, would attempt this, instead of eliminating syphilis, would introduce into the case a no less curse in the shape of a lawyer! Our efforts, rather, under an improved pathology, are to prevent the mercurial from going out either by the bowel or by the mouth, hoping thereby to produce the same effect on this disease that small doses of arsenic produce in a case of lepra; an effect whose mode is equally unknown to us in either case, and which we do not term eliminative, but alterative. Meantime, instead of any evacuating or depleting agent, we seek to tone up the system by every means in our power. The conception of the syphilitic poison which the theory of elimination requires, is that of a definite ingredient in the circulation which causes one of its characteristic lesions here, and another there; and that the patient's recovery is owing to the removal of the last appreciable particle of this material from the blood. But we often find the disease reappearing upon some breakdown of health, years after the poison was thought to have been eliminated. Was this because the poison went on year by year, being secretly and constantly reproduced, and as constantly eliminated, until, the glands failing, syphilis again poisoned the system; or was it because this agent develops into an evil impress on the essence itself of physical life, to be felt to the third and fourth generation, but which remains concealed, while a strong vitality withstands the old infection, until, when a weakening influence prevents longer resistance, the working of the curse once more appears? For how as to hereditary infection? Is the syphilis in the aborted fœtus, or which speaks for itself in the growth of a miserable child, and which, in both cases, came from the father at the moment of conception,—does such syphilis show that, from deficient elimination on the part of the parent's intestines, or liver, or saliva, or skin, an atom of this poison pervaded the primitive vesicle?

We do not wish to be understood as denying to the function of the eliminative glands an important share in the recovery from disease. On the contrary, it is most desirable to secure them from interruption in their action while the system is laboring under abnormal and adverse conditions. What we consider to be an erroneous deduction is, that we can by them eliminate either the diseases themselves, or their proximate causes. Their action we conceive to be, in the majority of cases, simply the same as in health—namely, to remove the waste of the tissues, and in this office they are often as much disturbed or impeded by the disease, as is the case with any other function of the body. A patient with pneumonia cannot think, digest, or walk as usual, but neither can he eliminate as usual by his lungs, skin, intestines, or kidneys. Meantime, increased heat and other symptoms show that more tissue is being consumed, so that the waste products are accumulating more rapidly than usual. With more waste and less removal, it is easy to see that we have a serious complication apart from the original disease; and the benefit, therefore, from eliminative medicines is not because they eliminate the special disease, but from their bringing up the glands to their necessary duty. Accordingly, what we do find in the excretions in disease, is just of the same nature as at other times. We find no new specific addition from scarlatina, for instance, or from rheumatism. But, according to the elimination theory, the materies morbi itself is excreted; for, were it not carried out as urea, for example, but decomposed in the blood, then it cannot be said to be eliminated. Now, in the case of the urine, we have an important excretion, coming without foreign admixture, direct from the circulation; an excretion easily examined, and to whose examination much careful chemistry has been directed. What has been the result as to the diagnosis of disease through this great channel of elimination? Will any one, from examining a particular turbid specimen loaded with urates, tell us whether it come from a convalescent from small-pox, or typhus, or pneumonia, or from over-eating? In either case all that is, and we believe all that can be found, is a larger proportion of solids derived from an increased waste of tissue; and therefore to propose to cut short a disease by trying to eliminate it by the kidneys, is like attempting to put out a fire by diligently removing the ashes.

We now come, in conclusion, to the alleged eliminative function of inflammatory exudations. As in the case of gland elimination, this belief in the beneficent character of a suppurative inflammation is both ancient and popular. This very day we have had an old English lady object to our meddling with a whitlow, lest the naughtiness in the blood, as she expressed it, would break out in a worse place. We remember that when, many years ago, we were tormented, we were consoled on similar authority that boils were healthy; and it is well known how at water-cures the patients congratulate themselves on the first promise of a good crop of Job's sores. But we must now beg to differ with this pathology, and to suspect that, as in the case of the patriarch, they come from a bad quarter, and have no good intention about them; so that the sooner we stop them, the better. We can certainly, in practice, arrest their development, not only without a sign of internal mischief, but with positive advantage to the patient; while, according to the theory, we should recognise even in an extensive carbuncle, a preferable condition to what would have otherwise happened. This belief in the curative and depurative character of these superficial inflammations, is, we conceive, now the exclusive property of the hydropathists, and has been abandoned by all pathologists. It is, we confess, therefore not without misgiving that we find the same theory, having been driven from the surface, strike inwards; so that we are at present informed that the most serious inflammations of internal organs are nothing more or less than efforts by that wise goddess, Nature, to get rid of a blood poison! For what else does the elimination theory of pneumonia demand of us, but to recognise in a solidified lung, a great and perilous boil? for it is claimed to be essentially a great exudation, caused by inflammation, which was caused by Nature, to remove in

this exudation a materies morbi which preëxisted in the blood. If this is so, we cannot recognise too clearly the important fact, for by it we learn the true nature of much disease besides pneumonia. Thus, out of a certain number of patients who are admitted into a hospital, all sick from the same exposure to an eastern storm, the first has pneumonia or pleurisy; the second, cystitis; the third, general rheumatism; another inflammation of the bowels; and another acute nephritis. What is the connecting link between so many internal inflammations produced by the same cause? Our pathologist answers, we have here certainly a blood poison, generated most likely by suppression of the excretions of the skin, and circulating everywhere, till perturbed Nature sends it to be thrown out in one case by the lungs, in the other case by the kidneys. We ask, is it also sent for elimination to the mucous surface of the bladder, or to the lining membrane of the heart? Is it not rather due to a general alteration in the blood and in the functions, whose effect is therefore manifested in these parts, which have relatively less power to resist the injurious influence of such alteration, than due to an erratic effort of Nature at elimination. For, let us cite another instance:

A laboring man meets with an accident which presents the surgeon with a case of compound fracture of the thigh. On the third or fourth day, along with the reaction and strong inflammation set up in the injured limb, the patient passes into a raving delirium. Very soon a watchful observation reveals the dreaded presence of a surgical pneumonia? Now what is this pneumonia. Is it from pyæmia? Certainly not, for a sufficient time has not elapsed for a true septic infection. The inflammation about the fractured bones in the thigh is not eliminating anything in particular; why is the same inflammatory process going on in the lung, and which would have never occurred any more than the swelling of the leg, but for the accident, an eliminative and conservative process of nature?

This elimination theory is, in fact, based on the *word* Nature, which is nothing more than a word; for in itself it can no more be the cause or explanation of anything, than such words as catalysis or allotropism can be explanations of chemical phenomena. Thus, let us examine the idea of the intelligently conservative course of Nature in creating a pneumonia. Is it conservative to choke up such an organ as the lung with a depurative exudation? Is it true that the more extensive and complete the solidification, the better the blood is cleared from a dangerous ingredient? We ask, what worse mischief could it do anywhere else? We think that, if the pneumonia poison were circulating in us, we would rather not have it eliminated at all, but take our chances; for it is hard to see what more undesirable place it could find to settle in than the air-cells, unless it went to the brain. But, after all, we are not sure that the elimination theory will not follow us even there, so that we will find our pathologist, as he stands by a case of encephalitis, admiringly contemplate the conservative processes of Nature, in getting rid of a blood poison. All we can say is, that such pathological conservatism reminds us of the familiar political conservatism which was so anxious for the preservation of the Constitution of the United States as to advocate a general secession.

Additional Powers Conferred upon the Metropolitan Board of Health.—A bill, conferring upon the Metropolitan Board of Health the exclusive power to grant licenses for the sale of liquors within the said district, was passed by the Legislature, March 29, 1863.

A CASE OF

ENTIRE DISLOCATION OF THE CLAVICLE.

By N. L. NORTH, M.D.,
BROOKLYN, NEW YORK.

On the 26th of January, 1863, I was called upon by Mr. M., who stated that his son, a boy of about fourteen years of age, during his sports with his playmates, had been thrown backwards from a stool or slight eminence, upon which he had been placed, and came down striking with his whole weight upon the back of his left shoulder.

Upon examination, I found as a result of the fall a deformity as follows:

The shoulder depressed and thrown forwards; the centre of the clavicle fallen in as if fractured, with an abrupt, rounded prominence at the sterno-clavicular articulation, and a sharp, prominent ridge on the top of the shoulder, standing some three-fourths of an inch above the superior point of the acromion process, and running from that process towards the neck for about an inch, then gradually tapering down to the usual form of the neck. The boy complained of a great amount of pain and considerable difficulty of breathing.

The father, expressing great anxiety, asked if something could not be done to relieve his son.

My examination of the case led me to the inevitable conclusion that the cause of the deformity was an *entire dislocation of the clavicle without fracture*, both ends, with of course the entire bone, having been slipped, or more expressively, "popped" out by the force of the blow or fall upon the shoulder, and then drawn half way over forwards and downwards by the action of the large pectoral and deltoid muscles. The round prominence in front was caused by the turning *out* of the sternal end of the bone, and the sharp ridge on the top of the shoulder was caused by the turning *up* of the trapezoid portion, while the depression in the centre was the effect of the turning *down* of the convexity at the middle portion of the clavicle.

I adopted a treatment as follows: Forcibly throwing the shoulders backwards, and retaining them in position with long strips of adhesive plaster applied in the form of the figure of 8-bandage, I then made compression with my right thumb and finger backwards and downwards upon the trapezoid portion of the clavicle; and at the same time, with the thumb and finger of my left hand upon the sternal end of the bone, made firm pressure upwards and backwards. I had the satisfaction of *feeling* the ends of the bone return to their normal positions, and of *seeing* the supposed *fractured* portion of the bone round up in its position, completely restoring the proper shape and symmetry of the parts. I then applied compresses successively to each end of the bone, retaining them by means of adhesive straps; and as a help to my dressings, and to assist in retaining the whole in position, I applied Day's "neck-yoke" apparatus for fractured clavicle. In the course of two weeks I cautiously commenced loosening the dressings, and at the end of three weeks I removed them altogether and discharged the patient well—since which time he has had no difficulty whatever with the shoulder, and there is now but little if any trace of the accident remaining.

Since his recovery the patient has been seen by a considerable number of medical gentlemen, among whom I may mention Prof. W. Parker of the College of Physicians and Surgeons.

The above I consider as a rare case, as I have not in my reading been able to find a record of a similar case; and I have yet to meet the surgeon who has

seen and recognised any other example of an entire dislocation of the clavicle without fracture.

A CASE OF STRANGULATED CONGENITAL INGUINAL HERNIA IN THE FEMALE.

SUCCESSFULLY OPERATED UPON

By JAMES H. ARMSBY, M.D.,

PROFESSOR OF ANATOMY IN THE ALBANY MEDICAL COLLEGE.

The patient was a child, three years old, a daughter of Mr. S. C. Foster, of Rensselaer Co., N. Y. Immediately after her birth, it was discovered that she had *inguinal hernia* on the right side, and by the advice of the attending physician her parents procured a truss, which was applied, and appeared to answer the required purpose.

On the morning of the 3d of January I was called upon to visit the child by Dr. Allen, of Greenbush. On examination, the hernia was found presenting directly over the pubic extremity of Poupart's ligament. Attempts had been made to reduce it, but without success, and anodynes and warm fomentations had been ordered.

It was now seventy-two hours since the first symptoms of strangulation had appeared, and the child's condition was extremely serious. She was greatly debilitated by the pain and constant vomiting, was perspiring profusely, her expression was pale and cadaverous, and her pulse was 160.

The operation was immediately performed in the way ordinarily practised for strangulated hernia in the adult. The parts were greatly swollen and congested, and about three inches of the ileum, not far from the *caput coli*, were found protruding, completely strangulated and *gangrenous*. The portion of intestine involved adhered firmly to the sac and surrounding soft parts, and was soft and partially disorganized.

Seeing no chance for any other result than an artificial anus, I left the gangrenous portion of intestine as I found it, and applied a linseed-meal poultice. Before the next morning it separated, and fæcal matter escaped freely at the opening. Contrary to my expectations, the patient improved rapidly under the use of anodynes and tonics; the wound gradually contracting until the twelfth day after the operation, when she had a natural evacuation from the bowels, and no more fæcal discharge from the opening. The wound healed kindly, and one month after the operation the cicatrization was perfect, and the patient restored to her usual health.

I have never before met with a case of congenital inguinal hernia in the female; and I think such cases must be rare, as Dr. March informs me he has never seen one, and does not remember ever having heard of such a case before. Several medical gentlemen were present at the operation, and we were all convinced that from three to three and a half inches of the entire intestine was included in the stricture, and came away by sloughing.

The efforts and results of Nature, in forming the new channel, illustrate her power and fertility of resource.

Mr. Baker Brown has just been elected a member of the Medical Society of Christiania, in recognition of his services in operative surgery.—*Lancet.*

Decline of the Cattle Plague.—The cattle plague is reported to be on the decline in England.

Original Lectures.

ON CHOLERA.

By A. CLARK, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

Lecture III.

The Theories in regard to the Origin and Spread of Cholera. How is this Poison introduced into the System, and how does it operate after it has been introduced? The Character and Composition of the Vomit and Evacuations.

In the consideration of cholera, the next point which may occupy our attention is its cause, and the mode in which that cause operates upon the system. There are various theories in regard to the origin and spread of the disease. One of these assumes that it is contagious, communicable from person to person—that it is a zymotic disease; that the zyma or ferment is the special cholera poison, that it finds its way into the blood, and then rapidly causes zymosis (fermentation), thus multiplying itself; then not only produces that terrible commotion in the individual which we have lately reviewed, but also diffuses itself in the air which surrounds him, to be received into the bodies of other persons and work the same mischief in them, and in them again to be reproduced.

Another view is that the disease depends upon some peculiar condition of the atmosphere, denominated "epidemic constitution;" and that this epidemic constitution of the air is widely diffused over a given country; but of itself alone, while it predisposes to cholera, does not produce it, requiring the aid of certain local influences, or "localizing conditions," these localizing conditions being filth, crowding, and other well known sources of insalubrity.

Another theory, that of Dr. Snow, assumes that the disease is a communicable one, but communicable in a particular way. He thinks that the poison is produced in the alimentary canal, and that it is voided with the evacuations, and that these evacuations may contaminate the water that we drink, or by unclean hands the food that we eat; and so the poison comes in contact with the intestinal mucous surfaces, and directly provokes the cholera symptoms. In this view physicians are less liable to cholera than nurses, because they are more likely to eat with washed hands.

Dr. Thiersch attempts to show that the cholera discharges are not poisonous when they are first voided; but that after a certain length of time, from three to five days, if the temperature be anywhere in the neighborhood of fifty degrees Fahrenheit or above, they undergo a fermentation or decomposition, and that in this state they are poisonous and will reproduce cholera. He assumes that after a given time, six or eight days, this fermentation has ceased, and the evacuations have then become innocuous.

The views of Prof. Pettenkofer on the propagation of the disease are now attracting particular attention. He does not admit that the alvine evacuations are poisonous when first discharged; nor yet that they of themselves undergo any fermentation or change of any kind that makes them so, but that the poison is the result of two distinct agencies—the discharges and the soil. In the words of Dr. Weber, an expounder of this doctrine,—for the epidemic spread of cholera, "the only indispensable conditions are human intercourse, yielding the germ in the excretions of cholera patients, and the soil develop-

ing the germ into activity. The qualities of soil considered necessary for the development of the cholera germ are: 1st, that it be porous—that is, permeable to air and water; 2d, that water exist at a certain depth below the surface (ground water or subsoil water); 3d, that the soil be to some degree impregnated with the products of organic decomposition, especially those of excrementitious origin." In this view it is understood that all the members of the large Bavarian Commission for the investigation of cholera, in 1854, concur. It is stated that they found the disease prevailing epidemically only on such soils as are here described; that localities of "impermeable rock were either entirely exempt or only exhibited isolated cases." Temperature, the dryness or moisture of the atmosphere, and elevation of site, are of little importance. The intestinal secretion and the soil are the parents of this hideous offspring. The moisture required for this generation is derived by inbibition and evaporation from the "ground-water;" by which term I understand the water that supplies wells and springs, which is at different depths in different places, and in the same place at different times, "from about five to fifty feet," "the first *stratum of water* beneath the surface." The theory claims that where this "stratum of water" is nearest the surface of the ground, there the soil is most prolific of the poison; that elevation is of no avail, unless the layer of earth underneath the soil, which is impenetrable to water, has less acclivity than the surface, leaving the "ground-water" on the hill at a greater depth than in the valley; that the period of the subsiding of the "ground-water" is the most dangerous, the time of the greatest activity in the soil agencies, and that this subsidence usually occurs in July, August, or September, when cholera is commonly most prevalent, if not most fatal, or in the words of Dr. Weber, "makes its greatest ravages."

There is also a theory claiming that the presence of cholera depends upon the influence, negative or positive, of ozone; another, that it depends upon the withdrawal of a considerable portion of the atmospheric electricity; still another, that it has a fungous origin. The fungus, according to Dr. Mitchell, is produced outside the body; and its spores, or some other emanations from it, enter on the breath and so produce their poisonous effects. According to Messrs. Brittan and Swayne, there is a "cholera fungus." It is assumed that this is generated in the intestinal canal, and that when it is discharged it is capable of reproducing the disease if it enters another human body. This hypothesis, if admitted, would give precision, and perhaps demonstration, to Dr. Snow's theory.

One other theory is to be considered. It is the doctrine of the miasmatic origin of cholera. It recognises a zyma and zymosis, not within the human body, but in the air or in the soil. It looks upon the cholera poison as having an origin analogous to the origin of the miasm which produces yellow fever. You will pardon me, therefore, if I make a digression for the purpose of illustrating this opinion. Yellow fever is not a spontaneous disease in the Northern cities of the United States. It never has occurred in New York, or Philadelphia, or Norfolk, except when its own particular miasm, generated elsewhere, has been brought to those cities. It has not always, or perhaps commonly, spread or become epidemic, even when infected ships have brought the poison into their several harbors. The air of the ship may be noxious, and those who go on board and breathe the atmosphere of the cabin or hold may contract yellow fever; but that the outside air become poisonous, certain conditions are necessary. What these conditions are, is not perfectly known; but being present, the poisonous air of the ship becomes a ferment, and, by some catalysis in the earth or air, produces its like. Then is yellow fever epidemic, and continues to be so while these conditions remain. This doctrine seems to be as nearly demonstrated in the Northern cities as any medical doctrine can be; and for New Orleans, Mobile, Charleston, Savannah, and other Southern towns, the last five years have done much to enforce and illustrate its truth. In the same way it is believed cholera may be produced and diffused. Not that there is any approach to identity in the composition and character of the two poisons when generated, but that the process by which they are generated is analogous. Here the parallel ends. This theory embraces another element entirely unknown to any hypothesis applicable to the cause of yellow fever. It assumes an "epidemic constitution" which generally goes before and announces the coming of cholera, and that by this particular state or condition of the air, or earth, or electricity, or ozone, or whatever else it may be, there is produced a predisposition to an attack. It also recognises "localizing conditions," or insalubrity, not as a generator of cholera poison directly, but as loading the air with other poisons which aid the cholera miasm in its fatal work. What the constitution of this subtle destroyer is, the hypothesis does not attempt to explain. Drs. Baly and Gull think it has a consistence that causes it to adhere to inanimate things, so that with them it can be transported from one place to another.

There are those who believe that cholera is a miasmatic disease in the sense in which I have just used the term, and that it is also contagious.

These, I believe, are the principal views that have been entertained regarding the origin and spread of cholera. All of them recognise a special, perhaps I should say a specific poison; and indeed it seems difficult to survey the history of the affection and not believe that it is produced by a poison of its own.

Now, then, how is this poison introduced into the system; and how does it operate after it has been introduced? I suppose the first of these questions cannot be confidently answered; perhaps through the surface of the body, by absorption; perhaps it is received into the alimentary canal with our food, and is there absorbed; probably it is introduced into the lungs in breathing, and so contaminates the blood. In one way or another it seems to me that this poison does operate first through the blood, and, circulating with it, by some vital affinity, soon begins to produce its specific effects through the nerves of the ganglionic system, and particularly the ganglionic nerves of the abdominal cavity. This, you will say, is a theory. I admit it; but it has the support of a strong probability. I have already told you that the examination of the ganglia of the abdomen has not revealed any constant lesion. Indeed, in the greater number of cases, the statement of observers is, that nothing unnatural has been found. But this does not in any manner invalidate the hypothesis. A thousand changes in the innervation are produced without sensible alteration in the nerve-centres from which these perverted influences emanate. If, for example, an over-dose of strychnine has been taken and absorbed into the blood, it will in a short time manifest its poisonous influence through the medium of the spinal cord; the person dies; you examine this nerve-centre; it appears to be healthy; there may be a little more blood in it than usual, but that is all you can discover. Or it is a poisonous portion of opium; the person dies through the vital affinities of the opium for the brain; you examine, after death, and find the veins of the brain full of blood; but you find nothing else. You call the microscope to your aid, and find the brain cells natural and healthy. And so it will be after the use or abuse of any of the drugs that have what is

called vital affinity for any nervous system or centre. It does not, then, negative the proposition that this portion of the nervous system is the great centre, the *primum mobile*, in the disease, that we cannot discover anatomical changes. You have been informed in another connexion, that when the nervous relations of the eye with the ganglionic system are destroyed, that organ becomes inflamed and is soon disorganized. Electricity may temporarily suspend this destructive process, as it will dissipate the inflammatory hyperæmia. It seems to be the conviction of all physiologists that the circulation in the capillary vessels is greatly under the control of the ganglionic centres; and of the pathologists, that the inflammatory process is dependent on disordered innervation in the same nervous system. The accepted doctrine is, that the more vigorous this nerve force, the more the vessels are contracted; the less forcible the nerve current, the more they will be expanded and congested. If these centres are temporarily paralysed, there will be nothing left to modify and regulate the power of the heart in these expanded and passive tubes. This condition, or an approach to it, is what I believe occurs in cholera. The regulating power is lost, and the blood is poured into the intestinal vessels in an unusual tide, and the transudation of its watery and saline constituents is demonstrated in copious alvine dejections. The stomach is similarly affected in most cases, and the result is substantially the same.

But this is not all. The degree of collapse and depth of prostration are not measured by the loss of the blood constituents alone. The collapse may follow one or two evacuations as well as thirty or forty; may occur indeed, in rare instances (Dr. Gull's case), where there has been no characteristic discharge, and where but little of the rice-water material is found in the alimentary canal after death. In truth, so little is this relation a fixed one, that there are sound observers who regard the discharges as eliminative and salutary; and it is well known that the danger is not proportioned to the number of stools which preceded the collapse, but the reverse, at least within certain limits. There is abundant testimony to sustain the proposition of Prof. Parkes, that "exclusive of the mildest forms of the disease, a case with little vomiting and purging is more malignant and more rapidly fatal than one in which these are prominent symptoms." Then the collapse of cholera differs from the prostration which follows the loss of blood in many important respects. The blueness of the skin, the less frequent pulse, the muscular strength, the sense of burning while the parts are actually cold, the general anæsthesia which affects a few, and especially the rapidity of the recovery when that result occurs, belong to cholera, and make a broad distinction between these two conditions. Dr. Johnson has lately called attention to this point in his Notes on Cholera. There is, then, in the cholera collapse something besides the effects of blood depletion. The marvellous but temporary effects of injecting saline solutions into the veins of the collapsed may seem to argue otherwise. The resuscitation is indeed wonderful; but, whatever may be its bearing as an argument in those who have lost a great deal of the fluid of the blood, it can signify little for those who have not sustained such loss. What shall we say, then? Is there not evidence of great perversion of the ganglionic nerve-force everywhere? Are not the perverted sensations evidence that the cerebro-spinal system feels the effects of the poison, at least secondarily, through its connexions with the sympathetic? To my mind these questions must be answered in the affirmative.

The cramps, at first view, seem to suggest that the spinal cord may be also primarily affected by the poison, or that the muscles are unhealthily stimulated by the poisoned blood; or, as it is sometimes claimed, that the thick blood tardily moving through the vessels, in some way provokes muscular contractions. But neither of these suppositions appears to me called for. It is not many weeks since a member of my own family had cramps of the same kind as those that occur in cholera, and as painful as they are in the cases of average severity, lasting all night and part of the next day, attending undue purgation by one of the common mineral waters. Cramps are a common attendant on our indigenous autumn cholera, although in that disease there are no rice-water discharges, and no collapse—at least none that can be compared to the collapse of the Asiatic cholera. Then, too, in some at least of the rapidly fatal cases of Asiatic cholera, in which the purging is inconsiderable, the involuntary muscular contractions do not occur. These facts, then, point to the nervous connexions of the intestines and the spinal cord, on the one hand, and those of the cord and the muscular system on the other. They pretty clearly show that, but for the diseased action in the alimentary canal, there would be no cramps. The cramps, then, I cannot doubt are the result of reflex excitement and reflex action.

It does not appear, perhaps, when a person dies in eight, ten, or twenty hours, that there is an inflammatory element in the intestinal hyperæmia—that it is not a mere passive congestion; but if you will recur to those illustrations and specimens exhibited at our last meeting, it seems to me that you cannot fail to persuade yourselves that the end of this diseased action is a kind of inflammation. It yields no organizable product; there is rarely any purulent matter; but there is an action analogous to that in œdematous laryngitis, and to that in diphtheria. There is the forcible distension of solitary glands. You say this may occur from mere imbibition. I do not think so. It never occurs when the intestines are filled with fluid, and there is no hyperæmic action. It occurs in small-pox, but not without inflammatory injection of the mucous membrane. Authorities are not wanting in support of this view. As early as 1832 the late Prof. Horner, of Philadelphia, recognised it; at least, I so interpret the long and valuable paper which he wrote on the cholera of that year. He observed the membranous patches and the enlarged glands. Cruveilhier, whose illustrations of lesions in the disease you examined when we last met, at the same early period, hardly falls short of admitting it. He says: "Anatomy and pathological physiology unite in demonstrating, in a manner not less peremptory, the *great affinity* which exists between the mode of fluxion which results in the seromucous secretions of cholera and the mode of fluxion which constitutes inflammation; so much so, that many individuals who die of cholera after reaction, exhibit unequivocal traces of inflammation." But I will not quote opinions; I prefer to leave on your minds the influence of facts already presented, which, as they are the only basis of opinion, are above all written authorities.

I now return to Dr. Johnson. You will remember that while I called attention to the question of the extreme anæmia of the lungs in the stage of collapse, I was not able to cite authority beyond that of Dr. Johnson himself, which was conclusive. But the other cardinal fact of his theory, the fulness of the right cavities of the heart, must be admitted. It has been noticed from the first pathological examination of the disease. Dr. Johnson, considering these two points as settled, claims that "the arrest of the blood in the branches of the pulmonary artery," "the minute branches, *before* it

reaches the pulmonary capillaries," "is the true key to the pathology of the choleraic collapse." "The blood," he says, "contains a poison whose irritant action upon the muscular tissue is shown by the painful cramps it occasions; the blood thus poisoned excites contraction of the muscular walls of the minute pulmonary arteries, the effect of which is to diminish, and in fatal cases entirely to arrest, the flow of blood through the lungs." This doctrine he thinks explains the fact that blood, in many cases, does not flow from severed arteries—the blueness and coldness of the body, the sunken eye, the shrivelled features, the feebleness of the pulse, the suppression of bile and urine, and the continuance of the secretion in the female breasts. This last fact he accounts for thus. The chief constituents of milk "may be obtained from the blood without the addition of oxygen. The secretion of milk, therefore, continues during the stage of collapse, while the highly oxygenized secretions are suspended." He claims for his theory the support of experiment. A dog is killed by injecting into his veins a concentrated solution of salt and soda, or a few grains of the nitrate of silver in solution; the right cavities of the heart are found distended, the left nearly empty (Blake), &c. But I have stated enough of this new view of the cholera collapse to interest you in the perusal of the "Notes on the Pathology and Treatment of Cholera," which you will find written with great thoughtfulness and ability. The theory must be subjected to the test of new pathological researches.

Postponing for a short time the more critical examination of the theories which claim to explain the propagation of cholera, we turn now to examine a little more closely the evacuations derived from the blood. The vomit has not always the appearance of "rice-water;" as I have already intimated, it is variable in color, sometimes green, sometimes of a dark hue, sometimes yellow. With reference to its chemical reaction, one of the striking things that I have nowhere seen taken particular notice of, is the tendency in the discharges and fluids of the body to become acid. You would expect to find an acid fluid in the stomach; and in all instances where the vomit has been examined, it has been found either acid or neutral, never alkaline. Becquerel found in one instance in the vomited fluid as much as thirty-one parts of albumen in the thousand; but in five other examinations it was found in proportions varying from a trace to eighteen and a half parts in the thousand. In this respect the fluid vomited is far from having the constitution of the serum of the blood, taking that which results from spontaneous coagulation as the standard. The chloride of sodium was found in the proportion of from two and a half to eight and a quarter parts in the thousand in the fluid. Thus this constituent was sometimes but little more than half as much as is found in healthy serum, and sometimes twice as much. But the great part of the material ejected is water. In a single instance the same observer found the water to amount to only nine hundred and thirty-one parts in the thousand, leaving sixty-nine for the solid matters. But in general the quantity of water varied from nine hundred and fifty to nine hundred and ninety-one parts; so that the water in proportion to the solids exceeds, and in most cases very greatly exceeds, the water of the serum.

With reference to the stools, they were found to contain from nine hundred and seventy-eight to nine hundred and eighty-eight parts of water in the thousand, preserving a more even average than does the material rejected from the stomach. Common salt has been found with great uniformity in the dejections. Dr. Hutchinson found it in considerable quantity. Becquerel, in four examinations, makes the proportion $3\frac{7}{10}$ to $7\frac{8}{10}$ in the thousand parts. Albumen has not generally been discovered in this fluid. A trace of it has been reported. Becquerel found in one instance $4\frac{5}{10}$ in the thousand parts, but in general there is nothing that responds to the tests of heat and nitric acid, or that has been recognised as albumen by the greater number of observers. M. Mialhè reports that the albuminous element is to be found in the evacuations in the form of albuminose; and he discovers it, not by the tests usually employed for the detection of albumen, but by alcohol, the salts of lead, mercury, and silver, and he asserts that the quantity is considerable. He regards the transformed albumen as the product of a change in the albumen and fibrin of the blood and of the tissue metamorphosis. M. Baudrimont, in a paper lately read before the Academy of Sciences, Paris (*Richmond Med. Jour.*, March, 1866), seems to have found albuminoid matter in the evacuation, and thinks that it has the character and gave the reacts of *diastase*, such as is formed in malted barley, and he seems to have concluded that this diastase had taken the place of albumen even in the blood. These chemical points are not in the line of my present studies, and I cannot aid you much in judging of their correctness. All new opinions should, however, be received with caution, especially if they have a practical bearing. This at least may be inferred from these chemical examinations, that the evacuations are not composed of the liquor sanguinis, nor yet of serum as it is found after the coagulation of blood, but that their chief ingredient is water derived from the blood, containing certain saline matters, of which common salt is the most abundant, the proportion being generally greater than in the healthy blood. The phosphates of lime and soda and sulphates are discovered, but each in proportion less than one part in the thousand, and carbonates in scarcely appreciable quantity. We further learn that the draft made on the albumen of the blood is not very heavy, since all the solid matter in the filtered discharges is not above eight to fifteen parts (Becquerel), and the saline substances constitute a large portion of this; while in the healthy blood the albumen is rated as about seventy parts in the thousand.

Bile has generally not been found in the choleraic evacuations. Almost every observer who has turned his attention to this particular point has failed to find it. Prof. Parkes, of London, following some investigations of Mr. Simon, has come to a different result. He states that there is bile in the evacuations of cholera at all times except during the very height of the disease, but that it is found in a modified condition; that it does not give the usual colors upon the application of nitric acid, but that it does give a pink, violet, or purple color when nitric acid in small quantity and heat are used together. He says he has found this same condition of the bile in the fluid discharges of typhoid fever with a good deal of uniformity; that he has occasionally found it in other conditions of disease, and even in the healthy evacuations.

An interesting little study has been made quite lately, quoted in the last number of the *Journal of Medical Sciences*, by Dr. George Johnson, regarding the nature of that material which gives the opaline or milky appearance to the choleraic discharges. Dr. Johnson reports that all that whitish material that is seen in the rice-water discharges is epithelium in flakes, or single cells, which seems to have exfoliated from the alimentary canal. I have already told you that this epithelium is dislodged early in the disease, as it is in other inflammatory processes; and this observation of Dr. Johnson is supported by a reputation which will not permit us to doubt its correctness.

He further says that the quantity of epithelium is so very large, that there must be, during the cholera process, a power of reproducing it as it is removed; and then suggests that it is possible this reproduction, layer after layer, is one of the agencies by which the special poison is to be eliminated from the body.

The choleraic discharges are not, like the natural discharges from the intestinal canal, always alkaline; in the majority of cases they are found to be either neutral or acid. In yellow fever there is a period that Dr. Blair, of Demerara, has denominated the period of acid elimination. There seems to be a period of acid reaction in cholera.

The color of those discharges varies, as does the color of the discharges from the stomach. They are not all "rice-water," but are frequently dark, frequently yellow, and may be of a mahogany color. Dr. Hutchinson found in ninety-three cases observed in the last epidemic, that thirty-six had yellow or mahogany-colored discharges; and that among them there was the greatest mortality. The stools are not always fluid. I remember a fatal case, occurring in the epidemic of 1854, in which they had the consistence of a soft jelly, and the color of boiled starch. Among the most fatal cases are those in which the blood, staining the dejections, gives them a brighter color than it does to the mahogany discharges; these have been called "red-currant-jelly stools."

The increased specific gravity of the blood, and the increased proportion of solid to fluid matter; its tenacious character, its dark color, and its imperfect coagulation in cholera—are points which require no further investigation. But beyond these, there are some facts which we may profitably consider. Dr. Stevens, when he proposed the saline treatment, believed that the salts were greatly withdrawn by the discharges. Dr. O'Shaughnessy came to the same conclusion from his chemical investigations; but Dr. Garrod, of London, found that there was more weight of saline constituents in the choleraic than in healthy blood, taking pound for pound. In the serum of the healthy blood the total salts are represented in the mean by 5.60 in a thousand parts for males, and 6.80 for females. In choleraic blood 5.70 in the thousand is the lowest proportion obtained by him, and 10.70 the highest. So the proportion appears to be decidedly greater than in the healthy blood. Dr. Robinson, of Edinburgh, infers from his own examination and from others made in that city, that 9.70 : 1000 will best represent the quantity of salines in the blood during the early stage of cholera—9.20 : 1000 in early collapse—9.10 : 1000 in collapse, and 8.40 : 1000 in the reaction. These figures do not indicate proportional reduction in any stage, but rather excess in all. The comparative reduction in the period of reaction is probably due to the partial restitution of water at a stage when fluids are again tolerated by the stomach. This would seem to suggest that the saline treatment is not necessary, at least for the replacement of the salts. The chloride of sodium is drawn off in largest quantity, and it may appear that while the other salts abound, there is deficiency in this. Becquerel, however, found in two examinations of cholera blood that the proportion, even for the chloride of sodium, was high, viz. 6.61 : 1000.

That there should be chloride of sodium in the dejections, often in larger proportions than are found in the healthy blood, and yet that the blood from which it is withdrawn is still overcharged with this salt, would hardly be looked for. The urine, in health, is constantly abstracting it from the circulating fluid, at the rate of about five parts per thousand of the secretion, or about one-seventh of an ounce a day. The suspension of this secretion would account for some accumulation in the blood, if there were no other outlet for it. The water, yielded by the blood for the dejections and matters vomited, appears to carry with it its full proportion; for, though sometimes less, it is often more. Will the suppression of urine, then, account for the supposed excess in cholera blood? Or is Becquerel's report to be revised. Corenwinder gives the results of four examinations of cholera blood taken from the body after death, as follows:

Chloride of sodium,		1.85,	water,	543.28
"	"	2.74	"	751.10
"	"	2.12	"	751.10
"	"	0.69	"	710.00

The question of deficiency or excess, then, so far as the common salt is concerned, is not definitively settled.

Another interesting point associated with what I have already stated in regard to the chemical reaction of the fluids, is that the blood itself often becomes neutral, and even acid. I need not tell you that its natural reaction is alkaline. It has been generally assumed that this alkaline condition is preserved by the carbonate of soda, and that it is lost by the withdrawal of this salt. Dr. Garrod expresses doubt regarding the existence of this carbonate in healthy blood, and thinks it more likely that the alkalinity is preserved by the tri-basic phosphate of soda, and that that salt may undergo such changes in constitution as to produce the neutral or acid state.

The presence of albumen or albuminoid matters in the evacuations must diminish the absolute quantity of albumen in the circulation; but whether this loss disturbs the proportions in the remaining blood can only be determined by analysis. Becquerel and Garrod both report that in cholera blood the albumen falls below the standard of health. Becquerel found 51.80 and 69.53 parts in the whole blood; Garrod 103 parts in the serum, instead of 125. It appears, then, that the water and the albumen are drained from the blood so as to leave it impoverished as to these constituents, though in very different degrees. This result would hardly be expected in the albumen when we remember how small a proportion of it or its analogues is found in the evacuations, and may lead to further examination of Baudrimont's statement, that the albumen of the blood is converted into diastase. If this is true, the albumen tests may not be adequate to settle the whole question.

Urea is found in the blood of cholera, but not in the early stages. Garrod found it as follows, viz. in one case during collapse, 38 : 1000; after death, 0.92; in another case where, after partial reaction had taken place, the patient had fallen into a semi-comatose state, 0.65; in a third, during reaction, 1.14. The reason offered for the slow accumulation of this substance, after the kidneys have ceased to act, is, that in the shock of cholera the tissue transformations are probably slow, and the amount of urea formed is consequently small. Uræmia, in fact, is the immediate cause of death in only a small proportion of the cases, although it may favor the inflammatory complications of which many die in the fourth stage.

The urine, you are already aware, is suppressed in the great majority of cases when the violent symptoms of cholera begin. It continues to be suppressed until reaction, and it was then found by Dr. Begbie of Edinburgh to be more or less decidedly acid in fifty-nine out of seventy-two examinations; neutral in seven, and alkaline in six. It was found to be albuminous in fifty-three cases out of sixty-seven; and contained casts of the secreting tubes of the kidneys in twenty-four out

of sixty-four. In almost all, he says, there appeared to be broken fragments of casts, which are quite as significant as unbroken casts; so that it is fair to infer that there is a process going on analogous to that which, when confirmed and completed, constitutes Bright's disease. The urine contained bile in forty-three cases, the indications being decided in twenty-eight out of sixty-eight. The urea is materially diminished. Dr. Begbie assumes that thirty parts in the thousand is the normal quantity of urea in urine; and he finds in nine cases of cholera the quantities to be severally twenty-eight, twenty, nineteen, eighteen, eleven, ten, nine, eight, and one-and-a-half; in most, very materially, and in some only moderately diminished. These examinations were almost always made in the first of reaction, when the urine was beginning again to be secreted; in a few instances it was drawn by a catheter after death. The specific gravity varied between the minimum, 1007, and the maximum, 1045; in the greater number it was about 1012. This author reports that, as the urine became more abundant in this stage of reaction, the albumen disappeared, showing, it would seem, that its presence was the result of the choleraic shock; and yet I see it stated that M. De Wouves "has *demonstrated* that albumen can be found in the urine of *all* cholera patients some days before the more serious symptoms exhibit themselves." M. De Wouves must have had rare opportunities, such as few physicians enjoy, to be able to *demonstrate* such a proposition. If it be found to be true, it will certainly be a valuable addition to our knowledge.

THE MEDICAL RECORD.

AMERICAN MEDICAL ASSOCIATION.

THE next meeting of the American Medical Association is to be held in the City of Baltimore, on Tuesday, May 1, 1866.

The influence for good which these annual assemblages have upon the profession, is sufficiently manifest. This fact must be admitted by all who have watched the growth of the organization since 1847. Springing into an existence by the efforts of, so to speak, a mere handful of men, it has since then so effectually gained the confidence of the profession, that all important questions are now referred to it, and its code of ethics is universally observed and respected by every well ordered society.

In view of the great benefits which it has already conferred upon the profession the question naturally suggests itself, in connexion with the next meeting, whether this usefulness can be increased.

The answer can be made without much hesitation, when we consider the necessity which has existed since the very foundation of the Association for a proper, efficient, and comprehensive plan of organization. It has long been acknowledged, even by its founders, that the Association has fallen far short of its original design, and the principal reason for this has been confessed to be the want of a remedy for certain defects in its system of government. The objections which are now found to exist in regard to the efficiency of the original plan, could not at the time it was drawn up be foreseen or provided against. It was only after the Association had gained a certain amount of experience in self-government, that these difficulties began to increase, and it was not long since deemed necessary to have the Constitution most thoroughly revised. This task was undertaken by Dr. N. S. Davis, of Chicago, and the alterations which he suggested were adopted at the last meeting.

But even those changes that were made fell short of the full accomplishment of their purpose. Notwithstanding the great care that had been exercised in preparing, as he thought, a model system of government, the attempt was in many respects a failure, as not a few important provisions which are yet to be made, and are absolutely required, were by him overlooked. As an evidence of this fact we might detail the number of amendments which were offered at that very meeting. It is true that only some of these are of great importance, while others refer to minor matters; but taken together, one cannot fail to recognise in them so many forcible arguments in favor of a more thorough re-organization. Not only do these objections to the present Constitution emanate from the members of the body, but we notice that some Medical Societies have taken the matter in hand, have discussed the propriety of offering certain amendments, and have given their delegates instructions in accordance with the decisions arrived at. This has been more particularly the case with the Philadelphia County Medical Society, a detailed account of the action of which has been given in our previous issue by one of our correspondents. The suggestions offered by this body are in the main exceedingly good, and we would commend them to the serious consideration of the members of the Association.

A fundamental change in the Constitution of the Society is much needed, and we are gratified to see so many indications of its being speedily and effectually consummated. There is probably no better opportunity than the coming one for effecting the objects sought after, as the meeting will no doubt be largely attended, and have representatives from every portion of our now united country.

We hope that all who go to the next meeting will prepare themselves for work during the entire session, and that not only this matter which we have more par-

ticularly referred to, but others which may be brought up, will receive due attention and consideration. There is no reason why the coming session should not be an eminently successful and profitable one.

The report of Inspector Newman, recently made to the Board of Health, concerning the condition of certain tenement houses in Mulberry street, is well calculated to give an idea how some of the poor of this city live. The many important points connected with drainage, ventilation, etc., which this communication covers, lead us to quote it entire. He says:

"These buildings consist of two front and one rear building, situated on a lot seventy-five by one hundred and thirty-four feet, which includes the alleys on each side of these houses. The two front buildings are six stories high, each from seven to nine feet in height, built of brick. The basements are entirely under ground, and dark; only one of these was inhabited. The dimensions of this basement cannot be given, as it was too dark to see the measuring figures or the outlines of the several holes in this domicile. The other basements were filled with dirt and ashes. These front houses are sixty by thirty-eight feet. The first floor is occupied by liquor and grocery stores.

"To the upper five floors are two distinct entrances, separating the building into two houses. The stairs and halls, each of which is thirty inches wide, leading up stairs, are mostly entirely dark, and admit neither light nor air.

"Drainage pipes are on the hall of each floor; the Croton water ascends only to the hall of the second floor. On each floor are four domiciles, which differ very much in regard to internal arrangements and size, as the houses are built very irregularly. Each family has one room, with one or two bedrooms, and some have no bedrooms, only a recess for the bed. For instance, in No. 9 the bedrooms have mostly a small opening leading into the dark hall; some have a regular window, and others no opening at all. The ventilation is therefore imperfect, and in many instances impossible.

"On one side of the second floor we find one family occupying a room 12 × 14½ feet, and two bedrooms, each 10×6. The room has two windows, and one bedroom only a small window opening into the hall. The ceiling is here nine feet in height. A bedroom on the fifth floor, 9 × 7 feet, has no window, and therefore no ventilation, the foul and vitiated air never changing. This apartment contains 224 square or 1,568 cubic feet. Suppose the family to be of six persons—which number, and even more, we often find in one family—then each person has only two hundred and sixty-one cubic feet of air, of which the largest part is poisonous. The rear building is four stories high, and was used formerly as a Baptist church. The stories range from six feet ten inches to nine feet in height. On each story are eight families. Each apartment consists of one room and a bedroom. In some cases the latter room is sub-let. The building is sixty by forty-two feet in width. There is neither drainage nor Croton water within the house. A dark passage way, thirty-five inches in width, divides the floors. The doors can only be found by the sense of feeling. The bedrooms have only one small window opening to the hall, and where they are broken the inmates have them closed hermetically with wood. Ventilation is entirely excluded from these premises. The whole building is in a dilapidated condition, extremely filthy, full of vermin, and has been known for years as a 'fever nest.'

"The population of these houses consists of three hundred and forty-one persons, in seventy-seven families, divided as follows:—Two front houses, five floors, four families on each, make forty-four families. In four stories four families, in basement one family, and floors in rear building are each eight families, make thirty-three, giving the total as above. The ground allowed to each person is twenty-nine square feet, in which calculation the alleys and yards are included."

Here is a simple detail of facts which are presented to us as the result of a thorough and careful inspection by a reliable man. But startling as these statements are we have the best of reasons for saying that they can, with slight and unimportant modifications, be made to apply to hundreds of tenements in this city. In fact, we may prepare ourselves for the contemplation of a still more appalling picture of misery when the notoriously filthy and densely populated Five Points is unearthed to the vigilant inspectors.

The necessity for a radical reform in the tenement house system has long been urged by the profession, but aside from offering advice in the matter they have felt themselves powerless to effect any good result. But may we not hope that the time for efficient action has arrived, and that the Health Board will apply the remedy which has been so long and urgently asked for?

Reviews.

THE RESTORATIVE TREATMENT OF PNEUMONIA, by JOHN HUGHES BENNETT, M.D., F.R.S.E., &c. Third edition. Edinburgh: Adam & Charles Black, 1866. Pp. 110.

THE object of the distinguished author of this *brochure* is to exhibit by numerous well collected statistics of cases of pneumonia observed by himself and by medical assistants under his supervision, the successful results of a special mode of treatment. The recorded data thus supplied are derived from a clinical practice extending over a period of sixteen years in the wards of the Royal Infirmary at Edinburgh. The treatment adopted by Dr. Bennett may be summed up in his own words:—"During the period of febrile excitement I content myself with giving salines in small doses, with a view of diminishing the viscosity of the blood," all of which is hypothetical. "At the commencement of the treatment I order as much beef-tea, milk, and other nutrients as can be taken; and as soon as the pulse becomes soft, solid food, and from four to eight ounces of wine daily. As the period of crisis approaches I give a diuretic, consisting of half a drachm of nitric ether, and sometimes ten minims of colchicum wine, three times daily, to favor excretion of urates. But if crisis occurs by sweat or stool, I take care not to check it in any way. I do not consider that the salines and diuretics do more than assist the natural progress of the disease. The essential part of the treatment consists in the rest, nourishment, and support given to the body throughout."

The conclusions arrived at by Dr. Bennett may be given as follows:

1. Simple primary pneumonia, whether single or double, if treated by the restorative plan, is not a fatal disease. Of 105 consecutive cases, 26 of these being double, occurring in all seasons, and diffused over sixteen years, not one case died. 2. As a general rule, prostration and weakening complications or remedies lengthen the period of

the disease, and also prolong convalescence. Women recover less quickly than men. 3. The amount of lung affected by pneumonia did not affect the result, for all the cases recovered, nor did it exert as much influence on the duration as is generally supposed; for, according to the author, "if only a fourth of one lung be affected, the recovery may take place in eight days; but after that, whether the half or the whole of one lung, or two-thirds of both lungs be involved, it does not appear to cause much difference." 4. Since the observations of Louis, it has been supposed that a pneumonia at the apex of a lung was more fatal and more prolonged than one at the base; and so it may be with an antiphlogistic treatment. But with the restorative practice, these statistics show that in eleven cases in which the disease was confined to the apex, recovery took place in all. 5. In no single instance did a case of acute pneumonia degenerate into the chronic form, or become gangrenous. 6. Deaths only occurred from severe complications, and Dr. Bennett is disposed to believe that under a restorative treatment, begun early in the case, the influence of age and sex on the mortality is not appreciable. Neither is the duration of the disease much affected by complications, so long as the general health is not impaired.

The author next considers the comparative statistics of results of treatment. Without citing the mass of materials embraced in this paper, gleaned from the experience of European and American physicians, we may briefly quote the comparative degrees of mortality attendant upon each mode of treatment.

An extreme antiphlogistic treatment has always been attended with a large mortality, amounting to one death in three cases; but when modified in various ways —that is, by diminishing the amount of lowering remedies, selecting cases, or by the cases being those of young and vigorous subjects—the mortality varies from one death in 4½ to one in thirteen cases.

When one-half the cases are those of children, or persons below twenty years of age, and the lowering treatment slight, the mortality diminishes to one death in 28 cases. A treatment by large doses of tartar-emetic has been accompanied by a mortality varying from one death in 4½ to one in 9⅙ cases. A dietetic or expectant treatment has been followed by a mortality varying from one death in 7¼ to one in 10.9 cases. In children, according to Barthey, the mortality is almost *nil*.

The results of a mixed treatment, according to the nature of the symptoms, have been a mortality varying from one death in 3⅓ to one in 13⅔ cases; while a treatment by stimulants was followed by a mortality of one death in 9 cases.

"The restorative treatment of the author having been attended by a mortality of only one death in 32¼ cases, is the most satisfactory yet published. But when it is considered that the four deaths resulted from pathological complications unconnected with the pneumonia, this treatment may be said to render the mortality in true cases of pneumonia *nil*. * * * It follows that supporting and restoring (not stimulating) the nutritive powers of the system, and avoiding all weakening remedies, ought to constitute the practice in pneumonia."

The rest of this able pamphlet is occupied in answering objections urged against this mode of treatment, and in the details of cases of special interest.

Disease a Part of the Plan of Creation. The Annual Discourse before the Massachusetts Medical Society, May 30, 1865, by Benjamin E. Cotting, M.D. Boston: David Clapp & Son, 1866.

A philosophical essay, replete with original views, and written in a truly classical style. The author takes the ground that disease is something more than a mere accident in our history, or an unwarrantable experiment upon our powers of endurance; and triumphantly appeals to the evidences of a limited existence long before the appearance of the human race.

As the highest intellects have been baffled in the investigation of the causes of disease, is not the inference therefore just, that the arrangement of these laws is due to an Intelligence superior to any created individual exemption from, or susceptible to lethific agencies? Season, influences, the self-limited character of many maladies, and the different degrees of tolerance thereof, constitute certain links in the argument; while the term *vis medicatrix naturæ* is designated a very inappropriate expression for the vital principle of endurance or the development of the reserved force of the system.

Still we may guide the malady, and, while recognising the laws which govern it, not ignorantly produce results which science should teach us to prevent. False facts and non-sequitur conclusions should be avoided, and the patient taught to acquiesce in an intelligent submission to the laws of disease.

Catalogue of the Alumni Officers and Fellows of the College of Physicians and Surgeons, Medical Department of Columbia College, in the City of New York, from A. D. 1807 to A. D. 1865. New York: Baker & Godwin, Printers, 1866.

This catalogue, published by a committee of the Alumni Association, is a model of historical research and typographical elegance, in which latter particular it is perhaps unsurpassed. The post-office addresses and medical honors of the graduates are given as far as ascertained; and many dates of deaths, with the nature of the final disease, duly noted. The rather glaring error, in the case of the first woodcut, of transferring the honor justly due the Pearl street to the Barclay street edifice, is however to be regretted, and will, it is hoped, be corrected in future issues. Perhaps, also, a more general rendition of the dates of tenure of the positions held, a revision of the nomenclature of others, and the insertion of one or two omitted names, might still further conduce to the absolute accuracy of the work. According to the summary, the number of Alumni, including sixteen upon whom honorary degrees were conferred, amounts to 2147, of whom 442 are known to be deceased.

National Quarantine.—The Hon. W. J. Stillman, U. S. Consul at Canea, in a communication to the Hon. W. H. Seward, Secretary of State, dated Feb. 12, 1866, suggests a mitigation of stringent quarantine regulations by requiring that a sworn Health Officer, responsible to our authorities, should be taken on board at the vessel's point of departure; also, that in case of any outbreak of the disease, the time occupied by the voyage should be counted as part of the quarantine. By this means he thinks the temptation to conceal infectious maladies on board would be removed. He also proposes a reference of the matter on the part of our representative to the International Sanitary Commission at Constantinople, as an expedient worthy of universal adoption, and calculated to save much annoyance on the long lines of travel. From certain observations, he concludes that not less than fourteen days is required to isolate the pestilence.

The Charity Hospital.—The name of the Island Hospital has been changed to Charity Hospital.

PENNSYLVANIA HOSPITAL.

RHEUMATIC ARTHRITIS.—HOW TO DISTINGUISH IT FROM RHEUMATISM AND GOUT.—THE TREATMENT OF THE DISEASE, ETC., ETC.

SERVICE OF DR. DA COSTA.

——W——CE, a Scotchman, æt. 43, by trade a printer, states that he "took cold" in the latter part of May last from exposure, and had at that time what appears to have been a bronchitic affection. The cough still continued, when he was confined to his bed about the 14th of July, in consequence of being seized with intense muscular pains and fever, which lasted for about three weeks; he had diarrhœa also, but had no trouble about his joints. About the middle of August, and while still recovering from the febrile malady, his joints began to swell; but he can give no distinct history as to the commencement and course of these swellings. He noticed a gradually increasing stiffness of his shoulders, soon accompanied by difficulty in moving them, at first confined to the left shoulder, and then involving the right shoulder also. About the same time similar conditions became observable in the knee-joints, since which time the stiffness and swelling have been constant. There is also swelling of the feet, with marked deformities of the phalango-metatarsal articulations, particularly marked at the articulations of the great toes, which are dislocated so as to lap transversely the other toes.

Four years ago this patient had an attack similar to the present one, though of a much less severe character. During this attack, the toes assumed their present deformity, and the condition had not improved in the interval.

Three years and a half previous, or a little more than seven years ago, this man had his first attack of this affection, but the changes in his joints began during his second attack, and their condition has grown worse during his present illness.

In examining the present condition of the patient, we find that the joints of the fingers are for the most part unaffected with any recent trouble. There has been some swelling of the middle joints of the two little fingers, which, though enlarged, are not red. The third finger of the right hand had participated in the swelling; and during the present attack the middle joint of the middle finger of the right hand is becoming involved. The hands curve somewhat towards the ulnar side, especially when the fingers are flexed upon the palm. The elbow-joints are unaffected on either side. The shoulders cannot be moved without causing great pain; the attempt to move them on the part of the patient causing pain also. There is no redness of the joints, but they look swollen, and offer marked resistance to any attempt at motion, producing in the right shoulder-joint a sensation much resembling rustling, which is as yet imperceptible upon the left side. The knee-joints can be moved without any trouble, though both these joints are painful; still movement does not appear to cause any perceptible increase in the amount of pain. The right ankle is stiff and swollen, but not red. There is some pain experienced in moving it. The joints of the toes are all more or less partially luxated; the joint of the great toe much enlarged, and so much displaced that the toe crosses the smaller ones. There is impaired motion of these joints. The general condition of the patient does not, on the whole, appear very much disturbed. He is not strong, is somewhat emaciated, and his tongue is covered with a yellowish coat; but his appetite is fair, and his bowels regular.

Examination of the urine reveals no abnormal acidity, nor any evidence of the presence of albumen or of the phosphates; but there is a slightly heightened specific gravity, which is the only departure from a normal condition. The heart sounds are not very strong, but reveal nothing abnormal. The character of the pulse corresponds to that of the sounds of the heart, the pulse being feeble, and numbering 78 to the minute. The skin is rather cool. There is no fever. There are no pulmonary symptoms of disease. Resonance on percussion is good, and the patient has no cough remaining.

This is a case of rheumatic arthritis, an obscure disease, and but little understood, confounded with rheumatism and with gout, yet differing from both. For a long time—indeed ever since rheumatism has been at all studied—cases have been observed differing from ordinary rheumatism, and differing also from gout. The manner in which they differ from rheumatism is admirably illustrated in the case under consideration. They differ in attacking the smaller joints with just as much readiness as they attack the larger joints. Further, they differ from rheumatism, or at least it may be stated to be a very striking feature of the arthritic malady, that it almost invariably attacks joints symmetrically; that is to say, the corresponding joints of each side of the body; and the present case affords a marked instance of this symmetry of disease. The perfect absence of fever is another point of difference between rheumatism and rheumatic arthritis; and this same absence of fever exists in cases running what might be termed a more apparently acute course. Though there may at the onset be little heat of skin, there is nothing like the ordinary phenomena of a febrile attack of articular rheumatism. Another proof of its difference from rheumatism, as is well shown in the present case, is the entire absence of cardiac complication. Had this been a case of articular rheumatism passing through three acute attacks, it is very probable that there would have been some marked cardiac complication, the advance of which is one of the distinguishing features of the arthritic disease.

But the disorganization and structural changes in the joints which it produces are the most important of all the signs of difference. This result is exceedingly different from the effects of an ordinary attack of rheumatism. However severe the attack of rheumatism may be, the patient generally recovers, with very little change in the nature of the joints. Rheumatic arthritis almost invariably leaves behind it some traces, in a disorganization of the joints.

The points of difference between this disease and gout consist in the former being of so much longer duration; it is, comparatively speaking, a disease running a somewhat chronic, or a subacute course. From a gouty attack, the patient will recover in a week or two, while the disease we are investigating is one which lasts essentially for months, as it has done in the present instance. It also differs in not leading to "chalk stones," as gout does, which causes a deformity of the joint of a different character. Again, in gout there is an excess of uric acid in the blood, and there is no such excess here. Though from the involvement of the small joints this affection might be considered gouty, and although it approximates more closely to gout than it does to rheumatism, there are yet points of difference sufficiently distinct to discriminate between the two maladies; and although the small joints are affected, so likewise are the larger joints.

This, then, is just one of those cases belonging to that general class usually described as a mixture of the two diseases, gout and rheumatism, or an illustration of what

is called rheumatic gout. It is hardly credible that the two diseases are really blended in this way, although the case presents symptoms of both. It may rather be viewed as a distinct affection, as distinct as any diseases are that are at all kindred, but unquestionably with clinical features as distinct from rheumatism or gout, as typhus fever presents from typhoid fever.

The structural disease present consists in positive inflammation, fixing itself upon a joint; and hence the qualifying term *arthritis*, which conveys a better idea of the disease than if we call it rheumatic gout, or gouty rheumatism, though we may designate it rheumatic arthritis if we wish to cling to the idea of its rheumatic origin. It possesses, indeed, more of the elements of true inflammation of the joints than does any rheumatism. Here is inflammation taking place, with effusion into the capsules of the joints, with the result of inflammation, thickening; with dislocation of the joints from alteration of all their ligaments, without any deposit of chalky material, as in gout. Moreover, with, undoubtedly, often in time, absorption of the cartilages between the ends of the bone and friction of these denuded surfaces, producing a shining condition, which has been compared to the appearance of polished ivory or porcelain. Such a state of things never follows rheumatism. This condition occurs not alone in one joint, but in several; for the symmetry of the disease is exhibited in the chronic changes as well as in the more acute conditions of the disease.

The prognosis of this disease is exceedingly unfavorable. It is a terribly crippling malady, presenting a prognosis much worse than that from rheumatism or gout.

A policeman afflicted with this disease was under the care of Dr. DaCosta, some years ago, who had every joint in his body affected similarly to those of the foot of the patient before the class, even the articulation of the jaw having undergone disorganization, rendering the sufferer a helpless cripple, unable to move, and almost unable to swallow. He died from gradual exhaustion; this condition of things having existed for about six years, under the personal observation of the speaker. The case narrated should teach the important lesson of preventing the joints from falling into this condition, if possible. A great deal of good can be done in the early stages of this affection by keeping in view the local inflammation, and by instituting a treatment which shall be much more active locally than that pursued in an ordinary case of rheumatism. Thus, perhaps, the joints may be saved from destruction, and a state of things be prevented which it would be almost impossible to remedy. Therefore, leech the joints, blister them, apply iodine; treat them as inflamed joints, actively, during the earlier stage.

Not long ago the speaker attended a gentleman suffering with a very severe attack of acute rheumatic arthritis. The treatment recommended was instituted with the administration internally of very little medicine, and the patient recovered without the least thickening of any of the joints of the body.

As regards constitutional treatment, the ordinary alkaline treatment of rheumatism is not likely to be productive of benefit; neither will the colchicum employed in gout be more successful, whether in the acute, subacute, or chronic condition, which latter is the more generally observed character of the disease.

The treatment most likely to do good, at any stage, whether acute or chronic, is by guiacum, which has an effect, unquestionably, in many cases of rheumatic arthritis, whether given alone or in combination with iodide of potassium. The more recent the case the more likely is this treatment to prove beneficial; the more protracted, the less likely to succeed.

Under any circumstances, whether acute or chronic, this disease occurs preëminently in individuals of enfeebled constitution. Attention to the general health, therefore, assumes an importance far greater than in any other diseases of the same character. Good results may be produced by the use of cod-liver oil, arsenic, and iodide of iron, even in cases in which the disease has been of considerable standing.

The patient before us is taking half an ounce of cod-liver oil twice a day, and eight drops of Fowler's solution three times a day, and is furnished a good nourishing diet.

It may be a question of consideration whether any benefit could be expected from local treatment with such a condition of joints as the case presents. It is not too late to attempt it. Small blisters will be placed over some of these joints, and iodine will be applied locally over others, so as not to blister too many joints at once. Beneficial results often follow the local application of the plaster of iodide of lead, keeping the parts enveloped in it, even where there has been considerable structural change; but, under any circumstances, improvement comes but slowly.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

STATED MEETING, APRIL 4, 1866.

DR. JAMES ANDERSON, President, in the Chair.

DISCUSSION ON CHOLERA.

DR. A. CLARK, in accordance with a previous request of the president, exhibited a number of Cruveilhier's and Pirigoff's plates, in illustration of the pathological anatomy of cholera. These embraced representations of extraordinary congestion of the alimentary canal, enlargements of Brunner's, Peyer's, and the mesenteric glands—instances of arborescent and punctate vascularity, ecchymosis ulceration, and diphtheritic exudation; this last upon the peritoneal coat of the intestines, etc., etc. In corroboration of Dr. Hutchison's view, that the choleraic vomiting did not empty the stomach, he called attention to a plate exhibiting portions of a mushroom retained within that organ, this fungus being a favorite article of diet among the Russians during the Lenten season. In referring to the injection of saline materials into the venous circulation, he recalled an instance where 300 ounces of a solution were used, and repeated more than once, with ultimate recovery of the patient. The views of the gentlemen who had preceded him were adverse to this plan of treatment, perhaps not without reason; but in proof that the cases in which it was tested were not uniformly fatal, he quoted authority for the fact that there had been four recoveries out of twenty-six cases. As, however, chemical examination had almost settled the point that the saline materials found in the evacuations were not redundant, he, for his part, if injections were determined upon, should employ warm water alone, in order that there might be an approach to the normal constitution of the elements.

In reply to Dr. Van Kleek's question regarding the treatment recommended by Prof. George Johnson, of King's College, he would state, that as far as the views of the latter were concerned, his sources of information did not comprehend the entire field; that the therapeutical portion of the papers now in course of publication, had not as yet met his eye; but from the tenor of the reasoning that the choleraic discharges were elimi-

native or depurative, he was prepared to expect the recommendation of purgatives, castor oil at the very least.

Dr. Batchelder had been much encouraged in treating the diarrhœa ushering in the disease, by the exhibition of opium and the subacetate of lead. He thought that when the superficial capillary vessels were relaxed, a favorable issue might be reasonably expected.

Dr. Bibbins, during the epidemic of 1849, was house physician at Bellevue Hospital. At that time all cases of diarrhœa received immediate attention, and the strictest medical police was enforced. The late Dr. Gilman, then one of the visiting physicians, was much gratified with the statistics of this Hospital as compared with those of similar institutions in which the disease, according to his expressive phrase, *was treated.* The late Dr. Reese, the last resident physician of the Hospital, was strongly in favor of venesection; but the results were most unsatisfactory.

Dr. Herzog thought that in discussing the treatment, not enough stress had been laid upon the several stages or the type of the disease. Blood-letting in one epidemic had been more fatal than in another; and even the apparent recoveries might have been due to the exhaustion of the local epidemic, and not to this particular mode of treatment. As far as his experience went, he had seen saline injections into the veins employed in twelve cases—all of which had proved fatal. In the prophylactic treatment, which of course merely referred to the precursory diarrhœa, he thought that there was no appreciable difference in results in favor of either the expectant or the stimulating plan, and the same remark he would apply to the use of opium. In the expectant treatment, quietude entered, of course, as an essential element. Of the stimulants, he considered camphor the most efficient. Where rice-water stools were present, large doses of calomel had found many advocates; but ice alone, he thought, had proved quite as successful. While on this part of the subject he was reminded of a case in a German hospital, where the patient, almost asphyxiated and given over by his medical attendants, recovered by copious and frequently repeated draughts of an agent no more potent than "*lager-bier.*" A parallel case had been recently cited within their hearing by Dr. Hamilton, where the patient, at first somehow overlooked by the physicians, was at length found with a companion no other than a pail of water by his side, in which way he passed through the stage of collapse on to a complete recovery.

Dr. Vanderveer had an opportunity of witnessing, during the epidemic of 1854, the effects of blood-letting in six cases, in all of which a bounding pulse seemed to indicate this expedient. They ended fatally. In fact, he had found, upon microscopical examination, that the red blood-globules were deficient. The inhalation of chloroform gave no better results. Large doses of calomel seemed to be more beneficial in the epidemic of 1849 than in that of 1854. His usual method of employing this agent had been in doses as large as sixty grains at once, followed by thirty grains more in the event of its rejection by vomiting; and then again by a return to the original dose every hour or so, should this annoying symptom remain unconquered. The object sought for was the retention of some portion of the calomel at least.

Dr. Gunn had a hospital experience in the treatment of the disease in 1832. At his institution there had been 222 fatal cases out of 650. He had seen calomel and opium in large doses fairly tried, but with no very decided effect upon his convictions of the value of the combination. An unguent known in the hospital as the camphorated mercurial ointment next succeeded, but the medical staff finally settled down upon the following formula to be taken after each evacuation or attack of vomiting: R. Hyd. submur. pulv. opii, pulv. gum camphor, āā gr. i. Misce.

Stimulating pediluvia were also employed. He had seen the injection of a pint of tepid water into the median basilic vein during the collapse prove successful. He had likewise acted his part in the epidemics of 1849 and 1854 as a private practitioner, and had learned to rely upon the following combination: Aq. camph. ℥ iv; acid nitrici gtt. 10; and tinct. opii ʒ i. Of this, a dessert-spoonful was administered once in two hours after each attack of vomiting, or after each evacuation. With this were used red-pepper pediluvia, sinapisms to the bowels, and unslaked lime enveloped in wet muslin, placed within the axillary cavity. This last was intended to fulfil the conditions of a steam-bath whenever moisture was made to come into contact with its substance. He had seen incipient collapse changed into the wished-for warm perspiration, and the vomiting fully brought under control.

The meeting then adjourned.

EAST RIVER MEDICAL ASSOCIATION.

Regular Meeting, April 2, 1866.

Dr. Verranus Morse, Vice-President, in the Chair.

Dr. M. S. Buttles, according to announcement, read a paper upon the Pathology and Treatment of Bright's Disease. After adverting to the somewhat loose manner in which the term, in spite of the additions to our knowledge since the time of the first description by Dr. Bright in 1837 was employed, he passed to the consideration of the three distinct forms of the disease: 1. The Inflammatory (acute or chronic); 2. Waxy degeneration; and 3. Fatty degeneration

In the acute form of the inflammatory stage the urine, scanty, high-colored, and loaded with albumen, contains exudative and desquamative casts of various kinds, with epithelial cells, blood-corpuscles, salts, and other morbid products. The excessive congestion and extravasation of blood in this variety cripples the secreting function of the organ, and constitutes the principal source of danger. In the chronic inflammatory form anasarca is usually the first symptom which excites the alarm of the patient.

Waxy degeneration, the usual accompaniment of scrofulous and tuberculous disease, is characterized by dropsy, accompanied by a peculiar cachexia and a dry husky skin. As the disease progresses the urine becomes proportionately more scanty, and the casts present a peculiar waxy pale look, with a few transparent colorless epithelial cells.

The kidneys dense to the feel, and of a size greater or smaller than the normal, as the case may be, reminded him of what Dr. Watson calls dirty beeswax. The pale translucent surface due to diminished vascularity is marked; as also is the transparency of the Malpighian vessels and the tubules deprived of their epithelium. The capsule, owing to adhesions, does not peel off readily. Although Dr. Bennett suggests that this change is due to a chemical action that has taken place in the tissue, the precise nature of the degeneration is not known.

Fatty degeneration is usually associated with cardiac and bronchial difficulties. It may also accompany fatty degeneration of the heart and liver. The constant symptoms are dropsy and persistent albuminuria, accompanied with an abundance of fat globules. The fatty granules, more or less obstructing the tubules, encroach upon the surrounding secreting textures; while the com-

pressed and therefore anæmic vessels impart to the organ a dirty white or fawn color. Then, again, superficial irregularities, due to an occasional hypertrophy of the fibrous structure, may be noticed. In the treatment of Bright's disease, diuretics which stimulate the organ to undue action are to be abandoned for agents having power over the skin and bowels.

The Compound Jalap powder or Pulv. Purgans of the older Pharmacopœias, in 3 ij. doses repeated according to the exigencies of the case. Elaterium in half-grain doses repeated every hour until its effect is produced; though in appearance heroic treatment, will, unless the patient's strength is much exhausted, have a sensible effect upon the dropsical symptoms. Among the diaphoretics the vapor-bath holds the first rank; still the effects of a warm climate are not to be despised. As the disease advances, however, it seems no more than philosophical that the obstructions in the secretory tubes might be washed out by increasing the flow of the urine, whiich last might also act in a compensating way by imposing extra duty upon the pervious ones.

To bring about this result, colchicum, buchu, squills, uva ursi, digitalis, nitrate of potash, and other similar agents have been employed; but upon the bitartrate of potash Dr. Bennett chiefly bases his hopes. This may be administered in doses of from 3 ss. to 3 j. three or four times daily.

Dr. Hart had frequently noticed that when the albuminuria which accompanied pregnancy was characterized by œdema confined to the vulva and lower extremities, the issue of the case was much more satisfactory than when the hands and shoulders were the parts implicated.

Dr. Buttles was also inclined to the same view; still, as the œdema was owing to a removable cause, he had never been over-alarmed as to results unless other corroborating symptoms might warrant. He remembered an instance where, owing to the fact of the mother nursing her infant, the absence of the menses was accounted for; and the presence of albumen in the urine, together with the usual dropsical symptoms, completely deceived the medical attendants, one of whom was a gentleman of acknowledged eminence in his profession. The only doubtful element in the matter seemed what might or might not be casts under the microscope. Vaginal examination threw no light upon the case, and yet the woman was three months gone in pregnancy. Delivery accordingly effected a cure of this case of aggravated renal disease.

Dr. Hart gave his experience in the use of elaterium, and was on the whole pleased with its effect in relieving the dropsy in the class of cases indicated in Dr. Buttles's paper. When albuminuria, however, accompanied pregnancy, he prepared himself for dangers in store, although he had not always encountered them.

Dr. M. L. Smith stated that on the 12th January he was called to Mrs. S. in regard to her expected accouchement; she was thirty-three years old, five years married, had had three children, none of whom were then living. She had enjoyed good health until the commencement of the cold weather; she first noticed her face swollen in the morning; afterwards, that she could not put on her shoes on account of the swelling of her feet, and the account she gave of herself at this time was that she could not help herself. Her only stimulant was an occasional glass of ale with her husband. He found considerable œdema of face, arms, and abdominal walls; the lower extremities were enormously distended. The urine, small in quantity, upon application of heat and nitric acid, became almost solid.

A vapor-bath in bed and hydragogue cathartics were the principal features in his plan of treatment. There was no material change in her condition until the 19th January, about 11 P.M., when he was summoned in haste. Labor had then commenced. The vertex, which presented very high up, advanced slowly till about 1.30 A.M., when she was seized with convulsions; while under the influence of chloroform he delivered with the forceps a hydrocephalic child, and the convulsions not having returned within a reasonable time, he left her in a comfortable condition.

On January 25th, however, the convulsions again recurred, and the patient died before his arrival. According to the nurse's testimony, the convulsions commenced less than an hour before; although she had been slightly delirious for the preceding two or three hours. The child died two days afterwards.

The Society then adjourned.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, April 2, 1866.

Dr. Thos. C. Finnell, President, in the Chair.

The President announced that the Comitia Minora had voted to grant certificates of membership to

Prof. Austin Flint, Jr.; Drs. Wm. M. McLaury, John P. Pemberton, P. Brennan, John J. Crane, Abbott Hodgman, Chas. W. Packard, John H. Hinton, Foster Swift, Sylvester Teats, John W. S. Gouley, D B. St. John Roosa, Geo. A. Peters, William H. Draper, Edward B. Dalton; Profs. Chas. A. Budd, Alfred L. Loomis, Frank H. Hamilton, John C. Dalton, T. Gaillard Thomas, John T. Metcalfe, Wm. H. Van Buren, Alonzo Clark, Fordyce Barker.

Dr. Isaac E. Taylor read a paper on recto-vaginal and recto-labial fistula. Having described this disease in its various forms, he recommended a plan of treatment which he had found successful. After evacuating the rectum, a free and complete division should be made on the side where the fistula exists. If the lesion be double, the incisions should correspond. The subsequent treatment should be directed to procure complete repose of the parts involved. Opium should be given to prevent fæcal dejections, and no danger need be apprehended if the bowels should remain unmoved for many days. Dr. Taylor did not claim to be the originator of this plan of treatment, but gave the credit to Dr. J. Rhea Barton of Philadelphia, who published an article on this subject in 1839.

Dr. Henry M. Field reported from the Committee on Diseases. During the month of March, the weather had been favorable to the development of disease; yet there was no epidemic save a slight one of measles, and as in January and February, so in March, the deaths had been fewer than during the corresponding month of last year.

The President exhibited a section of lead pipe lined with tin to prevent lead-poisoning.

Dr. Van Kleek inquired if the dangers apprehended when Croton water was introduced, from its contamination by the lead pipes through which it flowed from the mains to the faucets, had been realized? He had not seen a case of this disease for fifteen years.

Dr. Bibbins said that for several years, while he was one of the visiting physicians of the Demilt Dispensary, during which time upwards of twenty thousand cases had come under his obversation, and since his resignation of that position as one of the attending physicians to the class of head and addomen in the same institution, he had not seen any one affected by lead disease which could be traced to the Croton water.

Dr. Downs remarked that many years since painters' colic was much more prevalent than at the present time. Persons sleeping in rooms freshly painted were seized with colicky pains. He supposed that the diminution of this disease was due to a change of materials used by the painters.

The subject was referred to a Committee of Three.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, Jan. 25, 1866.

Dr. Frank H. Hamilton, President, in the Chair.

(Concluded from page 62.)

HYPOSPADIAS.

Dr. E. Bradley exhibited to the Society an example of hypospadias in an adult aged twenty-three years, a native of Denmark. The patient presented himself to Dr. Bradley about eight months ago, at which time the penis was only an inch and a quarter in length, being firmly bound down by bands of fibrinous tissue. The organ at first, in consequence of these bands, was kept back to that extent between the two testicles as to give to the genitalia the appearances which properly belong to the female. The opening in the urethra was about an inch and a quarter from the extremity of the penis, the glans being entirely impervious. The bands were divided, and liberated the member to that extent that an inch and a quarter more was gained for it in length. During the healing of the incisions the penis was strapped up towards the abdomen. A No. 14 sound could easily be introduced into the bladder through the unnatural opening, and everything seemed to be ready for the performance of a radical operation. He had not decided between the choice of the trocar and canula on the one hand, or a plastic operation on the other. The patient had perfect control over his water, and could project a stream with considerable force; but for obvious reason he was compelled, during urination, to assume the sitting posture.

ABSCESS OF BONE.

Dr. J. C. Hutchison exhibited two buttons of bone which he had removed by operation from a gentleman who had been the subject of sinuous abscess of the humerus. He was twenty-seven years of age, a farmer by occupation, and stated, that fifteen years ago he had an inflammatory swelling of the left humerus, at the junction of its middle and upper thirds. This inflammation subsided after a while, only, however, to recur again at short intervals, for a period of three years, at the end of which time, a small piece of bone the size of the finger-nail discharged itself from the front portion of the humerus, in the situation of the insertion of the deltoid muscle. After this, the opening healed for a time, but there was constantly more or less swelling of the part. About this time, also, another opening on the inside of the humerus, just below the insertion of the latissimus dorsi, took place. This opening discharged pus in small quantities up to the time Dr. H. saw him, which was on the nineteenth of December. His health was not at all impaired by this continuance of diseased action. On examination of the limb, an eschar was discovered on the front of the arm. The humerus was somewhat increased in size, and was probably one-fourth or one-fifth larger in diameter than normal. The little sinus which was discovered on the inner side of the arm presented the usual pouting appearance. A probe passed through this upwards, entered a cavity in the bone. The suspicion was that the patient was suffering from that form of abscess of the bone, so well described by Dr. Markoe in a paper on this subject, published some years ago in the New York *Journal of Medicine*. The fact, however, that this condition of things was met with in the shaft of the bone, led also to an equally strong suspicion that it was nothing but a simple case of necrosis. An incision three inches long was made on the inner side of the arm, just inside of the nerves which accompany the brachial artery and vein. The median nerve was seen, but was not injured. The periosteum was considerably thickened, and when it was incised to the extent of an inch or two, the opening through which the probe passed was plainly to be seen. When the surface of the bone was found not to possess the usual granulated appearance which belongs to the involucrum, the supposition was stronger than ever that the disease was really abscess of the bone. On applying the trephine of a one-fourth inch diameter, just below the opening, a button of bone was removed down to the medullary cavity, there being discharged about the same time a small quantity of pus, healthy in character. The point of the trephine was then applied directly over the opening in the bone, when the cavity of an abscess was exposed to view, showing its bottom lined by delicate granulations, and a second piece removed. After the completion of the operation, a piece of lint was introduced into the wound, and the parts left to fill up. The patient was seen by the doctor ten days afterwards, when he was progressing favorably. The bone was in a state of eburnation.

The fistula through the bone was, as usual in such cases, very oblique in its course, and this circumstance explains the reason for the chronic nature of the disease. The pain was not severe at any time during the progress of the case.

Dr. Buck remarked that the disease seated itself more rarely in the shaft than in the spongy tissues of the bone.

Dr. Hutchison stated that he had operated on three cases in which the disease was confined to the spongy tissue, but had never before met with an instance in which the shaft was attacked.

The Society then adjourned.

Metropolitan Board of Health.—There have been appointed thirty assistants to the Sanitary Inspectors, with the title of clerks, who are to serve during April and May, at a salary of one hundred dollars per month. They are to be detailed for duty in the cities of New York, Brooklyn, Yonkers, Morrisania, and Flushing, by the Sanitary Superintendent.

Those appointed from New York city are:

Drs. John C. Acheson, S. P. Churchill, Joseph O. Farrington, R. W. Fields, N. Marston Freeman, John P. Garrish, N. Griswold, — Jackson, B. M. Keeney, James W. McLean, Archibald W. Maclay, — Martindale, Archibald F. Mudie, Charles W. Packard, Horatio Paine, Ezra R. Pulling, J. J. Purcell, Wm. F. Thoms, F. J. Randall, Louis A. Rodenstein, Lazarus Stern, Thomas B. Stirling, John W. Warner, and Dr. Leonard Weber.

Those appointed from Brooklyn, N. Y., are:

Drs. Bretz, James Harris, J. S. Holley, A. W. Leighton, Wm. Stewart, and Dr. C. C. Waller.

The expected aid from this temporary reinforcement, which includes the names of several of our most earnest workers in the Sanitary field, together with the additional $100,000 recently inserted into the tax-levy for the especial use of the Commission during the current year, gives us still further assurance that emergencies are to be met with determination and spirit.

Progress of Medical Science.

The Rivinian Foramen in the Membrana Tympani.—*Dr Bochdalek*, Professor of Anatomy in the University of Prague, claims to have rediscovered the *Foramen Rivini* in the membrana tympani. Describing the opening as found in the first preparation which he examined, the Professor says:—"To my great astonishment I saw, by means of a magnifying glass, on the posterior portion of a small depression on the membrana tympani, and a little behind the process of the malleus, a very small canal, in which was perceived, although very indistinctly, a punctiform opening. By means of a very fine bristle I succeeded in entering a narrow groove, not more than one-third of a line long, which ran in an oblique direction from above downwards, and somewhat anteriorly into the cavity of the tympanum, so that the bristle passed immediately beneath the case of the handle of the malleus, and just as closely beneath the *chorda tympani*, and on pushing the bristle still further, it passed under the tendon of the inner muscle of the malleus, and struck on the inner wall of the cavity of the tympanum."

The foramen was also found in the opposite membrane of the same subject, as well as in sixty-three other preparations of the membrana tympani. Forty of them were from fresh subjects; the remainder had been preserved in alcohol. In two cases only, in which examinations were made, the opening was not found. In both these cases morbid changes had occurred in the drum. The Professor, therefore, concludes that the existence of this foramen is a rule in the normal membrana tympani.—*Prag. Vierte Jahrschrift, January*, 1866.

Anæsthetic Properties of the Bichloride of Carbon.—Dr. Sansom, in a paper having the above title, and read before the Obstetrical Society of London, claimed to be the first to describe this body as an anæsthetic in his book on Chloroform, published in May, 1865. It was then called tetrachloride of carbon; it has since been determined to be a bichloride, and Sir James Simpson has suggested for it the convenient term chlorocarbon. The fluid possesses many of the characteristics of chloroform; its odor, however, is more pleasant and less pungent; its density is slightly greater, and its volatility less. It takes a longer time to induce anæsthesia. On the 4th of July, 1864, the author, in conjunction with Dr. John Harley, tried the effect of the inhalation of the new anæsthetic upon a frog. The circulation in the web of the foot was observed by the microscope throughout the process. It was seen to cause a considerable amount of irregular muscular action, and a very decided contraction of the capillary arteries. A state of torpor was then induced for three-quarters of an hour, but reflex action was not wholly abolished. Experiments were made upon dogs and guinea-pigs. In these there was considerable muscular agitation at the outset. Deep anæsthesia was slowly produced, but, once induced, continued very profound until death. The post-mortem signs were, complete collapse of the lungs and distension of the right side of the heart, so that the organ assumed a globular form. The sensations produced by the inhalation of the bichloride of carbon are at first very agreeable: there is a pleasant sensation of warmth, and, as the author thought, a freedom from the vertigo, such as is produced by chloroform. Dr. Sansom has employed it in cases of midwifery. It was readily inhaled: it mitigated the pains, and in one case almost completely abolished them; it did not interfere with consciousness. In reviewing the relative merits of the two anæsthetics, the author considered (1) that chlorocarbon has the advantage over chloroform in its being inhaled with greater comfort; it is not susceptible of decomposition with the formation of deleterious chlorine compounds; and its cost will probably be considerably less. Being much less volatile than chloroform, it will probably be best administered by pouring it upon a sponge wrung out in hot water. (2) It is, during its early stage of action, a powerful stimulant to the circulatory system. It will probably be especially valuable in midwifery, for it abolishes pain without affecting consciousness, and its tendency is certainly to increase muscular action. (3) It is not advisable to induce deep narcotism by means of this agent. Its profound effects are very persistent, and it is eliminated from the system slowly.—*Lancet, March* 17, 1866.

Poisoning by Petroleum—Clemens, of Frankfort, relates a case of a patient who had taken about two-thirds of a glass of petroleum, mistaking it for wine. He was immediately oppressed in his breathing, had palpitation of the heart and dizziness; the pulse was small, and the patient feared that he was losing his senses. He was treated with strong coffee, cold applications to the head, and fresh air; at the end of two hours he was able to go home alone.

It may be remarked that the patient had formerly, for some years, suffered at least as often as once in six months from attacks of gall-stone colic, but for a year and a half after the poisoning was not so affected.—(*Deutsche Clinik*, 1865, 1.)—*Viertel-Jahrschrift.*

Treatment of Gonorrhœal and Purulent Ophthalmia.—Mr. Ernest Hart of the St. Mary's Hospital recommends for the treatment of these affections, weak alum lotions (three grains to the ounce); the spray-douche, with the local application of the diluted nitrate of silver stick to the mucous lining of the lids.

On the Nature of Mucous Tubercles in the Region of the Vulva and Anus in Prostitutes.—In investigating the conclusions of Prof. Thiry, of Brussels—(who observed in regard to these morbid growths: 1. That they arose simply from want of cleanliness and abuse of coition, and that they demanded a purely local treatment; 2. That where ulcers do not at the same time exist, they are not virulent; and 3. That constitutional syphilis was not observed, unless there were ulcers seated on the tubercles, ending in induration)—*Dr. G. B. Soresina* made some observations which were continued for nineteen months in the Syphilitic Hospital in Milan. He watched the mucous patches occurring in the region of the genitals and anus, and treated them with simple lotions of pure water, cauterized the ulcers, and retained the patients under observation for a number of months; twenty-five cases thus observed, taught him that mucous tubercles often heal with simple lotions of water. With the exception of those cases where the disease was very extensive, the cure was complete in twenty days. Of twenty-two cases of mucous tubercles, two were only followed by secondary syphilis, although the patients were continued under observation for eighteen months. *Dr. Soresina* believes that we may conclude that mucous tubercles are not of a syphilitic nature, but a local process easily cured by cleanliness, and that it is caused by local irritation. The second proposition of Prof. T., however, cannot be maintained, since in three cases where infection experiments were made with virus from the dry mucous tubercles, they were successful;

but in two they failed. Dr. S. concludes that mucous tubercles occurring in these parts may be divided into two classes: one, and the larger one, which disappears after a purely local treatment, and is an unimportant local affection; while the other belongs to constitutional syphilis. He believes, however, that the mucous tubercles in the region of the genitals of prostitutes, while they may occur independently or in connexion with syphilis, are originally one and the same simple affection, arising from local irritation; and the nature is changed, just as a wound in a person affected with syphilis may take on the character of a syphilitic ulcer.—*Gazz. Lomb. and Prag. Viertel-Jahrschrift.*

Congenital Hypertrophy of the Tongue—Amputation.—Dr. Alfred Bolter of Ovid, N. Y. (*N. Y. Medical Journal*, Mar. 1866), relates a case of congenital hypertrophy of the tongue for which he successfully performed the operation of amputation. The patient was a girl a little over three years of age. "The tongue was protruding from the mouth to the extent of something more than an inch," and its exposed surface was blackened, dried, shrivelled, and covered with fissures, from which exuded considerable quantities of bloody serum. The organ was firm in consistence; was not unusually sensitive to the touch; and from its size the orifice of the mouth was nearly circular in shape. The patient being anæsthetized, the operation was performed by first passing a strong ligature through the body of the tongue, and drawing the organ forwards. A straight, sharp-pointed bistoury was then thrust underneath, and pushed obliquely backwards and upwards, bringing out the point of the instrument near the median line, and cutting obliquely outwards towards the canine teeth. Through the left flap thus formed a double ligature was passed laterally. The knife was again thrust through the organ, and a corresponding flap on the right side formed, leaving a central septum uncut until the vessels, two in number, were tied. This part was then severed, and the V-portion removed. The two forked extremities of the tongue were next joined together by passing the double ligatures laterally through the right flap, and tying the respective strands one above on the dorsum of the tongue, and the other underneath. The operation was finally completed by joining the two extremities of the flaps by a simple suture. The piece removed was one inch and five-eighths in length, one inch in vertical thickness, and five inches and five-eighths in circumference. The child quickly recovered, and at the end of the tenth day the ligatures were all removed, and the parts nearly healed. The lips could, at the time the report was made, be entirely closed, and the teeth nearly so. The hæmorrhage attending the operation was very inconsiderable.

Remarkable Instances of Poisoning by Carbonic Acid Gas.—The following remarkable instances of poisoning by carbonic acid gas (*British Medical Journal*) have lately been investigated in Liverpool. A fine new iron ship, Armadale, arrived at that port in September; was lying in the Huskisson Dock in charge of a shipkeeper:—"The man who was first placed in charge of the ship lived on board, and slept six weeks without sustaining the least harm in the very bunk in which three shipkeepers subsequently met their death. This man was succeeded by another, who passed his nights in the same place safely for a fortnight; but was found dead on a Friday morning. That evening another man was sent in his place, and he was found next morning lying insensible in the bunk; he was removed to the Northern Hospital, and died on the following Tuesday. A third shipkeeper, who had been sent on board on the Saturday, was found dead about three o'clock the next morning. At the inquest on the bodies of the two last victims, medical evidence was given as to the cause of death from poisoning by carbonic acid gas. The *post-mortem* appearances in both cases were similar; viz. congestion of the brain and lungs. The heart, especially the right side, was filled with fluid blood. The other organs were healthy. The age of the men was about 60 years. The circumstances which led to the accident were explained as follows by the medical witnesses who inspected the vessel. On the deck was a wooden house, well built, and almost air-tight, the doors and windows being accurately fitted. It was divided by a bulkhead into two portions, one of which contained bunks for sleeping, and the other a galley for cooking, which contained an American stove of a peculiar construction. The two compartments communicated by a doorway with a half-door, thus being virtually one room. The stove had been used for a coal fire during the entire period; and it was suggested by Dr. Trench, who had examined the ship, that the high winds which prevailed at the time, drove back into the room where the men were the carbonic and sulphurous acid gases generated by the stove."

Improvements in Instruments.

LENTE'S OINTMENT SYRINGE.

Dr. F. D. Lente, of Cold Spring, N. Y., has lately devised a simple and efficient instrument for the application of ointment to the cavity of the uterus. Although more particularly adapted to this purpose, it is capable also of a wider range of usefulness, and can be employed in all those cases in which it is necessary to apply ointments directly to parts that are deep-seated and beyond ordinary reach. It can, for instance, serve a good purpose in the treatment of deep-seated sinuses, and of ulcers in the different canals of the body.

It consists of a hollow stem made of pure silver, to allow of its being easily bent at any curve. This tube is provided with a handle which is likewise perforated in its long diameter. The handle, which is of gutta percha, is scored on one surface to indicate the situation of the concavity of the curve of the stem, as well as to allow of a firm grasp between the fingers. Into the extremity of the handle, the nozzle of an ordinary hard rubber syringe is made to fit; when the instrument is to be used the particular ointment is made of a proper consistency by heat or otherwise, and the syringe being detached, is filled with it.

The ointment is next thrown into the tube, until it completely fills it, and, if necessary, the syringe is afterwards replenished. The stem is then introduced into the cavity of the uterus or sinus, as the case may be, and by pressure upon the piston the ointment is made to ooze from the extremity of the tube, and come in contact with the surface against which it may be applied. The bulb upon the tube, which is about an inch and a half from the extremity, enables the operator to form an estimate of the distance to which the instrument is introduced. A solid stem of a flexible material accompanies the instrument, and is introduced into the tube when it is to be curved, in order to prevent any abrupt bending.

Correspondence.

MEDICAL INSTRUCTION IN PHILADELPHIA.

PHILADELPHIA, APRIL 9TH, 1866.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In my last (p. 69), mentioning the auxiliary chairs recently established in the Medical Department of the University of Philadelphia, the name of Dr. Henry Hartshorne, Professor of Hygiene, was omitted by the types. I hasten to make the correction, the more so as Professor Hartshorne is lecturing upon a very important branch too much neglected in the study of medicine; and from the talents of the lecturer, this course will probably be one of the most attractive and instructive delivered this summer. Apropos of these courses at the University, they are now in full operation, and attended by large and appreciative audiences. It must afford a great deal of gratification to all concerned, to see among the hearers a very large proportion of the Alumni of the Institution, and it is no unusual sight to see seated on those old benches so many wearers of grizzly beards and slowly silvering heads.

The special courses at the Jefferson Medical College are likewise well attended, the classes at the two institutions being about equal in numbers. The department of Clinical Surgery is under the charge of Professors Gross and Pancoast, who always attract very large classes. This Surgical clinic at the Jefferson Medical College is without doubt the largest and most instructive Surgical clinic in the country. The reputation of Professors Mütter and Pancoast in years past, and of Professors Gross and Pancoast during the past ten years, has attracted patients from all portions of the country, and a class of patients, too, that are rarely seen at any other college clinic. A great many more cases present themselves than can be operated upon before the classes, and consequently a large field is afforded for the selection of such cases as shall be most instructive to the students. The hospital beds in the College building provide temporary accommodations for patients whom it may be necessary to retain.

The department of Clinical Medicine is being administered under the charge of Dr. J. Da Costa, one of the attending physicians at the Pennsylvania Hospital, and one of the most popular as also one of the most capable clinical instructors that we have. Of course, the medical clinic of a college without extensive hospital accommodations, cannot offer an opportunity for the study of acute and protracted cases equal to the wards of a large and successful hospital; but the field for the study of chronic, walking medical cases is very large, and will be used to advantage.

There are no clinics being held at the medical department of the University, but the usual Dispensary practice is continued throughout the year. The clinics at the various hospitals are all well attended.

At the Pennsylvania Hospital, Dr. Adinell Hewson, the attending surgeon on duty, has been employing the endoscope a good deal in the diagnosis and treatment of affections of the urethra and bladder, and with satisfactory results. This instrument has as yet been but little employed in this city, and the article of Dr. Van Buren in the last number of the RECORD, accompanied as it is with explanatory illustrations, will give many of our practitioners their first insight into its character and method of employment. At the recent meeting of the College of Physicians of this city, on Wednesday evening last, Dr. John Brinton exhibited an endoscope, and had prepared a specimen; so that employing the instrument as if in use for actual surgical purposes, a pin placed transversely across the urethra, deep down, was distinctly perceived. At this College of Physicians, Dr. John A. Packard has begun the second course of the "Mütter Lectureships," his subject being "Fractures of the Upper Extremity." The resources of the Museum of the College, as well as those of the lecturer himself, will enable the course to be thoroughly illustrated.

At the Wills Ophthalmic Hospital, Dr. A. Douglas Hall, the attending surgeon on duty, is delivering a course of lectures on "Ophthalmic Medicine and Surgery," besides giving clinical instruction twice a week. A very convenient lecture-room, with dark room for ophthalmoscopic examinations, has been constructed; and although this institution is at a distance from the usual "students' quarters," the clinics are well attended. This is an excellent school for the study of ophthalmology, and the attending surgeons have acquired considerable celebrity in their specialty.

The "Nurses' Home," an institution for the instruction of suitable females for the duties of the "monthly nurse," affords, under the charge of the attending and consulting obstetricians, a great number of cases for advanced students desirous of becoming initiated into the practice of obstetrics, while there is attached to the institution a clinic for the DISEASES OF FEMALES, always well attended by sufferers and students.

There is very little of general interest going on among the profession at large. There is a good deal of talk now and then, when several physicians happen to meet together, about cholera and trichiniæ, but nothing new or startling seems as yet to have been elicited.

The determination evinced by the profession of New York to insist upon the adoption and enforcement of certain sanitary regulations calculated to protect the general health of the city, in case of the breaking out of contagion, ought to stimulate the profession here and elsewhere to similar energy.

The prospects are, that the professional interests of Philadelphia will be well represented at the coming meeting of the American Medical Association.

Yours, &c., C. J.

Obituary.

DEATH OF DR. LEMAIRE ZABRISKIE.

"AT a special meeting of the Bellevue Hospital Medical Union, held March 30, 1866, the following resolutions were unanimously adopted:

Whereas, It has pleased Almighty God to take from our midst our friend and associate, DR. LEMAIRE ZABRISKIE, through disease contracted during his residence in this hospital,

Resolved, That we sincerely deplore the loss of one whose enthusiasm and noble disposition led him to sacrifice his life in the performance of his professional duties; and that in his death the profession has lost an earnest and faithful member, and ourselves a sincere and valued friend.

Resolved, That we tender to the family of the deceased our most heartfelt sympathies in their bereavement, and that we bear witness to the many virtues which endeared him to all with whom he was brought in contact.

Resolved, That as a mark of respect, the members of this Society attend the funeral, and wear the usual badge of mourning for thirty days.

Resolved, That we transmit a copy of these resolutions to the family, and that they be published in the New York *Times* and *Medical Record*.

EDWARD FARRELL, M.D.,
W. W. JOHNSTON, M.D.,
S. AMABILE, M.D.,
Committee.

Medical News.

APPOINTMENTS.

N. Y. HOSPITAL.—Drs. William W. Hoppin and John F. Gignoux have been appointed Resident Surgeons, and W. F. Thurman, Resident Physician. Drs. Bell and Washburn are the Junior Assistants to the Surgical, and Dr. Shelding, Junior Assistant to the Medical Division.

BROOKLYN CITY HOSPITAL.—Drs. Geo. W. Grover and J. W. Clemensha have been appointed Resident Physicians to this institution.

PERSONAL.

DR. B. HOWARD, formerly of the army, and now of this city, has recently been elected a Fellow of the Royal Medical and Chirurgical Society of London. This honor was conferred upon him shortly after the presentation paper to that body, "On the Application of Sutures to Bones in recent Gunshot Fractures, with Cases; also, remarks on their similar use in some other Fractures and Operations." Dr. Howard is well known to the profession in connexion with the method of hermetically sealing penetrating wounds of the chest.

DR. EDMUND R. PEASLEE, on the occasion of his retirement from the duties of the Woman's class in the Demilt Dispensary, received a well deserved recognition of his services for the past seven years, in the shape of a complimentary preamble and resolutions, passed by the Board of Managers.

DR. HENRY DRAPER has just published an illustrated text-book on chemistry for the use of schools and colleges.

WILLS OPHTHALMIC HOSPITAL (Philadelphia).—Dr. W. W. McCLURE has been appointed Resident Physician.

DR. WM. H. THOMPSON read a paper "On the Arabic Race," before the New York Historical Society on the 3d inst., in which he gave many instances of their literary genius and extraordinary achievements as great civilizers, when Christian Europe was sunk in ignorance.

THE CHOLERA AT HALIFAX QUARANTINE.—We learn, on going to press, that the steamship *England*, Captain Grace, from Liverpool on the 28th, *via* Queenstown on the 29th ult., for New York, arrived off Halifax, Nova Scotia, April 9th, with cholera on board, and that she has been there detained in rigid quarantine. The disease appeared on Tuesday, the 3d of April, when the first case occurred. Since then there were one hundred and sixty cases to the morning of the 9th. Fifty persons died. The ship took out twelve hundred and two passengers, and had a crew of one hundred men. Three doctors went on board from Halifax, and the passengers were to be cared for, some in the hospital ship and others in shanties erected on the beach. The passengers are mostly Germans and Irish. It is thought that the disease was brought from Germany.

THE CHOLERA DISAPPEARING FROM FRANCE.—The Department of State at Washington, D.C., has received official information from the United States consuls at Brest and Cherbourg, under date of March 9. The consul at Cherbourg states that from the 10th until the end of February there occurred fifty-eight deaths from cholera, making from the beginning of the epidemic up to date, 114 days, a total of 257 deaths from cholera, in a population of 40,000. The disease seems to have disappeared, as no deaths had recently occurred, and the Sanitary Board was issuing clean bills of health. The consul at Brest reports that the epidemic has at length retired, no case of cholera having appeared since March 1. The Minister of Commerce at Paris has also ordered clean bills of health to be issued.

THE CHOLERA has broken out with great virulence on the Rhine, and may be expected to spread over Germany, Holland, Belgium, and England, during the approaching summer.

THE STATE WOMAN'S HOSPITAL.—The City Council has revoked the provision of a grant of land heretofore made to the Board of Governors of the New York State Woman's Hospital, because the institution had never entered into its possession. The boundaries of the premises were 49th and 50th streets, 4th and Lexington Avenues.

EAST RIVER MEDICAL ASSOCIATION.—At the meeting held April 2d, the following gentlemen were elected members: Dr. James H. Anderson and Dr. William Murphy. The following were elected delegates to the American Medical Association: Drs. John Hart, Truman Nichols, and Dr. Montross L. Smith. Dr. William Newman will read a paper on Meningitis at the next stated meeting.

NEW YORK ACADEMY OF MEDICINE.—At the meeting held April 4th, Drs. J. S. Crane, J. J. Hull, and J. B. Reynolds were elected Resident Fellows.

AN EPIDEMIOLOGICAL SOCIETY, upon the model of the London Association, is proposed to be incorporated in this city. The names of Drs. C. A. Budd, J. M. Carnochan, C. Henschel, C. Ramsay, and W. H. Van Buren, are connected with the movement.

Original Communications.

REMARKS ON THE THEORY OF ELIMINATION AS APPLIED TO EPIDEMIC CHOLERA.

By Austin Flint, M.D.,

PROF. PRINCIPLES AND PRACTICE OF MEDICINE, BELLEVUE HOSPITAL MEDICAL COLLEGE, N. Y.

The probability of an impending visitation of epidemic cholera invests with extraordinary importance, at the present time, all practical questions pertaining to this disease. The minds of many members of the profession are unsettled respecting the principles of treatment, and the pathological views which may be entertained must largely influence therapeutical measures, especially with those physicians who will be called upon for the first time to encounter the epidemic. Hitherto the phenomena of the disease and the fatality have been in great part attributed to the loss of the constituents of the blood which are contained in the choleraic dejections. This pathological view, of course, dictates, as a fundamental principle of treatment, an endeavor to arrest, as speedily as possible, the intestinal effusion. Measures for this object have been generally considered as the foundation of the treatment which promises most in the way of success.

Since the commencement of the present march of the epidemic a very different pathological view has been advocated, especially by Prof. George Johnson, of London. In a series of papers republished from the *British Medical Journal* in the *Philadelphia Medical News*, Prof. Johnson undertakes to establish the theory that the choleraic vomiting and dejections are eliminative; that the special poison of cholera, existing in the blood, is expelled by means of the gastro-intestinal effusion. As a necessary conclusion, if this theory be true, vomiting and purging are to be encouraged rather than restrained; the measures of treatment hitherto deemed of prime and essential importance must be hurtful, and in their place emetics and cathartics are to be substituted. Prof. Johnson does not shrink from this conclusion, but boldly reasons in behalf of the measures just named.

In the belief that the former of these views accords with existing pathological knowledge, with clinical experience, and with common sense; and believing, also, that the practice which the theory of elimination requires is likely to lead to an incalculable loss of life, the attention of the reader is solicited to some remarks suggested by the reading of Prof. Johnson's papers. The brief space which the Editor of the "Record" has assigned to me will not allow an extended discussion of the theory of elimination as applied to epidemic cholera; I can only offer a few hints with the view of giving a direction to the reflections which, at the present time, it behoves physicians to bestow upon the subject.

Prof. Johnson dwells with emphasis on the importance of avoiding erroneous theories respecting the pathology of cholera. No one certainly will differ from him in this. But inasmuch as a theory must be entertained, the important question is—What is the theory which commends itself to reason and experience? The doctrine of elimination is certainly not less theoretical than the doctrine hitherto held. It cannot be claimed that the truth of the former is demonstrated; in fact, reasonable as may be the theory of elimination in other applications, facts going to establish it upon incontrovertible ground are yet to be ascertained. Let the reader reflect upon the absence of the positive proof of elimination in the various diseases to which this doctrine is generally applied, such as rheumatism, gout, the essential fevers, etc. On the other hand, facts do certainly show that important constituents of the blood, in greater or less quantity, are contained in the choleraic effusion. There is, assuredly, more of conjecture in the theory of elimination than in the doctrine that the phenomena of the disease and its fatality are in great part attributable to the loss of blood-constituents.

Prof. Johnson places much stress upon the want of a constant relation between the symptoms of choleraic collapse and the loss of fluid by vomiting and purging. He cites the testimony of different observers, that collapse occurs in cases in which the characteristic dejections are small and even wanting. All who have seen much of cholera must have met with such cases. It is, however, an error to say that, as a rule, the choleraic phenomena and the danger from the disease are not in proportion to the quantity of intestinal effusion. In the larger proportion of cases there is an obvious relation between the loss of fluid by vomiting and purging (especially the latter) and the symptoms of collapse. This is purely a matter of clinical observation, and I appeal to those who have had large experience for the correctness of the statement just made. Admitting that this relation is not constant, how are the exceptions to the rule to be explained? *First*, the amount of liquid expelled from the stomach and bowels does not always represent the quantity of effusion. A large amount of liquid may be retained within the alimentary canal. This fact has been repeatedly observed; the loss is of course the same, whether the liquid be retained within the canal or expelled. *Second*, the amount of liquid effused does not represent fully the loss of important blood-constituents. The amount of liquid depends on the quantity of water. Now, the loss of water alone is, doubtless, highly important, but the organic and mineral substances which the effused liquid carries with it are of greater importance, and these are by no means necessarily in proportion to the quantity of water. *Third*, it is a well known truth of wide application, that the effects of identical causative morbid conditions are widely different in different cases. All persons, for example, do not bear equally well the loss of blood; a hæmorrhage which one person will tolerate well, will destroy the life of another person. It is perfectly consistent with the truth just stated, that a small amount of choleraic effusion will sometimes give rise to collapse and death, and that a large amount of effusion does not always prove serious.

Prof. Johnson argues in behalf of the theory of elimination, by contrasting the effects of hæmorrhage and of profuse suppuration with the phenomena of choleraic collapse. The analogy between the rapid effusion in cholera and the expenditure of blood-constituents in the production of pus, is too strained to require consideration. Between the serous effusion of cholera and hæmorrhage, there is an apparent resemblance; but a little consideration suffices to show that the resemblance is apparent rather than real. After hæmorrhage the blood is simply impoverished; its constitution is not so altered as to interfere materially with its circulation; the red corpuscles which remain are not incapacitated for the exercise of their functions; the conditions for animal heat are not notably affected; and the processes of nutrition, secretion, and excretion, are not arrested. On the other hand, the rapid loss of the elements which compose the effusion in cholera, occasions a widely different condition of the blood; it circulates with difficulty; the red corpuscles fail to perform their functions; the conditions for animal heat are greatly affected, and the processes of nutrition, secretion, and excretion are in a great

measure arrested. The difference between the remote effects of hæmorrhage and the phenomena of choleraic collapse is not greater than that between the immediate effects of the loss of blood and of the blood-constituents which are contained in the intestinal effusion in cholera. The argument, therefore, based on the contrast of these remote effects is of no weight.

Another argument is in like manner disposed of, viz. that based on the difference between the effects of remedies in cases of hæmorrhage and cases of cholera. The difference between the condition of the blood in cholera and after hæmorrhage sufficiently accounts for the fact that the remedies which are efficacious in preventing fatal syncope from the loss of blood may not be successful in curing patients in choleraic collapse.

Finally, Prof. Johnson contends that measures which arrest the intestinal effusion are not curative in cholera. Here is an appeal to clinical facts, and let competent observers testify with respect to these facts. That opiates and other remedies which are sometimes successful in arresting vomiting and purging, after the phenomena of collapse have occurred, do not always, or even often, effect a cure, by no means proves that it is not of vast importance to secure the successful operation of these remedies prior to the occurrence of collapse. It is undoubtedly true that the choleraic evacuations sometimes cease spontaneously in the stage of collapse, and the patient dies. I have met with examples. Moreover, it must be admitted that opiates and other remedies given in large doses after collapse has taken place may do harm. The blood-lesions existing in the condition of collapse, unhappily render recovery impossible in a large majority of cases. But measures which succeed in promptly arresting vomiting and purging (especially the latter) after the diagnostic character of cholera is fully manifested, and before collapse has occurred, do effect a cure in a certain proportion of cases. This statement is remarkable if the efficacy of treatment can ever be deduced from clinical facts; that is, if it be ever logical to infer a *propter hoc* from a *post hoc*. As this is a point to be settled by reference to experience, it is to be hoped that the profession may have the testimony of those who have had abundant opportunities of observation.

The importance of the bearings of the theory of elimination on the treatment of cholera, cannot be too much considered. If this theory be accepted, it is never desirable to interfere with the vomiting and purging; but, on the contrary, both are to be encouraged. To think of this practical result of the theory must cause a shudder to one who holds to the doctrine that the great source of danger in cholera is the loss of the blood-constituents contained in the choleraic effusion. It is to be feared that the influence of the able papers by Prof. Johnson on the minds of practitioners will lead to the loss of not a few lives.

Another practical result legitimately follows the acceptance of the theory of elimination, viz. the premonitory diarrhœa is not to be arrested. We need not go beyond the consideration of this result to disprove the theory. Certainly there is no fact in practical medicine better established than that cholera is prevented by arresting the diarrhœa which so often precedes the development of the disease. Let this fact have its due weight in the reflections of physicians on the theory of elimination. The impossibility of reconciling this fact with the theory, renders the latter untenable.

Oxygen.—It has been stated by Prof. Faraday, that the total quantity of oxygen daily required for the whole world is 7,142,857 tons.—*Scientific American.*

PAPERS UPON VENEREAL DISEASES.

By F. J. BUMSTEAD, M.D.

No. II.

The Two Diseases now Recognised in the "Syphilis" of Fifteen Years ago (1851). *Their Names.*

In a preceding paper we endeavored to place the present recognition of two diseases in the so-called "syphilis" of a few years ago upon its proper basis, viz. the perpetuity in successive generations of a local character upon the one hand, and of a general or constitutional character upon the other. We also attempted to show that proof of this kind, viz. *constant difference in the fruit or adult forms*, was always recognised by naturalists as indicative of generic and specific differences in the various departments of Natural History. In this light, it appeared that the objections frequently adduced against the more recent ideas of venereal pathology, founded upon the inability of the observer to distinguish the two diseases in question in their young and immature forms, are narrow-minded and valueless. Several instances of such false reasoning were given, One or two additional ones of recent occurrence, in which the same is implied if not expressed, may not be out of place.

In a very kind review appearing in the (London) *Lancet* of February 24th, 1866, it is said: "Dr. Bumstead applies the word chancre to what has been hitherto known as the hard sore. This is all very well and nicely squared; but we unfortunately find, in practice, that sores which look very much like chancroids, are (though exceptionally) followed by secondary symptoms; and hard chancres have been known to leave the organism uncontaminated. Mathematical precision is very desirable when it can be obtained without offending truth." To which I would add that "Mathematical precision" *in the initial lesion* is not claimed, and has nothing to do with the question of a unity or plurality of poisons.

Again, to come nearer home, at a recent examination for the house staff of one of our prominent hospitals, the following question was put by one of the examining surgeons, who (unless he designed to give a "catch-question") was as much adrift as the candidate was in his answer.

The question was this: "Is a soft chancre ever followed by general syphilis?"

Candidate (who had been "posting" on venereal) boldly answers, "No, sir;" and is very much chagrined at the reply; "Well, sir, you will find yourself very often mistaken in practice, if you believe that."

Granted the principle that as in the vegetable kingdom, so in venereal diseases, "every tree is known by his own fruit," we might now properly consider the effect of grafting one species upon another, and see what hybrids may thus arise. This point, however, will better come up hereafter. For the present, without being able to claim any blood-relationship with either of the two diseases considered—and for this we trust we are sufficiently grateful—we desire, if we may be allowed to act as sponsor on the occasion, to have a word to say about their names.

There is much "in a name," Juliet's well known interrogatory implying the opposite, "to the contrary notwithstanding." For instance, as regards our present subject, the want of a due appreciation of the character of the proof upon which these two diseases are recognised as distinct, led to the adoption of erroneous or defective names, which in their turn have done much to perpetuate the old errors. The writer of the present

article cannot claim to have been exempt from this fault in his earlier writings on venereal.

Before Bassereau's time, the initial lesions of the two diseases had the common name of "chancre;" but a qualifying adjective was generally prefixed, and we talked and read of the "soft," "hard," "indurated," etc., "chancre." After Bassereau's work appeared, the same nomenclature was for a time retained with some slight modification. The sore in the one case was a "simple chancre;" the sore in the other an "infecting chancre." Thus the truth of the totally distinct nature of the two diseases was but partially recognised, and the error was committed of supposing that the so-called "infecting chancre" was the *cause*, and not, as is the fact, the *result* of infection. We also heard discussions upon the "unity or duality of syphilis," "the unity or duality of the chancrous virus," etc., etc.,—expressions the only tendency of which could be to conceal the truth and mislead the hearer.

To the credit of Bassereau, however, be it said, that these terms and expressions did not originate with him, but with his followers. He alone at that time, it appears, comprehended to the full extent his own discovery, which he expressed in terse and simple language, without any attempt whatever to come before the world as an innovator, or otherwise than a student of science. Take for instance the proposition in which he sums up the results of his investigations, and which reads as follows:

"*Whenever a person has a chancre, and afterwards general syphilis, the generalization of the disease is first of all due to the fact that the person from whom the contagion came had a chancre which was necessarily followed by general symptoms.*"

I confess to no little admiration of this man, in common with all those who first studied his work with no better light than was previously afforded by the literature of venereal diseases, prior to 1852. The monogram which he wrote is modestly entitled, "*Traité des Affections de la Peau Symptomatiques de la Syphilis, par P. I. A. Léon Bassereau, Docteur en Médécine de la Faculté de Paris,*" etc. One might read this title upon the shelves of a bookseller a dozen times, and think a treatise on "Skin Diseases Symptomatic of Syphilis," too dry to be worth purchasing. But this same treatise upon so dry a subject is, in accurate investigation and scientific deduction, a model for imitation; and, transcending its title, it affords the basis of Venereal Pathology, as at present generally recognised. What has become of Bassereau personally since the publication of his work I do not know, and I should be grateful to any of our American students in Paris to inform us. I am not aware that he has since appeared in print, but his name will always be known as the founder of the school of Venereal Pathology, commencing, or rather revived, in 1852.

"*Mais, revenir à nos moutons,*" as Bassereau himself would express it, we have other plans of nomenclature to consider. About two years after Bassereau came Clerc, another Parisian pupil of Ricord, who, strange to say, has had with many the credit of Bassereau's discovery. Clerc regarded the two diseases referred to as merely different phases of one and the same affection, and thought he had discovered the key to these supposed modifications of the big pox in the variola and varioloid of the small pox. Clerc's idea was, that if a person already under the influence of the syphilitic virus chanced to be inoculated again, the result would be a local sore; and that the virus would be so modified that it would, in succeeding generations, when transmitted from one individual to another, go on producing a local and not a constitutional disease. To this local sore he gave the name of "chancroid," following the analogy of the term "varioloid," which we know to be variola, modified by the partial protection of vaccination or a previous attack of small-pox.

Now Clerc was both unfortunate in his analogy and at fault in his facts. Thus, regarding the former, he assumed that varioloid, if communicated to an unprotected person, would necessarily perpetuate itself in its modified form, which is not the case. And, as regards the latter, a number of instances were soon collected by various observers, showing that the syphilitic virus, when derived from a second inoculation upon a person already partially protected, and when communicated to an individual hitherto intact, would produce all the general manifestations of syphilis. We may of course, however, retain Clerc's term without adopting the theory in which it originated.

We next come to the nomenclature advanced by that eminent, but somewhat visionary Syphilographer of Lyons, M. Diday, who, from some fancied resemblance between the locale of the two diseases recently known as syphilis, and chicken-pox or varicella, calls the former *chancrella*. He still employs the word "chancroid," but applies it to the somewhat modified form of sore resulting from syphilitic inoculation of a person already partially protected from syphilis by a previous attack. Diday's terms, however, are rarely met with except in his own writings.

Finally, the German school of to-day would separate the word "chancre" entirely from syphilis, and apply it to the "local contagious ulcer of the genital organs."

These various systems of nomenclature may be thus tabulated:

The "syphilis" of fifteen years ago includes:

A constitutional disease, which now monopolizes the name of syphilis, and the initial lesion of which, except among German writers, is known as a "chancre."	A local contagious ulcer (the old "soft" or "simple" chancre," the "chancroid" of Clerc and others, the "chancrella" of Diday, the "chancre" of the modern German school).

In deciding between these names, there are several considerations which present themselves:—

In the same way that, in the early part of the present century, gonorrhœa was lopped off the "syphilis" so-called for three hundred years, so in our own time and generation, another disease, like gonorrhœa local in its character, has been amputated.

Naturally, the most prominent affection, from which the severance has been made, retains the prominent name, to wit, "syphilis." And let it be distinctly understood that, if the modern views of venereal pathology be correct, every phase of the constitutional disease referred to is syphilis, and nothing else.

Its earliest manifestation is as sure an indication of the poisoning of the system by the syphilitic virus as any of the so-called secondary or tertiary symptoms would be. We might then appropriately designate the lesion which first appears at the point of inoculation as "the initial lesion of syphilis," and it appears to me that the oftener this expression is used, and the more our ears become accustomed to it, on some accounts the better. At the same time it is a matter of convenience, and almost of necessity, that this initial lesion should have a name expressed in a single word, and not in a paraphrase; and such name can only be found in the term which has been sanctioned by long usage, and which in the minds of most medical men is intimately connected with syphilis, viz. "chancre."

It remains then only to determine what we shall call the other, to wit the local, disease originating in sexual intercourse. This disease manifests itself

only as a pustule and an ulcer. We may, to be sure, have accompanying inflammation of the neighboring lymphatics or ganglia; but this is either "virulent," in which case the virus has been taken up by the lymph-vessels and has struck root elsewhere, or else it is merely inflammatory or sympathetic, when it constitutes a complication rather than an integral part of the disease. The objections to call this ulcer "a chancre," as our German friends do, have been implied in the preceding paragraph.

Probably the association of the word with syphilis might be overcome by adopting it in this sense in our surgical text-books and special treatises upon venereal; but then, at much inconvenience, we are left without a convenient expression to denote the initial lesion of syphilis.

I can see no valid objection to Clerc's word, *chancroid*, which has already come into very general use, and which, as I judge from frequent conversations with medical men and medical students, is not liable to be misapplied. Of course Clerc's theory is valueless; but etymologically considered the word signifies "something resembling a chancre," and such the lesion in question often is. If yet the exception be taken that the word implies a connexion between two lesions which are totally distinct, the suggestion in a recent review of the writer's work in the *British and Foreign Medico-Chirurgical Review*, is a good one, viz. that we call this local sore "the contagious venereal ulcer"; the only objection thereto being, that we should thus express in several words what might better be expressed by one.

DISINFECTANTS.

By EDWARD R. SQUIBB, M.D.,

OF BROOKLYN.

The approach of summer, the general necessity for sanitary reformation, and the possibility of Epidemic Cholera, have concurred in causing an unusual number of inquiries for disinfectants, and the writer, in his connexion with the manufacture of chemicals, has had a sufficient share of such inquiries to warrant him in offering some of his views upon the subject for professional and popular consideration.

The general question is, "What is the best, cheapest, most accessible, and most easily applied disinfectant?" To this there is but one answer, since there is but one agency through which all these indications can be fulfilled, and that is simple cleanliness. All other disinfectants are but slovenly substitutes, inadequate at best, and sometimes useless. When writing of disinfectants in hospitals, Miss Nightingale says, in substance, that the mortality is more favorably affected by the simple expedients which yield cleanliness and fresh air than by any other means, and that, with careful attention to these, none other agencies are required. Now cities, and countries too, are but large hospitals, with classification and localization of diseases; with some wards less healthy than others; and with the same imperative necessity for the only effective agencies, and the same penalties for neglecting them.

If the whole community could but be impressed with the truth, that cleanliness in body, in clothing, and in diet, and cleanliness and plenty of fresh air in and about dwelling-places, are the only possible conditions of security to general health, and the only real disinfectants, there would not be the same tendency to seek for and rely upon imperfect substitutes; nor occasion for all the writing and research upon such subjects. At best, the so-called sanitary science is but a system of cleanliness, and its prime utility consists mainly in the art of applying effective knowledge of this virtue, which stands next to godliness, to the prevention and cure of general or epidemic disease. Like all other schemes of human construction, this art has its abstractions, which tend to lead it away from the simplicity of its dependence upon cleanliness; and the complicated means by which results are often, if not generally, sought for, have ingenuity, theoretical science, or some other form of advertisement, rather than practical utility to recommend them. Hence the various complex powders and liquids so much vaunted, and hence the question whether these are more effective than means far more simple and accessible. Each particular powder, liquid, and gas, undoubtedly has its special use in application to particular cases; but these cases are comparatively few, and of an individual character. None of these agents are adapted to general uses on the large scale, as affecting general health through the condition of the general atmosphere. Here the removal and prevention of filth,—that is cleanliness—alone proves disinfectant, since it is the decompositions which occur in stagnant filth that give rise to the emanations which always lower the standard of health and often produce endemic disease. When filth can neither be generally prevented nor removed, then arises the only real necessity for some means of modifying or preventing the hurtful emanations therefrom, and this is the legitimate sphere of the class of what may be called artificial disinfectants, in contradistinction from the natural disinfectant, cleanliness. But to treat the emanations independent of their source, is like treating an effect without reference to its cause, and is not rational, though often useful. When Nature, through the operation of her laws, cries "Fire!" it is not good practice to bend our energies too much upon putting the smoke out. This relation of cause and effect, and the means resorted to under this relation, divides these means, namely artificial disinfectants, into antiseptics, or disinfectants proper, which control the effect through the cause, and deodorizers, the principal though not the only effect of which is upon the emanations.

These emanations are always the results of complicated chemico-vital reactions of the nature of a fermentation, and these processes of fermentation appear to occupy that position in the great order of nature where the effects of vitality first begin to be seen to modify chemical action. In the great field of the progressive creation this appears to be the daybreak of the morning of Life. Shrouded in its dim indistinctness the primordial cell works its wonders in bending those laws which yield only to this mysterious principle of Life. Within the uncertain light of this misty domain, probably, lie the essential principles whose operation results in what we know as endemic and epidemic influences, contagion, and infection, leading to pestilence. In this initial stage of life the vital process is tender and delicate, and easily subjected to inscrutable modifications by atmospheric causes. Emanations which are sensibly the same even to the most minute scientific investigation to-day are harmless, to-morrow become pestilential, and again are modified and controlled. All that is surely and practically known of these chemico-vital reactions is that they occur in the decay of organic matters which contain nitrogen by a process of oxidation, and that the results are always detrimental to human health and life. According to the extent and character of these reactions their effect may be general in lowering the general standard of health, and rendering all departures from health difficult of management, or may have superadded to this the further effect of producing endemic or epidemic

disease of a special type. No more accurate definition of the word filth in its hurtful sense, can be given than to say it is nitrogenized organic matter in the process of putrefaction; and, as the aggregate of this filth increases or diminishes, so the aggregate of human health and life is increased or diminished, since the reactions which naturally occur in the filth, although subject to some modification and control, are yet dominant and inevitable. Only in proportion, then, as the total absence of filth in communities of mankind is a theoretical abstraction never realized, does the value of means for disinfecting that filth increase, and hence the great importance of the present inquiry in regard to disinfectants.

Masses of filth in that condition of moisture and warmth which is best adapted to produce and continue the putrefactive fermentation, have their baneful activity varied by every variation of moisture and warmth, as well as by many other agencies, and hence every such variation has an important effect upon the causation of disease, and becomes disinfectant or otherwise in proportion as it checks or accelerates the putrefaction. Increase the moisture to the extent of copious dilution with water, and the process is at once suspended, and the masses become for the time harmless. Diminish the moisture to ordinary dryness, and again the accumulations become temporarily in great measure harmless. Increase and diminution of temperature produce similar results, and if, on the one hand, carried up to about 180°, or on the other hand reduced to freezing, some of the most deleterious of the reactions are permanently arrested, and the processes must begin entirely anew.

Hence heat and cold even within the natural atmospheric limits exert very important influences; whilst artificially applied, as in steaming, boiling, baking, or freezing infected clothing or merchandise, they become, perhaps, the most powerful of all disinfectants available for such purposes. Heat, however, appears to be superior in its effects, as well as in facility of application; and although both destroy the fermentation and kill the acting generations of plants and animals, it is doubtful whether either the one or the other destroys the spores or seed from which succeeding generations may be produced.

The sensitiveness to external influences thus illustrated is a general characteristic of all the processes involved in these changes, and as a rule, all inorganic chemical compounds which are loosely held together; and all elements or compounds whose tendencies are towards further combination, interfere with or arrest these processes more or less permanently, and thus become disinfectants.

The prominent and essential characteristic of the putrefactive process is oxidation, and free access of atmospheric air is necessary to this oxidation; and yet the class of effective disinfectants comprises chemical agents of diametrically opposite action. As a rule the value of a disinfectant chemical is determined by its power either to oxidize or to deoxidize substances with which it is brought in contact, and whether it does the one or the other seems a matter of indifference as far as disinfectant results are concerned. For example, chlorine, iodine, and bromine are among the most powerful and certain disinfectants, and act as such by the avidity with which their vapors combine with the hydrogen of the watery vapor of the atmosphere to form their respective hydrides, thus setting free the oxygen of the water in the form of ozone, and becoming powerful oxidizing agents. The permanganates also owe all their properties as disinfectants to the large proportion of loosely combined oxygen they contain, and the facility with which they part with this to surrounding matters. Sulphates, as sulphate of iron, yield in the act of disinfection all their oxygen, and are reduced to sulphides, and are said not to be disinfectant at all if this separation of oxygen does not occur. On the other hand, among the most powerful of all disinfecting agencies known are the lower oxides of nitrogen and sulphur, whose tendencies are to abstract and appropriate oxygen from all sources capable of yielding it. Sulphurous acid and its salts are particularly effective, and when these have accomplished their rôle as disinfectants, they are found to have been converted into sulphuric acid and sulphates by an increase of their proportion of oxygen abstracted from the matters with which they have been in contact.

This contrariety in the essential chemical character of the most effective disinfectants cannot be explained in the present state of knowledge. It may be, however, that these delicate and sensitive processes and reactions are suspectible of being as easily arrested by over oxidation as by deoxidation, and that the presence of the resulting chemical compound may poison the pabulum against a recurrence of the same set of phenomena. It is a curious fact, having a very important bearing upon this whole subject of the causation of endemic and epidemic insalubrity, that although the admixture of powerful corrosive and deadly chemicals always destroys the existing generations of the microscopic plants and animalcula which play so important a part in these fermentations, yet such admixture seems sometimes only to have better adapted the soil and climate to another set of creatures, and the masses soon have a new order of animated nature. Whether these orders of life are alike in their tendency to insalubrity or not, or whether a particular order gives rise to particular epidemic diseases, or conditions tending to a particular type of disease, are questions of much significance and importance. The spores, or seed and ova, of all kinds and qualities of plants, animalcula, and of their connecting links, seem to exist everywhere, and each kind or order requires but its appropriate pabulum to develop it into active existence. Just as the agriculturist, by slight modifications of his soil alone, without seeding, does, at will, produce different vegetable species; or, for a still better illustration, as the Neapolitan gardener takes the scoria which has but recently been subjected to igneous fusion in Vesuvius, and by simply watering it gets from it a crop of edible mushrooms; so a set of natural phenomena, each in itself but a partial and inactive cause, finally concur in some locality, and, at some time, in their conjunction produce that condition necessary to start the train of hurtful decompositions and fermentations. Thence, from an established starting-point, the propagation is comparatively easy, and the increase is a geometrical progression until the whole pabulum of a city or of a nation may be invaded. A familiar example of this process is afforded in the making of fermented or leavened bread. It requires time, skill, and careful selection of proper materials to make the ferment or leaven afresh; or, in other words, a certain conjunction or concurrence of material, of moisture and of temperature, are absolutely requisite, as a pabulum or matrix, for developing the first generation of cells of the yeast plant from the spores which are floating about in the air, or present always in the materials. But a single generation, or even a single cell, once developed, the propagation is easy, and the increase vigorous and rapid, even in pabula not so accurately adapted to the process as the first had to be. Hence, a very small portion of this ferment or yeast incorporated with a large mass of dough, and subjected to a moderately well adjusted tempera-

ture, soon sets the whole mass into this same condition, so that a small portion of the mass mixed with another large portion of dough, communicates to it the same tendency to the same fermentation, but to no other variety of fermentation. But now, if a portion of the dough in this fermenting condition be frozen or baked, the process is not only arrested, but is destroyed, and hence baked bread, by being kept in a moist warm condition, is much more prone to undergo a new process of fermentation—namely, the acetous or putrefactive, than to take up again that particular fermentation which was destroyed by the heat in baking. Each one of these particular ferments—and the number already known is large—requires not only its particular matrix for its primary development into activity, but has the property of so exhausting or consuming its particular food in the matrix, that it becomes self-limiting in any given amount of matrix, and requires constant accessions of new material for its perpetuation; and a matrix once exhausted by a given ferment, or even partially exhausted, if the process be arrested, although left full of the spores of the first, is prone to undergo another and different fermentation, yielding a totally different set of products. That is to say, the reactions which occur in one natural order of phenomena are exhaustive, and the new conditions established by this exhaustion are thereby adapted to a new order. The soil and climate adapted to the yeasty fermentation are exhausted and impoverished by the plant, but are thus the better adapted to the starting of a new fermentation, and the sustenance of a new order of living beings. That is, the ferns and pterodactyls of a carboniferous era of these microscopic worlds have their soil and climate so modified by the natural order of changes, in which themselves play so important a part, that after a time their fossil remains only are left for the contemplation of succeeding orders and ages.

These examples and illustrations apply equally to the orders of successive creation upon the whole surface, through all the geological history of the terrestrial globe, and to those in the pile of filth at our doors. Time and space, so wonderful to us, have unknown relations to those laws which govern with the same unerring control the solar system and the microscopic cell.

(To be continued.)

A CASE OF RUPTURE OF THE BLADDER.

By CHARLES M. ALLIN, M.D.,

SURGEON TO THE NEW YORK HOSPITAL.

I REPORT this case, not because rupture or laceration of the bladder is a particularly rare occurrence, but because it presented certain peculiar features which rendered its exact diagnosis unusually difficult, and because I believe the treatment adopted—partly, it is true, with a view of perfecting the diagnosis—contributed largely to the prolongation of the patient's life, to an extent quite unusual in cases of this character.

M. H., a "longshoreman," forty years of age, an Irishman, was admitted to the New York Hospital at about two o'clock in the afternoon of January 10th, 1866. He stated that, between one and two o'clock of the day previous, while, in a playful manner, endeavoring to lift another man of about his own weight, and standing behind him, he slipped and fell backwards; the other man also falling heavily, and in a sitting position, upon the patient's abdomen. The bladder must have been distended by urine, as there had been no evacuation of the organ since early in the morning. He felt but little pain at the time; there was no faintness, and he did not suspect that any serious injury had been inflicted. A short time afterwards, however, he attempted to pass water, and finding that he could not, he walked to the office of a physician, who passed a catheter through the urethra and drew off a few ounces of bloody urine. No water had been passed afterwards, and as there had been no special desire to urinate, the physician had not been again consulted. Towards noon of the day following the fall, however, he complained of fullness about the bladder, and continued inability to pass his water, and his friends brought him to the Hospital.

When admitted, he did not appear to be suffering much pain; his pulse was but eighty, and of good strength, and his general appearance was good. There was a swelling in the lower part of the abdomen, corresponding in size and shape with that presented by an ordinary distended bladder. It was dull on percussion, was definitely circumscribed, and extended upwards about to the umbilicus, and laterally about four inches on the right, and nearly five inches on the left, side of the median line. There was no ecchymotic discoloration of the skin or recognisable œdema of the cellular tissue, and palpation revealed distinctly the presence of a fluid in the tumor. There was no extravasation, or abnormal appearance or sensitiveness, in the perineal region. With the finger passed into the rectum, though a sac containing fluid could be distinguished, there was not recognised an encroachment upon the rectal space corresponding, either in firmness or extent, with the swelling above the pubes.

Soon after his admission, about three ounces of urine, slightly bloody, were drawn away with a catheter. There was no difficulty in introducing an instrument of full size (No. 12) into the cavity from which this urine was evacuated, but, upon withdrawing it, the openings near its extremity seemed to catch in a laceration somewhere, though the exact position could not be made out. The desire to urinate was partially relieved, but there was no perceptible reduction in the size of the abdominal tumor.

The question presented was, of course, whether this distended sac containing a fluid was really the bladder, or an extravasation of urine resulting from a rupture of that organ. If it was the bladder, the urine evacuated by the catheter must have been contained in a sac outside of the bladder, and the catheter must have passed into it through a laceration of the urethra very near its vesical extremity. Were this the case, we should expect to find more evidences of extravasation in the perineum, and there would probably be no relief to the desire to urinate, after the cavity was evacuated. If the swelling was caused by extravasation of urine, from rupture of the bladder, it was singular that its form and extent should be so peculiarly defined. The location of the rupture must be somewhere in its upper portion, allowing the accumulation of the few ounces of urine which were withdrawn by the catheter, and must probably be limited to the bladder proper, the urine passing into the cellular tissue, and not into the peritoneal cavity; for, as before stated, there had been no shock or faintness, which almost always accompany such an accident.

During the first twenty-four hours after his admission, the urine was drawn off by the House Surgeon, two or three ounces at a time, at intervals of three or four hours. At the end of this time, there having been a consultation of surgeons called for another case, I asked those of my colleagues who were present to see this patient. Drs. Buck, Markoe, Parker, and Peters, examined him very carefully, and were equally divided in their opinions of the character of the tumor. We all agreed, however, in the propriety of making an explo-

ratory incision, either above the pubes, as in the high operation for stone, or through the perineum. The former plan was decided upon, and I accordingly made an incision, of about two inches in length, in the median line, and just above the symphysis pubis, down as far as the cellular tissue of the peritoneum. After passing through the skin, a clear fluid, having the smell of urine, slowly exuded from the tissues as they were divided, and, while with the finger breaking down the walls of the subperitoneal cellular tissue, there was a sudden gush of fluid, evidently urine, amounting to nearly three pints. Upon passing the finger now freely in every direction, it was found that the peritoneal cavity had not been opened, and the bladder could be felt collapsed and lying underneath the pubes. No laceration was recognised within reach of the finger, though its existence was, of course, no longer doubted. Though so large a quantity of fluid was thus evacuated, it was remarked as peculiar that the swelling did not subside but to a slight extent. The wound was left open to allow free exit to any further extravasation.

The patient recovered from the effects of the ether which had been administered, and from the operation, perfectly well, and, in a couple of hours afterwards, got up from the bed and passed some urine *through the urethra without assistance.* Subseqently, the urine was drawn repeatedly by the catheter; but, though he was directed to give notice when he desired to urinate, he persisted, when not closely watched, in passing it by the natural way.

His general condition continued very good until the 16th, when typhoid symptoms began to be manifested. During this time urine was almost constantly passing through the incision, and the abdominal swelling was rather increased, but less defined, and became œdematous in character. There was now some tenderness about the wound, and slight soreness over the abdomen, but no severe active peritonitis. His appetite and strength, however, began rapidly to fail; his tongue was dry; he became at first very restless, then delirious, then comatose, and on the 19th died, ten days after the reception of the injury.

A *post-mortem* examination was made on the following day. By extending the incision already made, it was found that the cellular tissue outside the peritoneum was in a sloughy condition, throughout the whole extent of the extravasation, which had dissected its way from the pubes to a little above the umbilicus, and far down on either side into the iliac regions. There was a laceration of the bladder, about an inch in diameter, in its left side, at about the junction of its upper and middle thirds. The edges were ragged and sloughy. The peritoneum had been pushed away, and not lacerated, but was itself now in a sloughy condition for some three inches in every direction, except downwards, around the opening of the bladder. There were, however, no evidences of general peritoneal inflammation. The bladder was considerably thickened and softened, and there was a copious diphtheritic exudation upon its whole internal surface. The position of the rupture of course afforded an explanation of the retention and evacuation by the catheter of so large a quantity of urine as has been repeatedly referred to.

A College of Dentistry.—A college of dentistry is about to be established in this city. The charter for the institution has already been granted by the Legislature, and the corporators named in the bill are as follows: Eleazer Parmly, Rev. Robert R. Booth, Dr. Wm. H. Allen, Dr. C. E. Francis, Dr. G. A. Mills, Dr. E. G. Ray, Dr. W. B. Roberts, Dr. Alexander N. Gunn, Dr. John Allen, and M. McN. Walsh.

Original Lectures.

ON CHOLERA.

By A. CLARK, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

Lecture IV. Part I.

The Theories in regard to the Origin and Spread of Cholera. (Continued.)

I now come to say a few words of each of those theories which I stated to you had been advocated more or less extensively to account for the origin and spread of cholera. First, of the ozone theory. It is not my province to teach you what ozone is. It may be "a peculiar modification of oxygen,"—"oxygen in a highly electro-negative condition." It is a something which Dr. Robinson has stated exists normally in the air in the proportion of one part to ten thousand, and which he believes is necessary to the vitalizing action of the oxygen; and yet he recognises in it a cause of acute catarrh, and in larger quantity, the power to produce inflammation of the mucous membranes and congestive bronchitis. Professor Schönbein was, I believe, the first to call public attention to the benign qualities of this agent—particularly its power to destroy the impurities resulting from organic decomposition. This is the power which has been invoked as a protection against cholera. It is claimed that its absence is concurrent with the accession and increase of the pestilence, and that its return corresponds with the decline and subsidence; while with its continued presence cholera does not occur. The laws of ozone, as stated by Dr. Robinson, which favor these opinions are, first, that it is destroyed in large towns, and rapidly destroyed in crowded, filthy, and close localities; and second, that its vitalizing effects are destroyed by great heat of weather, as well as its power to render putrefaction harmless. (It is not an *antiseptic*, for it hastens the process of decomposition, while it deodorizes its products by combining with their ammoniacal elements.) It is claimed that in certain instances cholera has subsided after a severe thunder-storm; such storms restoring the exhausted ozone. When this has occurred, the storm may have happened at a time when the epidemic had exhausted itself. I can confidently assert that in the several epidemics which have visited this city, thunder-storms have been looked to in vain for any agencies that might diminish their fatality. During the prevalence of cholera in Lexington, Ky., in 1849, Professor Peters made daily observations to ascertain the quantity of ozone in the air, and did not find that it either diminished or increased materially with the increase or disappearance of the cholera. He did not find that at the time when the cholera was most fatal, there was more or less ozone than usual. In this conflict of testimony we are not required to believe that the absence of ozone is the cause of cholera, while there seems little reason to doubt that its presence is important in neutralizing the accessory influences of decay in organic matters; and it may be, as Dr. Robinson suggests, that diseases which have a putrefactive tendency are unfavorably influenced by the negative condition of the air. I will say in passing, that ozone has been charged with being a cause of cholera. But that is one of the many hasty opinions which get little support from an extended examination of facts.*

---

* Mr. A. T. Hay (*Medical and Surgical Reporter*, March 17, 1866) expresses great confidence in the protective power of ozone. He

If we inquire for evidences that electricity, either in its positive or negative relations, is the cause of cholera, we shall find that we have no more definite information than we have in regard to the agency of ozone. It does not seem probable that we shall find in it anything that will explain the mode in which cholera is produced. In an excellent paper read by Dr. North before the Medical Association of the Eastern District of Brooklyn, lately published, a very lively account is preserved of the observations made by M. Andraud on the electrical conditions of the air in Paris during the cholera of 1849. A large electrical machine gave but the feeblest sparks up to the 8th of June, no matter what changes occurred in the weather. On that day the "sad and faithful interpreter of a great calamity," as he calls his machine, began to give larger sparks. "Towards evening a storm announced at Paris that electricity had reëntered its domain," and the next day still greater indications of its presence were given. In the six succeeding days it is claimed that the deaths from cholera fell from 667 to 355. Another observer, quoted by Dr. North, states that while cholera was prevalent in a particular town in Ireland, a large horseshoe magnet held the iron at the bottom with extraordinary force, and that the magnetic power was only diminished when the cholera abated and went to another town. Lamont at Munich could discover no fixed relations between the prevalence of cholera and the electrical conditions of the air. I do not think there is anything like uniformity to be discovered in the various electrical observations made in various countries in their relation to the disease. For the present, then, we must say that we cannot ascribe the disease either to the presence or the absence, excess or insufficiency of atmospheric electricity.

With regard to the theory that cholera depends upon a certain poison generated in the intestinal canal, and that the disease is excited by the direct contact of this material with the intestinal mucous surfaces, it should be remembered that Dr. Snow was a resident of London, where the water-supply has long been a subject of great complaint. For a part of the city it is obtained from the river Thames, the grand sewer of all the town, and at a point below the head of tide-water; so that twice a day the filth of the city flows in that direction. He may be excused for bringing grave charges against such "drinking-water," for during an epidemic it could hardly fail to be a vehicle of at least minute quantities of the evacuations. But cholera in London has not been confined to sections supplied with this water; and it is needless to say that the disease has visited towns and districts supplied with the purest water. The main question is—Are the alvine discharges poisonous when brought in contact with the alimentary mucous surfaces? Professor Thiersch could not poison mice with the fresh or recently voided matters.

Dr. Schmidt, of Munich, has recorded the fact that a drunken man swallowed half a beer-glass of the vomit of a cholera patient, slept off his intoxication, and the next day was as well as ever, and did not afterwards have the cholera. He states that there were repeated instances of the same occurrence in Germany during the epidemic of 1831 and 1832. The physicians of Munich are reported by Dr. Schmidt to have swallowed the transudations of cholera patients with impunity; Dr. Marshall states that this is an error, that the physicians *tasted* the vomited matter, but did not taste the matter discharged by stool. The chances are very few that if the rice-water dejections are poisonous, the rice-water vomit will not partake of the same quality. There is another fact. Cholera almost always ascends large rivers that serve as drains for cities. When it appeared in the eastern extremity of Europe, it ascended the Volga; when it has visited New York, it has ascended the Hudson; when it has reached New Orleans it has ascended the Mississippi and its tributaries. Now, if the cholera dejections in the water that is used for drinking were the main cause of the disease, the opposite of this should be noticed; it should begin along the upper portions of the streams and occur successively at the different towns that use the water, on its way down. It is true that few of the inhabitants on the banks of the Hudson use the water of the river for drinking, but the cities of the great west are chiefly supplied with drinking water from its rivers. These considerations, and the important fact that in hospitals those whose duty brings them into immediate relations with the discharges are not more frequently attacked than other attendants on the sick, lead us to the conviction that there is no poison in these dejections, at least when they are first voided. Dr. Thiersch states definitely that they are not poisonous at first. Professor Pettenkofer makes the same statement.

But this theory received unexpected support from the studies of Mr. Brittan and Mr. Swayne, of England. They announced that they had found special organizations in the rice-water discharges. They have figured and described them as the cholera fungi. These bodies, it is stated, are found in the drinking-water of London, and, it is presumed, will be found almost everywhere in the drinking-water of regions where cholera is prevalent. At Edinburgh, however, while the cholera was prevailing there, the microscopists of that city made diligent search, and could find none in the water. They tried to discover them in the air of the hospitals and in the immediate neighborhood of cholera patients; they condensed the moisture of the air in tubes made cold by a freezing mixture, but found nothing. They examined the dejections. Dr. Robinson and Dr. J. H. Bennett found the "annular bodies" in rice-water stools frequently, but more frequently they could not discover them; being sometimes present, and oftener absent, they were regarded as accidental, and were not, therefore, considered the cause of cholera. The same observations were made elsewhere with similar results. Dr. Parker, the microscopical pathologist of the London Hospital, states, what is very well known in regard to the inferior animals, and possibly may be true of man, that fungi of various sorts are often found in the intestinal canal, and in the dejections, but that they appear to be entirely innocent, producing no disease. In the midst of these investigations, the College of Physicians in London appointed a committee to revise the whole subject. Dr. Gull and Dr. Baly were appointed this committee. They called in the aid of skilful microscopists, and undertook their work. They were able to trace the rings or "annular bodies" to the spiral and annular tissue in cabbage, onions, and potatoes, and in the style of wheat, and in cane-sugar. (Marshall.) The "globular or oval cells," "the fully developed cholera cells," were found to exist in flour and bread, being the spores of different kinds of uredo, rust, smut or bunt of grain. (Marshall and Bush.) With regard to "the discs, with rounded edges," which were described by Brittan and Swayne as a part of the cholera fungus, this committee assert that they were not fungi of any kind, but that they were mostly soluble in ether; and it was the opinion of Mr. Bush and Mr. Marshall, that they were bran cells, and Dr. Robinson, in Edinburgh,

believes that its abundance in cold weather prevents or limits the epidemic spread of cholera in winter, and says: "During the prevalence of cholera in this country from 1849 to 1854 inclusive, I was engaged in the telegraph business, and during that whole time never knew an instance of a telegraph operator dying of, or even being attacked by cholera." This exemption he ascribes to the ozone generated by the electrical currents.

found their presence in cholera exceptional. The "large broken cells" that were regarded by Dr. Budd as cholera fungi undergoing decay, the committee referred to the different conditions of starch in the alimentary canal, of which there is always a considerable quantity. Again, with reference to the rings, it had been observed that some of them had cross-markings; these were traced to the chalk in certain medicinal preparations, like chalk mixture given in diarrhœa, and the aromatic confection. The committee repeated the experiments made at Edinburgh on the air of infected places and cholera wards; they examined the water used for house purposes in infected places, extensively; and they mildly sum up the whole by remarking that the "results were negative." So that trusting in the committee's report, this fungus theory of Messrs. Swayne and Brittan comes to naught, and I think the same must be said of Snow's theory; at least so much as claimed that the poison of cholera was a specific cell which was capable of reproduction. Yet it is but just that his opinions be admitted to a full hearing. He held that the cholera cells could be transported from one place to another in a dried state, in soiled clothes or otherwise; could be diffused in the air, carried a short distance by the wind, when shaken from such clothes, and thus make a lodgment in the nostrils or mouth, thence to find their way into the stomach and intestines. The cell element of this idea is as unimportant as it is untenable; if anything in the dried excretions can be so diffused, and can so produce cholera, the sooner it is demonstrated the better for mankind; at present it is a conjecture unsupported by adequate evidence. The opinion that cholera can be produced by filthy water is better sustained. It is asserted, for example, that "within two hundred and fifty feet of the spot where Cambridge street joins Broad street, in London, there were upwards of five hundred fatal attacks of cholera in ten days. Dr. Snow at once determined that a pump [well] in Broad street was the source of the calamity. He found that a case of cholera had originally been brought to an inn close by the pump; he came to the conclusion that the sewer from the inn had a connexion with the well, and that thus the water of the well was directly poisoned." Dr. Snow induced the authorities to remove the pump-handle, and the pestilence ceased to spread. It was afterwards ascertained that the water was contaminated by the sewage of the inn and of some of the adjoining houses. It is further said that "an old lady who had once resided in Broad street had retired to Hampstead. For several years, however, she had been in the habit of sending to the Broad street pump for a keg of water for drinking. She had never suffered from it before; she drank of this water after it had been impregnated with the cholera excreta, contracted cholera, and died. Her niece drank of the same and also took cholera, but recovered. These were the only cases that occurred in that district."

These statements are made on the authority of Dr. B. W. Richardson, who is so fully converted to Dr. Snow's doctrine, that he "ventures to state that if all his (Dr. Snow's) precautions were carried out, cholera would soon be an extinct disease." Such faith is almost contagious, whatever may be the fact with reference to cholera. Other facts of similar import are cited in support of Dr. Snow's theory. I do not doubt the correctness of these reports; but do they prove that cholera is produced by cholera excreta? The water of wells contaminated by privies and leaky sewers is not now for the first time found to be unhealthy. The National Hotel calamity is too well remembered to need much commentary. There it was believed that the emanations from stagnant sewers produced a fatal diarrhœa, at first acute, then chronic, which brought mourning into many of the best families of the land. Had cholera been prevailing in Washington that season, does anybody who has studied its laws doubt that such a diarrhœa would have been quickly converted into that disease? Before it can be admitted, on this showing, that the cholera evacuations are a specific poison, it must be made clear that if, in August, 1854, while cholera was epidemic in London, the Broad street well had been contaminated by ordinary privy sewerage, without choleraic evacuations, similar effects would not have followed the drinking of the water. The same may be said of the argument derived from the greater mortality, during an epidemic, in houses supplied with the filthy Thames water, compared with houses supplied with pure water. This difference is reported to be as great as seventy-one to five in ten thousand. Let us know what are the pernicious effects of water made foul with common fæcal matter in a cholera season before we admit, on such evidence, the specific poison of the cholera evacuations.

I stated to you that Prof. Thiersch had started the idea that cholera evacuations are dangerous, not as they are at first discharged, but in consequence of a fermentation that takes place in them; and that it is in this way that privies and other depositories of the discharges become dangerous to the neighborhood. The chief evidence upon which he bases his opinion is this. He fed mice on the freshly discharged stools, or with food impregnated with them, and it did the animals no harm; he fed mice on the fermented material; thirty-four partook of this food, thirty were disordered in from four to seven days, and twelve died; they had diarrhœa before death, and the appearances after death were, as he states, analogous to the appearances observed in persons who had died of cholera. He gave to mice the dejections after the supposed fermentation had ceased, and it did not harm them. Disinfectants, he says, are chiefly to be looked to to prevent this fermentation, such as chloride of lime, tar-water, and sulphuric acid. He supports his experiments and opinions, by stating that when cholera appeared in two prisons in Bavaria, great care was taken in one to disinfect the discharges, and but a single person suffered out of between five and six hundred prisoners; while in the other no pains were taken to prevent the fermentation of the discharges, and though the institution was much better situated in regard to salubrity, fifteen per centum of the three hundred and fifty died. This is the whole of the evidence in support of this opinion, so far as I am in possession of it. You may say the theory still lacks proof, as it doubtless does, but it is one of those statements that ought not to be rejected without further study; at least prudence urges that we take the precautions suggested by it, even though we do not fully believe it.*

* A friend, familiar with German medical literature, has translated for me the thirty-six propositions which embody, in his own language, the doctrines of Professor Thiersch's Treatise. I select from them the following, that his views of the cause of cholera may be more perfectly understood. The term *metabolic* is from μεταβολη, which signifies change or transformation, and applies, in these extracts, to poisonous changes in the albuminous substances of the fluids, dependent on putrefaction or decomposition, whether that process evolves an offensive odor or not:

Proposition 19. Albuminous bodies are incapable of diffusion through the air in the form of gases.

20. It is, therefore, impossible that metabolic poisons and ferments should exist in the atmosphere as gases.

21. They exist in a state of fine mechanical division.

24. All contagious principles that are susceptible of dissemination through the atmosphere in the form of dust, without losing their poisonous properties, are called volatile.

25. Cholera depends on a metabolic poison.

26. The materials in which the decomposition or metabolic poison of cholera is produced are principally derived from the mucous membrane of the intestines.

Nothing less than this can be said of the much more firmly supported theory of Professor Pettenkofer, which denies the poisonous nature of the evacuations under any circumstances when they are considered alone, but declares the poison to be the joint action of these evacuations and the soil. We cannot sustain or confute such an opinion by any amount of argument. Its truth can only be ascertained by the accumulation of individual facts, which favor or oppose it. The field already explored is large, and the facts, it is said, all tend to its support. It has been made more than respectable by the research it has stimulated. It has taken such hold of the professional mind that when the opportunity occurs, whether it be the coming summer, or many seasons hence, it will be subject to a scrutiny which will probably decide its claims to confidence. This theory, like those of Thiersch and Snow, recognises a protection in disinfectants applied to the discharges; but to be of any avail, they must be used from the very first, it is said; for if the soil is once impregnated it generates the poison without limit. But there are some unquestioned facts which this theory will hardly explain. In October, 1837, between the 8th and 28th, twenty persons were attacked with cholera in the Dreadnaught hospital, afloat off Greenwich, England, while the disease was not elsewhere prevailing in Great Britain, and twelve died. It did not extend to the shore, and did not appear on any other ship. Between the 7th of January and the 2d of February, 1838, fifty-five of the inmates of the House of Industry at Coventry died of cholera. The disease was not epidemic in England, and did not appear outside the walls of that institution (Gull and Baly). Cholera has broken out on shipboard, twenty-seven days from a healthy port, among persons who have travelled several hundred miles from an infected district, before reaching that port. The combined action of cholera evacuations and the soil is in such cases scarcely operative. [Dr. Burrall, of this city, in a valuable treatise on "Asiatic Cholera," published since these lectures were delivered, quotes Dr. Drasche as authority for the statement, that in a number of instances cholera has prevailed epidemically without regard to moisture in the soil, and even on the bare rock.] There are other facts observed regarding the diffusion of the disease, to be noticed as we advance, which are not readily explained by this theory.

Reversion of Internal Organs.—A non-commissioned officer recently died at Tournay of typhus, and at the post-mortem examination it was found that all the internal organs were reversed, the heart being on the right side, the liver on the left, etc.

Engraving on Glass.—M. Henry St. Claire Deville has recently exhibited to the Academy of Science of Paris some very fine engravings on glass, executed by means of a solution of the fluoride of calcium in hydrochloric acid.

28. The poison of cholera is capable of being dissolved in the blood.
29. It is in the intestinal evacuations that we find this substance in its stage of decomposition.
30. Generally the intestinal products are discharged before the metabolic stage has been reached; that is to say, a person sick with cholera produces no ripe contagion.
31. The maturity of the contagion may be produced outside the organism, through the progressive decomposition of the evacuated fluids.
32. A combination of external circumstances is necessary for the maturity as well as the dissemination of the contagion.
34. The ripe [principle of] contagion may be desiccated without losing its poisonous properties.
35. It may be disseminated through the atmosphere in the form of dust.
36. It may be carried from privies by the aid of the moisture of the ground to adjacent wells.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Case of Meningeal Apoplexy.

Reported by S. Amabile, M.D., Senior Assistant Physician.

John Cream, a native of Ireland, twenty-six years of age, by occupation a printer, was admitted in the service of Dr. Flint, February 3, 1866. The previous history is imperfect, as he was in a semi-comatose condition; but one of his friends stated that he was a very intemperate man, and had been lately on a debauch. On admission he presented the following symptoms: countenance pale; respiration stertorous; surface cool, especially over the extremities; eyes half closed; pupils normal; tongue thick and tremulous, but not coated; pulse slow and feeble.

A physical examination of the thoracic organs revealed nothing abnormal; the patient passed urine freely, which was found to be free from casts and albumen. It was difficult to arouse him, but when aroused, he answered questions coherently; there was no paralysis of any of his limbs. He remained in that condition until February 4, at 11 P.M., when he began to have some convulsive movements of all his limbs; these increased more and more until 5 A.M. of the next day, when he had a decided convulsion, consisting of a succession of clonic spasms. The convulsions were repeated three times, and he died in a paroxysm three hours later.

Autopsy Three Hours after Death.—On removing the calvarium, and opening the cavity of the arachnoid, an effusion of blood was found, occupying the anterior superior part of the left hemisphere, and somewhat depressing the portion of the brain beneath it. The blood was partly coagulated and partly liquid, and was evidently from a recent hæmorrhage.

On examining the dura mater, spicula of bone, some of them shapeless and others in the form of needles, were found in that membrane; others with very sharp points, and still in that membrane, were found penetrating the arachnoid.

Others and myself carefully examined the skull-cap, and no signs of injury were found in that bone or in its coverings.

Other viscera were healthy, with the exception of the kidneys, which were much congested, but otherwise normal.

Remarks by Dr. Flint.—The hæmorrhage in this case was doubtless due to the wounding of vessels by the needle-shaped ossific or calcareous formations. The diagnosis of peripheral apoplexy could hardly have been made, even with the knowledge of the previous history. Uræmia being excluded by the absence of albumen and casts in the urine, the symptoms seemed to point to the existence of subacute or chronic meningitis. The convulsions were probably due to the irritation caused by the ossific or calcareous formations.

PENNSYLVANIA HOSPITAL.

Local Loss of Muscular Power—So-called Rheumatic Paralysis.

Service of Dr. Da Costa.

This case is a very interesting one, exemplifying a peculiar condition which would ordinarily be classed under the head of rheumatism.

— McC—y, aged thirty-eight, is by occupation a fireman upon a steamboat. His duties as a fireman, coaling up, raking fires, &c., necessarily exposed the front parts of his thighs to a great heat. Becoming very warm in

this way, he would run on deck to cool himself off; or he might be called upon occasionally to assist the deck hands, which circumstance would be most likely to occur during inclement weather. The exposure to heat, with frequently alternating exposure to cold and damp, eventually resulted in a chronic stiffness in the anterior muscular portions of the thighs, which, when first noticed three years previously, could in great measure be overcome by approach to heat, the condition returning again as the warmth left the parts. At times it would be subdued almost entirely, but would be renewed again after any exposure to cold or damp air.

The case had been under treatment, at various times, for chronic rheumatism. A closer examination, after careful inquiry as to the history of the case, showed the so-called rheumatic condition to be confined to certain groups of muscles. *The man cannot cross his legs* one upon the other, and hence there is marked impairment of the power of the sartorius muscle. *He cannot bring his leg forward*, showing inability to use the quadriceps-extensor group. Every other motion of the limbs except such as call into play the muscles of the anterior portion of the thigh, can be performed readily; and the rest of the muscular system is sound, as is the patient's general health.

The patient complains that the parts feel stiff and somewhat sore—stinging; and all attempts at forcible motion produce pain. There is no pain along the course of the sciatic nerve, and no pain in the region of the articulations. The general physical condition of the patient is good; the appetite good; the urinary secretion normal in its constituents; the bowels regular in their action, and there are no general or physical signs of internal disease of any kind.

Faradization, by means of the electric current, was applied to the muscles affected to discover whether their power of motion was impaired. Of course, to reach the muscles, the conductors must be moistened, though where it is intended merely to affect the skin, dry conductors are employed. The application of the current on the right side shows no impairment of the electro-muscular sensibility, and no impairment of the electro-muscular contractibility. Passing the current separately, through each muscle of the quadriceps-extensor group of the left, and those of the right side, their electro-muscular contractility is found unimpaired also.

There is consequently no real paralysis.

The condition of the patient consists, therefore, in a local affection of the muscles on the anterior surface of the thighs, produced by alternating exposure to heat and damp, and resulting in stiffness, accompanied by slight painful sensations and want of power; but is not dependent on any absolute loss of power from cerebro-spinal or other organic cause.

The case is one of localized muscular disorder, and belongs to a group of cases included under the head of rheumatic paralysis.

The treatment will consist in the employment of sulphur baths, with the internal administration of sulphur.

Iodide of potassium and iodide of iron had been previously taken for some time; the former with some benefit; the latter with none.

PHILADELPHIA, March 7, 1866.

THE JEWS' HOSPITAL.—According to the annual report of the directors of the Jews' Hospital in New York, the number of persons admitted to the institution in 1865 was 420. Of these 327 were discharged cured, 46 died, and 33 remained on the 31st of December in the institution. Nearly all the others were improved. Outside the hospital 437 patients were treated. The expenses of the hospital for the year were $11,251.18.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

STATED MEETING, APRIL 18, 1866.

DR. JAMES ANDERSON, President, in the Chair.

THE CONTAGIOUSNESS OF CHOLERA IN RELATION TO QUARANTINE AND SANITARY REGULATIONS.

DR. WILLIAM C. ROBERTS read a well digested paper upon the Communicability and Contagiousness of Cholera. His views were substantially as follows: Cholera cannot be anything but a specific poison, which is proof against any attempt at strangulation upon the threshold of its appearance.

Safety and exemption from the ravages of this one great epidemic must be procured, if at all, by preventing its introduction into our midst.

Neither fixed nor certain in its course, and travelling at the rate of from 30 to 450 miles per diem, it has gone the circuit of this continent in several directions at the same time. For his part, he thought that the conclusion arrived at by Dr. Baly, in his report on "The Cause and Diffusion of Epidemic Cholera," to the effect that the question of contagion is still left open, is in conflict with admitted and recorded facts. He held, too, that the epithets "rare" and "occasional," when used in connexion with the word contagion, were simply absurd, since *a fact* of necessity cannot be otherwise than immutable. A multitude of facts may corroborate, but cannot *prove* any position. To effect this one well authenticated fact equalled a thousand. He would not, with Mons. Moneau de Gormes, in his report to the French Council of Health, deny the atmospheric-current doctrine, and claim that the pestilence was communicated to the world *solely* by direct or indirect contagion. This was an extreme view. He averred that it was a disease communicable from the sick to the well, atmospherically and by contagion. By a reproduction of the disease in the individual, the atmosphere was contaminated, and thus was the scourge multiplied until its intensity was spent from sheer exhaustion. For a model case of transmission by *fomites alone*, he would quote the following, on the authority of Dr. Simpson: During June, 1833, the smack Eagle, on board of which two cases of cholera had occurred during the passage, arrived at Montrose from London. A healthy sailor carried his unsoiled bedding to his home, which was altogether free of the malady. Two children, who had been seen tumbling two days before on the mattress laid out to air, were seized with rapidly fatal cholera, communicated it to their mother, and became the innocent cause of twenty-seven deaths out of a population of 700, through whom the infection was probably spread by personal intercourse.

Another case, where the chain of testimony was not quite as perfect, since inference in the relation of the particulars took the place of omitted statements, he might also cite. A woman picked up a fine feather bed, found floating in the water, and died of the infection in a few hours; and her sister, who nursed her, was also siezed, probably in consequence of personal contact. Another instance was that of a woman at Tuam, county Galway, Ireland, cited by Dr. Graves, who died after buying the clothes of another who perished of the disease in hospital. A sister who washed her died, as well as a third person who attended the latter. Stores from hospitals where cholera had been treated, and clothing contained in a trunk belonging to a person who had died of it during a voyage, had been known to introduce the scourge. Rags from places where it was pre-

vailing; letters even, and houses in which it was rife, have likewise communicated it. In fact, the laws which regulate its spread are identical with those governing other infectious diseases. Cholera has been introduced by infected ships. The brig Amelia was a case in point. She sailed from New York, when cholera prevailed, for New Orleans. Twenty-four died on the passage. She was stranded on Folly Island, S. C., and communicated the disease to one hundred and fifty persons on the island by means of her sick, their fomites, or both.

He would accept Dr. Simpson's definition of contagion as one of the best with which he had met. It was as follows: "The transmission, by *specific* poisons, of *specific* diseases from the sick to the healthy, both by direct contact and by the *more indirect* medium of air, or of other fomites, impregnated with the morbific effluvia, *generated in the bodies of those affected.*"

Dr. Graves's views were quoted after those of Dr. Simpson—the former gentleman rather stoutly opposed the position that the existence of nuisances had any bearing on the dissemination of the poison. The influences of this kind which were thus supposed to present peculiar attractions for the production or spread of the contagion had ever been in existence. Dr. Graves repudiates quarantine restrictions, as being far from effectual in preventing the introduction of cholera, and says that "we must submit to free trade in diseases," in preference to the greater ills of starvation and death in the manufacturing districts, which must grow out of the universal closure of ports. "Still," says this writer, "though the knowledge of its being infectious may not serve to guard us against its incursions, it may nevertheless *materially aid us* in diminishing the extent of its ravages." To this he would himself subscribe, but with greater emphasis. Dr. Copland, another staunch contagionist, arrays many powerful facts in support of his views: while he answers, seriatim, the arguments of the non-contagionists with no little ability.

Dr. W. Read, the City Physician of Boston, who was unequivocally of the opinion that cholera was neither infectious nor contagious, has recanted in the presence of numerous facts to the contrary, and has had the magnanimity to publicly avow it.

What would have been the consequences to this continent had quarantine restrictions not been enforced in the case of the Atalanta arriving here last October? What, also, in the case of the England at Halifax, with her freight of disease?

He was pleased to encounter a corroboration of these views in Prof. Clark's series of lectures, as published by the RECORD.

While he could not subscribe to the doctrine that specific diseases were engendered *de novo* from filth, etc., he was convinced of the absolute necessity of limiting the predisposition to the contraction, maintenance, and diffusion of disease, which violated sanitary laws engender, and which constitute so great an element in its mortality.

We cannot, should not be mere indifferent lookers-on, for in the words of the great Samuel Johnson, "where nothing is attempted, nothing will certainly be done."

A NEW ARTICLE OF LEADEN PIPE.

Dr. JOHN C. DRAPER then presented several transverse and longitudinal sections of leaden pipe lined with block tin. The union in this instance between these two metals he had found upon the application of several tests to be absolutely perfect, and the Croton Board have also expressed their entire confidence in the invention, as far as all practical purposes were concerned. Owing to the lateness of the hour he refrained from describing the details by which this union was effected by the manufacturer, but he would assure the Academy that they were eminently beautiful as well as scientific.

This arrangement possessed the advantage of cheapness over the pipes made entirely of tin, adopted in the villas of the wealthy. Then, too, a greater amount of flexibility was gained, which, in adaptability to constructive purposes, was no mean item in the economy of material.

As germane to this subject, he would cite an instance, occurring in one of the public schools, which should satisfy any mind that the use of water, in contact with lead for a sufficient period of time, was beyond a doubt deleterious. In this case it was noticed by one of the teachers, that on Monday mornings attacks of colic followed close upon the use of the water which had remained in the pipes from the dismissal of the school on the preceding Friday, up to that time. No fewer than forty pupils were attacked after a rather unusually protracted holiday. The evil was entirely arrested, however, by keeping the faucets open and allowing a perpetual current through them, during the intervals of disuse. In truth, he had quite often in his laboratory detected the presence of lead in water which had remained in the pipes undrawn, for some time. He would venture the opinion that many of the anomalous nervous troubles to which our people were subject, were due to a solution of some of these salts, even in pipes that were old.

The Academy, owing to the coming convention of the American Medical Association, then adjourned, to meet in special session on Thursday evening, April 26.

NEW YORK INSTITUTION FOR THE BLIND.—The thirtieth report of the managers of the New York Institution for the Blind to the Legislature of the State has just been published, giving the operations of the Asylum for the year 1865. Financially, the debt of the Institution on the 1st of January, 1866, was $130,868.26, of which $106,500 was secured by mortgage. The present deficiency to be made up by the Legislature is $24,368.26. From the report of the Superintendent it appears that for the year ending on the 31st of December, 1865, the following were the pupils in the Asylum:—Number at the close of 1864, 125; admitted during the year 1865, 34—159; left by graduation, &c., 35; number in the Institution December 31, 1865, 124. Of these there are sixty males and sixty-four females. The health of the pupils has been good. The following are the officers of the Board of Managers:—Augustus Schell, President; Robert S. Hone, Vice-President; T. Bailey Myers, Recording Secretary; Charles K. Tuckerman, Corresponding Secretary; Smith Clift, Treasurer. Of the Institution proper the following gentlemen constitute the officers:—William B. Wait, Superintendent; Attending Physician, James W. G. Clements, M.D.; Consulting Physician, Edward L. Beadle, M.D.; Consulting Surgeons, Abraham Du Bois, M.D., John H. Hinton, M.D.

PRECAUTIONARY SANITARY MEASURES AT FORTRESS MONROE, VA.—The military and medical authorities at Fortress Monroe, Va., are devising active measures for the improvement of the sanitary condition of the freedmen and other inhabitants of the peninsula. A quarantine guard-ship has been stationed in Hampton Roads, and a steamer furnished for the use of the health officer, Assistant Surgeon W. P. Wolverton.

THE N. Y. MEDICAL JOURNAL ASSOCIATION will remove, on the first of May, to No. 30 East 18th street.

THE MEDICAL RECORD.

A Semi-Monthly Journal of Medicine and Surgery.

GEORGE F. SHRADY, M.D., EDITOR.

New York, May 1, 1866.

OUR KNOWLEDGE OF CHOLERA.

DURING the last few months the all-absorbing topic which has interested the profession in this country and abroad has been that of Cholera. Discussions upon the nature of the disease have been held without number, and the different medical periodicals have not been by any means backward in ventilating the subject. All this has seemed to be necessary in view of the strong probability that the pestilence may again make its appearance during the coming season. Although from present indications we may have no right to assume that the disease will positively visit us, we have grounds enough for serious apprehension in this respect to warrant us in continuing our study of the disease.

If our fears are to be realized, we have certainly but little time left us for completing those preparations which will enable us to cope intelligently and successfully with the enemy. We have learned very much of the character of the disease, but there is still very much more that we have to acquaint ourselves with before we can, as a body, be considered capable of meeting the emergency in case it may arise.

It becomes us, in view of the near approach of the warm season, not only to inquire of ourselves what we now know of Cholera, but what we have to learn concerning it.

Let us first see what we have so far learned.

Notwithstanding the many conflicting opinions in reference to the mode of propagation of the disease, and the circumstances attending its development, we are at present warranted in assuming that it is communicable. As to the means which are to be taken to prevent its spread, we are pretty well agreed. The conclusions which the Bavarian Commission have arrived at, as the result of the very thorough investigation which it has made of the epidemic in 1854, must commend themselves for pretty general adoption. As regards its mode of propagation, the views advanced by Prof. Max Pettenkofer, one of the members of the afore-mentioned Commission, we must admit to be liable to the least number of objections.

Concerning the true pathology of the disease there is necessarily much mystification; and although some advance has been made in the knowledge of the abstract post-mortem appearances, we have still to confess that we are as yet far from being well informed upon the subject.

The vast array of facts which we have had presented to us in regard to the portability of the disease, invests the subject of quarantine with great interest. Although we may not be able to explain away certain circumstances connected with the spread of the disease in those localities where rigid quarantine had been enforced, we have no reason to say that those measures were useless. In the face of the well authenticated statements in regard to the utility of quarantine, any medical man would indeed take upon himself a grave responsibility in advising against its enforcement. Not only would the abandonment of quarantine be an invitation to a spread of the disease, but the moral effect upon a community would obviously be exceedingly prejudicial. As far as our present knowledge, goes, we are indeed forced to take such precautions against its extension as we would be led to in a disease that is known to be actually contagious; and we have not only to give due credit to the influence of quarantine, but we must needs keep constantly before us the beneficial effects which grow out of a strict attention to sanitary regulation.

All these points seem to be pretty well established, but our opinions are very far from being equally settled on others. We may be convinced as to the best means of preventing the spread of the malady, of the necessity of quarantine, and other matters connected therewith; but, we repeat, we are as yet in ignorance of its true pathological anatomy, and know but little of any particular system of treatment that may be generally available and effectual. It is to the consideration of these most important subjects that our more particular attention should be invited.

As far as the thorough understanding of the pathology of the disease goes, we must, for the present at least, content ourselves with working somewhat in the dark. The theories that have been advanced in regard to it have been numerous enough to afford a variety of choice to almost every one who is without one. Any possible view can at present be taken of its pathology, and a theory can be found to match it. We may be approaching very near the truth, but are still evidently far enough from it to stimulate renewed investigation and more extended research.

As to the treatment, there has not been enough said of the relative merit of the immense number of remedies that have already been used. The experience which has been obtained in the treatment of Cholera has been very extensive, and there are many facts connected with it of much value which are still to be

brought to light. The time has come when the profession should become possessed of these in all their detail. For this purpose free discussions upon the therapeutics of Cholera should be held before every Society, and the older practitioners who have had experience in treating former epidemics should be invited and encouraged to present their views. The results of their experience, in order to subserve the best interests, should be given in plain terms, as simple facts unbiassed by any pet theory, and not wearing the livery of any particular hobby.

We have not yet called the special attention of our readers to the merits of all the new medical journals which have made their appearance since the commencement of the year, as we preferred before so doing to make their regular acquaintance on our table. Having now had time to look them over, we take the first opportunity of presenting their claims for public recognition and patronage.

We will commence with the *Richmond Medical Journal.* This periodical is a monthly, and is under the editorial management of Drs. E. S. Gaillard and W. S. McChesney, who are also its proprietors. Each number is an octavo of eighty pages, and is devoted to original articles; foreign and domestic correspondence; a retrospect of medicine and surgery during the late war; an eclectic department; hospital and society reports; reviews and medical news; and miscellaneous articles. The first number, issued in January, gave us some idea what we might expect from Richmond; and the excellence of the succeeding numbers has been no way calculated to disappoint its friends. The editorials are written with care, and are well calculated to give a reputation to the journal for solidity and influence second to none in the country. To this journal justly belongs the credit of being the first new one issued from the South since the war; and this fact of itself, in giving evidence of the enterprise of the editors, is a good guarantee of its future success. We are glad to learn that it has been met with sufficiently liberal pecuniary support to enable it to have a publication office of its own. It has our best wishes for a brilliant career.

The Cincinnati Medical Journal commenced with the year.

We have received four numbers of this periodical, and are happy to say that it comes up to that standard of excellence which, from the character of the editorial staff, might have been anticipated. The Journal is divided up into three parts, one editor taking exclusive charge of each. The department of Anatomy, Surgery, and Ophthalmology, is edited by Professor George C. Blackman; that of Obstetrics, Diseases of Women and Children, Materia Medica and Therapeutics, by Professor Theophilus Parvin; and that of Practical Medicine, Physiology, and Chemistry, by Professor Roberts Barthalow. Each department is well worked up, and the very judicious selection of material makes the journal, as a whole, very readable and interesting. The subscription price is $2 per annum. The subscribers, of which we hope there are a great number, have reason to congratulate themselves for getting so much at such small expense.

The Medical Reporter—a new semi-monthly journal of medicine and surgery—is published in St. Louis. The editors are Drs. J. S. B. Alleyne and O. F. Potter. The first number was issued the 1st of March. It has twenty-four nicely printed octavo pages, and contains original papers, editorials, medical intelligence, and extracts. It is well managed, and is a credit to the industry and intelligence of the editors. The subscription price is $3 per annum, in advance.

The Detroit Review of Medicine and Pharmacy is another candidate for favor, and judging from the appearance of its first number, issued April 1, its promise for success is exceedingly good. The following gentlemen compose the editorial staff: Geo. G. Andrews, M. D., Samuel P. Duffield, Ph. D., and Edward W. Jenks, M.D. It is a monthly octavo, of forty-eight pages, and contains original communications, reports of societies, selections, a review of the progress of the medical societies, together with a pharmaceutical department. It is well printed, the articles are good, and the selections varied and interesting. Dr. H. Kiefer has described a fatal case of Trichinous disease occurring in Detroit, and his article is embellished with a lithographic representation of the trichina. His promise to work up the literature of the subject in the succeeding number, will, when fulfilled, doubtless furnish an interesting article for its readers. The subscription is $3 per annum.

The Medical and Surgical Monthly, of Memphis, Tenn., made its first appearance March 1. Drs. Frank A. Ramsey, D. D. Saunders, E. Miles Willett, and Wm. H. White, are the editors. It contains 67 pages of reading matter, which is divided up into original articles, editorials, and an excellent synopsis from Braithwaite's Retrospect. The first article, on the Natural and Medicinal History of Sponge, is furnished by Dr. A. K. Gardner, of New York, and is well written and interesting. The same remark applies to the articles by Drs. Pope, Saunders, Willett, and White. The subscription is $5 per annum.

Texas represents itself with the Galveston Medical Journal, which is under the editorship of Dr. Greensville Dowell. This journal is also a monthly, and each number contains 48 pages, the subscription price being $5. In the salutatory the editor remarks that this is the first medical journal published in that State, and that he intends to do his best in making it acceptable to his readers by presenting them with strictly original articles, together with the usual variety of other matter. We have seen two numbers thus far, and recommend it as deserving of the liberal patronage of the physicians of the State. They should encourage this pioneer publication, not only by contributions to

its pages, but by that more substantial aid which publishers so well appreciate.

The Atlanta Medical and Surgical Journal, edited by Professors J. G. & W. F. Westmoreland, and the Savannah Journal of Medicine, edited by Professors Juriah Harris, J. B. Read, and Dr. J. G. Thomas, are not, strictly speaking, new periodicals. They both commence a new series, after an intermission of four years, the former giving us the first number of its seventh volume, with the 1st of March, and the latter the first number of volume five, with January. Both are creditably got up, and we wish them a renewal of that success which has heretofore been so well deserved by them.

These are all the new journa's which we have thus far received; if there are any more we should like to see them, and give them a welcome to our table.

Reviews.

Asiatic Cholera, by W. F. Burrall, M.D. 155 pp. 12mo. New York: Wm. Wood & Co., 61 Walker street, 1866.

A pestilence that has, during a half century, swept into the grave more than *forty millions* of the human family, justly demands of the hygienist and the physician unceasing study and the most philosophical methods of research. Dr. Burrall has manifestly entertained this view of a professional duty which he has undertaken. His task has been well accomplished.

Opening with a well stated review of the merely historical facts relating to epidemic cholera, the author passes at once to the chief ætiological questions that concern the medical inquirer, and handles with logical skill such facts and deductions as the best medical authorities have furnished. Starting with the bare theory of contagion, the evidence and the possibilities relating thereto are candidly stated as follows:—

"The evidence in favor of the contagious nature of cholera is mostly, if not altogether, of a circumstantial character. While the disease is not contagious in the same manner as small-pox and scarlatina, yet the well authenticated cases are so numerous, in which a direct connexion has been traced between the origin of a cholera epidemic, and the arrival of an individual from an infected to a previously healthy neighborhood, that there should be no doubt as to the spread of the disease by human intercourse. This point may be considered as so well established that a practical disregard of it involves the assumption of a grave responsibility.

"The evidence which is advanced against the contagiousness of cholera does not weaken the accumulated force of the facts in its favor, some of which do not admit of a reasonable doubt; but it only shows that the liability to contagion is diminished, or strengthened, by certain localizing causes.

"Preconceived opinions, although honestly taken, have been in many instances an obstacle to the belief in the communicability of cholera from individual to individual, and the same result has been produced in others from a failure to appreciate the indirect manner in which the disease is believed, on good evidence, to be communicated."

Meteorological phenomena are duly discussed, and the phenomenal records of epidemics are adduced. An instructive sketch of the present great epidemic, with well drawn comparisons of all the visitations of cholera upon our continent, bring the reader to important logical conclusions, of which the following are of chief moment to us:

"In proportion as further study reveals more of the essential nature of cholera, unexplained phenomena will become clearer, and apparent discrepancies reconciled. Something has been already accomplished in this direction, and the following important propositions, which are sustained by sufficient evidence to justify a belief in them, are the results of comparatively recent investigations:

"*First.* Cholera is a disease which is diffused by human intercourse.

"*Second.* The cholera dejections are the chief (if not exclusive) agents in disseminating the infectious material.

"*Third.* Certain circumstances, among which moisture in the soil has a prominent, but not exclusive, part, favor the spread of the disease."

Certainly it were fortunate for human welfare if the *second* of these conclusions were *positively* the *only* conclusion to which our ætiological inquiries naturally or necessarily bring us. But, are not the facts concerning the infectious power or agency of the "rice-water" discharges susceptible of two interpretations—widely different, yet entirely harmonious—as relates to the introduction and diffusion of epidemic cholera? 1st. May we not conclude, as our author seems to have concluded, that the cholera stools or ejected fluids of the sick are more directly concerned in spreading the malady than any other agency within immediate control *during an epidemic.* 2d. That in the absence of any well recognised general epidemic of cholera in the world, or at the very close of epidemics, this supposed propagating power or agency of the "rice-water" discharges from cholera patients fails to infect either persons or localities with that *certainty* that is experienced during great epidemics; also, that while even during such *non-epidemic periods*, while it would appear that cholera may be, and actually has been, often propagated by means of the "rice-water" evacuations, the extension of such infection, so as to induce a widespread malignant epidemic, has not been known to occur.

In this manner we interpret the following testimony which Dr. Burrall has quoted from Dr. Harris, concerning the fourteen visitations of cholera to the old quarantine grounds, Staten Island.

"Concerning these repeated outbreaks of cholera at quarantine, it should be stated, that while they proved how fatally infectious the cholera poison may become in the midst of crowded hospitals and public institutions, they utterly failed to prove that from the same exclusive cause—viz. the contagion of the cholera evacuations—a world-wide epidemic could be caused. These outbreaks did prove, however, that the stools and besmeared clothing of the sick with cholera can, under certain circumstances, propagate the disease; while, on the other hand, a series of events at quarantine and in the city demonstrated, that for the production of a widespread epidemic, other important causes than the presence of the 'rice-water' stools and vomitings must be present."*

It is a special merit of Dr. Burrall's timely volume, that it so states facts as to instruct the reader most impressively and acceptably in all that relates to preventive measures and prophylaxis. We have met with no writing on cholera in our language that has more happily achieved this chief end of medical research. For this reason, no less than for the scholarly excellences of this brochure, it is sure to command the attention and regard of the profession.

The phenomena of the disease, its semeiology, pathological events, and their rational interpretation, as presented in Chapter IV., will be regarded with profound interest by the profession. The author evidently is familiar with the best and latest writers who have en-

* See Dr. Harris's Report on *Epidemic Cholera*, published by *Council of Hygiene*, Nov., 1865.

riched the pathological literature of cholera in European countries; the chapters exhibit evidences of a candid and logical study of Parkes, Budd, Johnson, Bell, Drasche, Snow, Pettenkofer; and with remarkably good judgment and scholarly taste in quotations and in abstracts, he sets forth the results of the researches and observations of foreign authorities in a graceful and logical style.

The therapeutics of cholera are discussed in Chapter V. The task is well performed; and though the author labors to find some absolute or relative values of medicines, he nevertheless concedes the inevitable conclusion which experience has taught, that in epidemic cholera Death still asserts predominant claims, except when the picket guards of prophylaxis are thrown around the patient at the earliest onset of the enemy.

An Appendix of twenty-two pages embodies, in a condensed form, a great amount of valuable and recent information upon the more important questions relating to cholera. To this Appendix we hope the publishers will urge the author to add, in the successive editions—and the editions should be numerous, if the profession does justice to itself and the publishers—the practical lessons which the progress and events of the present epidemic will teach.

All that could be wished in clearness of type, good paper, neatness of style, etc., has been done by the publishers to make this an acceptable presentation to the medical literature of the season. It is a timely publication, for which our brethren will thank both author and publishers.

Progress of Medical Science.

Arsenic in Hæmorrhoids.—Last summer a friend suffering with "hay-asthma," called upon me for a prescription. He likewise was a martyr to hæmorrhoids, and had been for years; in vain he had submitted to the ligature, to nitric acid, to incision and to excision—each of these relieved for a time, and then the trouble returned. Fowler's solution was prescribed for him, with reference solely to the asthma. At the expiration of a week, there was no improvement in the difficulty for which the arsenic was administered, but there was a remarkable change for the better in the hæmorrhoids, and a further continuance of the remedy relieved him entirely. Since that time, occasional relapses have occurred, but they yielded quite well in a few days to eight drops of Fowler's solution three times a day. It is now upwards of thirty years since Sir Charles Locock pointed out the value of arsenic in the treatment of *atonic menorrhagia;* and quite recently Dr. Handfield Jones (*Functional Nervous Disorders*) explains the result by the influence arsenic exerts in producing contraction of the blood-vessels. Doubtless this is the way too in which it acts upon the enlarged hæmorrhoidal vessels, although its application in the treatment of such diseased state is to me entirely novel, and the discovery purely accidental. That it does good I do not doubt for a moment; but that it should be resorted to, neglecting the condition of the intestinal canal with reference to proper secretion and evacuation, would only tend to discredit by failure what I believe will be proved to be a valuable application of an important remedy.—*Dr. T. Parvin, Cincinnati Journal of Medicine.*

Local Anæsthesia.—Dr. B. W. Richardson's method of producing local anæsthesia is thus referred to by the *Lancet* (March 17): "In a remarkably large proportion of the deaths following the inhalation of chloroform, slight and superficial operations only were about to be performed; a ready means of producing local insensibility to pain is therefore a highly important addition to our surgical resources. This there can, we believe, be no doubt Dr. Richardson has afforded us. He uses a modification of Bergson's handball spray producer, and employs a finely-divided spray of perfectly pure rectified ether, of 0·723 specific gravity. The skin blanches in from thirty seconds to two minutes; and by following the knife with the spray, more than merely superficial incisions may be rendered painless. Thus it will be seen that in a case where it was necessary to extirpate the eyeball, and the patient was suffering from extensive disease of the heart, so that the experienced chloroformist declined to administer that anæsthetic, the ether spray was used, with the effect of materially diminishing the terror and pain of the operation. It is a great recommendation of this process that the instrument is handy and the material accessible, although care must be taken to obtain it very pure and of the stated specific gravity. Enough has been done in the numerous and successful operations now performed under this influence—over 100 in number—to show that this method is capable of extended application; and although it may have its disadvantages—such as sometimes itself causing much local irritation and subsequent excoriation, though it fail in many cases (of extraction of molar teeth especially) and be inconvenient in others,—yet there remains a large balance of cases in which its application will evidently be of the most valuable and beneficent utility. Not only will it probably supersede ice and salt as a local anæsthetic, but it will make chloroform unnecessary in many cases, and will render painless a number of minor operations now a source of great alarm and suffering."

The Vessels on the Yellow Spot of the Retina.—On a minute injection of the retina, we find a much thicker capillary network than the ophthalmoscopic appearances would lead us to suppose. Even in the *Macula lutea*, which is generally supposed to be without vessels, we find both in the newly-born and adult subject a fine capillary network. The vessels have on this portion of the retina a course tending towards the central foramen. The most prominent are those running from above downwards, and from below upwards; those running from within outwards are smaller; and the smallest are those passing from without towards the middle of the fovea. They anastomose on the *Macula lutea* to a network, whose meshes are quite wide. * * * The foveal vessels are principally twigs from the branches of the *arteria centralis retinæ*, which run about the point of direct vision in an arched manner. When the injection is imperfect, the coloring material generally remains on the border of the macula, and the vessels seem to suddenly end there. This sudden termination shows that coloring matter has not reached the furthest branches. * * * The injections which led to the above results were made in children from the common carotid; in adults, from the ophthalmic artery. *Dr. J. Niemetschek, Viertel-Jahrschrift Prag., Jany.* 1866.

Citric Acid as an Application in Cancer.—Charles J. Denny, M.R.C.S. (*Lancet*), has recently reported a case of scirrhus of the tongue, in which the local application of citric acid was seemingly attended with benefit. The patient was a sailor, aged 70, who came to the surgeon complaining of pain along the whole side of

the face, and difficulty in mastication. On examination, cancer of the tongue was discovered to be the cause of these symptoms. As the disease had extended too much to think of removing it, there was nothing left to be done but to palliate. Large doses of anodynes were administered, with, however, but little benefit. The patient having seen an account in a paper of the good effects of citric acid in cancer, begged that a trial should be made of its efficacy in his case. A mouth-wash, containing a drachm of citric acid to eight ounces of water, was ordered. Mr. Denny thus speaks of the results of its use:—"He came to me a few days after, and said he felt greatly relieved from its use. When at all suffering he applied it, and the pain disappeared like magic. I may say here that it must be used two days before much effect can be expected. He can now sleep well and go about his business comfortably, which is that of a letter-carrier for a large works. He takes no opiates, and firmly believes, as I do, that he has found out the means of soothing the way to death."

Hypodermic Injection of Quinine.—Dr. Jas. M'Craith, senior surgeon to the Smyrna and Ardin Railroad, has sent a communication to the Royal Medical Chirurgical Society relating to the cure of malarious diseases amongst the men employed on those works, by the hypodermic injection of quinine. The article is thus referred to by the *British Medical Journal:* "The writer first explained the relative equivalent values of different terms used by French and English authors in writing of continued, malarious, and typhoid fevers; and then described his experience of the fearfully sudden effects of the malaria poison on men employed on the railroad, and the universal applicability of quinine in this fever, and indeed in all diseases which weakened the general health and strength, and which on that account were sure to take on the character of the prevailing fever epidemic, whatever it might be. He then described the various forms of malaria fever, which he arranged under three heads, as Simple Ague, Masked Fevers, and Pernicious Fevers. The hypodermic method of injection was found most valuable in the third class of cases; and an example was detailed in which a patient, who had been in a profound coma for a long time, and was incapable of swallowing anything, was rapidly relieved by the injection of three grains and a half of quinine in each arm. A form of the pernicious fever called by the French 'algide,' and remarkable for the long continuance of the 'cold stage,' out of which the patient rarely recovers, was mentioned as one in which, from the intestinal canal being very much obstructed, the injection would most probably prove successful. Several cases of the choleraic form of malaria fever and of ordinary fever were also related, which were found to yield to the subcutaneous exhibition of the specific, after the ordinary method had proved quite ineffectual. The writer described the symptoms of two forms of yellow fever, the epidemic contagious and the endemic malarious non-contagious, with some severe cases of the latter, in which neither the exhibition by the mouth nor the hypodermic injection of quinine succeeded. The epidermic acid treatment, accidentally suggested to the author a few years since by Mr. Wordsworth, was found to be very successful with the white race only; but the climate of Smyrna does not suit the black, and he must eventually die out of it. No injurious results had been found to follow the hypodermic injection, but small abscesses were not unfrequent. The author did not think the hypodermic method would supersede the usual treatment by the mouth, but that it would prove extremely useful where a great scarcity of the remedy existed, or where the symptoms would not allow its administration by the usual method."

Chronic Bronchitis in the Old.—Dr. Headlam (*Lancet*) finds the tinct. of stramonium given in doses of ten minims, combined with other expectorants, very useful in those cases of chronic bronchitis in the old, where there is great dyspnœa, accompanied by a dry state of the bronchial tubes.

Tumor resembling the Female Mamma.—Dr. Peter Pineo, late Medical Inspector U. S. A., being present at a recent meeting of the Boston Society for Medical Improvement, related the following case: In April, 1865, a negro, forty years of age, presented himself for examination as a recruit in Charleston, S. C. On being stripped, his physical condition was found to be perfect, with the exception of a round, flattish protuberance on the anterior aspect of the right thigh, at about the juncture of the upper and middle thirds. This protuberance was about four and a half inches in diameter, had a glandular feeling, and an elevation in the middle like a nipple, with a depression at its point, and resembled strongly a female mamma. The negro said it had always been there, and from his account it seemed to have been congenital. The resemblance to a female mamma was so great that the examining surgeon called the attention of Dr. Pineo to it. Dr. P. showed a drawing of the tumor.—*Boston Medical and Surgical Journal.*

Rupture of Uterus; Gastrotomy Successfully Performed.—Dr. E. Miles Willett (*Medical and Surgical Journal*, Memphis, Tenn., March, 1866) relates a case of rupture of the uterus for which gastrotomy was successfully performed. The patient, after having previously given birth to two still-born children, was seized with her third labor, March 20, 1865. It showed nothing remarkable in its progress until twelve hours after its commencement, when Dr. Frayser, the attending physician, called in Dr. Willett to assist him. They then found the patient somewhat restless and disturbed in mind. She had vomited freely, and was throwing up bile when we entered the room, but had not had a labor pain for half an hour. The blood in the vagina, the recession of the head, the absence of labor pains, and the irregular surface of the abdomen, through the walls of which could be distinctly felt an elbow, made the diagnosis of rupture of the uterus absolutely certain, although the attendants did not think that she had suffered much, and could not remember any particular agonizing pain. After consultation, the performance of gastrotomy was decided on, but the operation could not be commenced, owing to a difficulty in obtaining the consent of the friends of the patient, until two hours and a half after the rupture occurred. Assisted by Drs. Frayser and Grant, he made an incision in the median line, through the skin and cellular tissue, from below the umbilicus to within an inch of the pubes; but as this would not give sufficient room, it was extended upwards and to the left of the umbilicus. The peritoneum was then opened, and with a probe-pointed bistoury, guided by the finger as a director, the incision was completed. It was found that the child and placenta had been expelled by the uterus into the cavity of the abdomen, the child's head rested on the brim of the pelvis, and the uterus had contracted sufficiently to prevent exhausting hæmorrhage. After removing them, the blood and amniotic fluid was sponged out as well as could be done, the edges of the wound were drawn together with interrupted sutures and adhesive plaster,

the body-bandage adjusted, and cold applications ordered. During all this time the patient was fully under the influence of chloroform. The pulse was ninety-six, and sufficiently full before the operation; one hour afterwards it increased to one hundred and ten. During the night she took six drachms of elixir of opium. No untoward symptoms retarded the recovery.

Bromate of Quinine—a New Remedy.—M. Courtener, a Russian physician, recommends the bromate of quinine as a new and useful remedy applicable to intermittents and some other diseases, such as dysentery, typhoid fever, and diphtheria. It has a sedative action superior to the sulphate of quinine, and therefore may be given in smaller doses. M. Courtener considers 50 centigrammes a sufficient dose. It is quite soluble, one part being dissolved in four parts of water—a property which adapts it for hypodermic injections. The use of it is rarely followed by tinnitus aurium.

This medicine is prepared by treating quinine with hydrobromic acid and then evaporating to crystallization or dryness.

Mr. Courtener recommends it as a prophylactic of cholera and in its period of incubation.—*Bulletin Gén. Therapeutique, Feb.* 16, 1866.

Menstruation and Abortion at Seventy-two Years of age.—Dr. Priou mentions this case in the *Bulletin de la Société de Médécine d' Angers*:—The patient, seventy-two years of age, began menstruating at sixteen, married at twenty-eight, and had six children, the last of whom she bore when she was forty-eight. She suckled this child, and saw no catamenia afterwards. On March, 1863 (viz. twenty-four years after the last catamenia, she menstruated for three days, and the same happened on the 2d of April and the 4th of May. She then consulted her doctor, being afraid of cancer. On examination she was found quite sound. In June and July the catamenia appeared again. In August they lasted but one day; and, at the close of this month, as well as in September, the patient had some sickness of stomach, a circumstance to which she paid but little attention. On October 26th she sent, in great haste, for the doctor; and it was found that she had had labor pains. Having experienced a kind of sensation as for an evacuation per rectum, she had felt something rather bulky pass per vulvam, with much liquid. The latter was serum mixed with blood, wherein a two-months' fœtus was floating. The placenta was discharged two days afterwards, and the patient did very well. She died, however, three months afterwards of extensive bronchitis.—*Lancet.*

The supply of Iodine and Bromine.—Iodine occurs in commerce much more abundantly than bromine, and hence does not command so high a price as the latter element. A ton of raw sea-weed yields about a quarter of a pound of iodine, but not more than half an ounce of bromine. The water of the Dead Sea has long been known to be exceedingly rich in bromine, without containing, so far as could be ascertained by the old methods of analysis, the least trace of iodine; and Mitscherlisch has not only failed to detect, by the delicate process of spectrum analysis, the minutest portion of iodine in the water of this sea, but he has also failed to detect iodine in European sea water, containing a very appreciable quantity of bromine. For example, he found that the residue from the evaporation of six and a half pounds of sea-water taken off Heligoland, treated by his process, showed the bromide of copper spectrum for seven minutes, but did not give the least sign of the iodine spectrum.

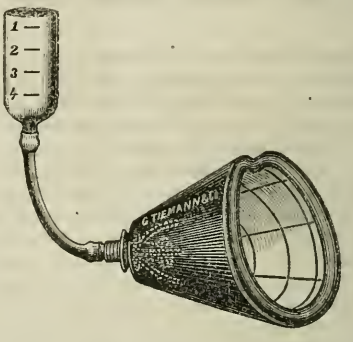
Improvements in Instruments.

A NEW INHALER FOR ETHER.

By FREDERICK D. LENTE, M.D.

Of Cold Spring, N. Y.

The object of the invention of the "inhaler," of which a delineation is here given, is mainly to encourage a more general use of "*ether*" as being the safer anæsthetic, it having fallen into very general disuse in this country since the introduction of *chloroform*, and into almost total abandonment in England. The reason commonly alleged for this is the "*difficulty and uncertainty*" of inducing anæsthesia, and the large amount both of *time and material* required. I confidently claim to have completely obviated all these objections by the simple contrivance now presented to the profession.



It consists, first, of a light wire, helmet-shaped framework, so formed at the base, which is bound with a soft cushion, as to fit over the nose and chin, but not to cover the eyes. At the apex of this cone, is a male screw; over this framework is a cone of double flannel, —a hole at its apex allowing it to slip over the screw. Over this is screwed an arrangement consisting of a short tube about half an inch in diameter, and branching into three smaller tubes, so arranged, when adjusted, as to embrace and open upon the flannel cone at equal distances from each other, at about one-third of the height of the cone. Over this tube is slipped a cone of tin or of some impervious material not easily acted on by "ether." The cone is kept *in situ* by a nut screwing over the tube; over the end of the latter is drawn a rubber tube about half an inch in diameter, the other end of which is to be slipped over the neck of a suitable bottle containing about four ounces of ether, as soon as the inhaler is required for use; or over the end of a metal tube fitted to a cork which may be attached to any bottle, but the other mode of connexion is the safer.

Having explained to the patient the manner of breathing, viz. to inhale as *rapidly and fully* as possible, as long as he retains consciousness, and *not to be alarmed* by any unpleasant sensations which may be excited at first, the cone is fitted as accurately as possible to the face; the wire and tin being bent a trifle, if necessary; and, as a *sine qua non* of the successful use of the instrument, I insist that, having been once placed on the face, it is to be kept *closely* applied, and never once removed, ever so little, until anæsthesia is complete. * Of course there may be now and then, but

* By placing the inhaler over his own face as tightly as possible, without ether, and breathing through it, the operator may convince himself that there is no danger of suffocating the patient by cutting off too much air, as it is impossible to prevent the leakage of a sufficient amount for tolerably free respiration.

rarely, an exception to this, as when a patient persistently holds his breath for some seconds; but the moment he commences to respire, it is to be replaced. Upon inverting the bottle and holding it above the inhaler, the ether runs very rapidly through the tubes, and almost immediately diffuses itself over the whole flannel cone, no matter whether the instrument is held *vertically or horizontally*. For commencing, about two drachms is a sufficient charge; as soon as the patient begins to respire fully, or in twenty or thirty seconds, about three drachms more are to be applied, and so on until the etherization is complete; if a larger amount be used, it is of no consequence whatever, except as regards the waste of ether; if more than enough is used, it will run down and be felt by the fingers at the bottom of the instrument. When the inhaler is removed from the face, from time to time, as when stertorous breathing comes on, it should be placed base downwards on the bed or operating table, which will save ether and prevent annoyance, to a certain extent, from the escape of the vapor.

Advantages of the Apparatus over the Ordinary Methods.—1st.—Entire safety. There need be no care regarding the *due admixture of air*, as the size of the cone is so adjusted that enough of air will find its way through the crevices, and between the face and the instrument, to insure this condition, *in spite of* all endeavors to prevent it. 2d.—The patient breathes with comparative *comfort*, and very rarely struggles or resists; first, because the ether can never touch the face; and secondly, because there is always a *uniform* admixture of air, on account of the unvarying capacity of the cone. With the *towel cone*, on the contrary, or with the *sponge*, the capacity of the cone is constantly in danger of being diminished, indeed is necessarily diminished, through the pressure exerted upon it by the hands in holding it firmly to the face; especially during the struggles which are almost always excited when ether is given in this way. Sometimes, from want of attention, it is almost completely obliterated, and the patient in danger of mechanical suffocation, which is often wrongfully attributed to the irritating effects of the vapor of ether. To this cause, and to that which will be alluded to in the next paragraph, may be ascribed, in a great measure, all the failures in administering ether. 3d—There is no necessity *ever to raise the apparatus from the face after it has been once applied*, until the patient is thoroughly relaxed or breathing stertorously. In applying ether by apparatus heretofore in use, the latter is withdrawn every now and then from the face to replenish the ether, and this is generally done so deliberately that an inspiration of fresh air is effected, which, with an agent so feeble, comparatively speaking, as this, greatly retards the process. 4th—There is but little danger from fire, when operating by artificial light, there being no necessary escape of a dangerous amount of vapor, and no danger of spilling ether in upsetting the bottle or while pouring it into the inhaler. Several accidents have been reported from this cause, both in hospitals, and in private practice, in the care of well known surgeons. 5th—The operator and assistants, when operating about the face or upper part of the body, are almost completely protected from the inhalation of the surplus vapor which proceeds, in a greater or less degree, from all the ordinary contrivances, no mean advantage to many surgeons who are seriously incommoded by even a small amount of vapor. 6th—Saving of ether, a matter of considerable importance in hospitals, at its present price. An ounce or two is sufficient where one has become accustomed to using the inhaler. 7th—Saving of time, though this is not of so much consequence. From two to four minutes is as much as any one should require. 8th—The etherization may be intrusted, where assistants are scarce, as is frequently the case in country practice, to any sensible unprofessional person; since the amount of air required is always regulated by the instrument itself. 9th—Facility for cleansing; by simply unscrewing a nut, the parts may be separated from each other. The flannel should be well washed whenever it is soiled by saliva or blood, or it has an unpleasant odor.

Before we commence to use *ether*, we should be fully impressed with the *fact* that it *never* acts in the *sudden* and uncontrollable manner by which chloroform kills most, if not all its victims. It is impossible to do this. In most of the cases where death has been ascribed to ether inhalation, the untoward result has occurred from four days to even three weeks after the operation; in which cases I consider it simply absurd to attribute this to any anæsthetic, ether or chloroform. Within a few hours, I have no doubt it may occur, even after the patient has recovered consciousness perfectly; but here the matter is under the control of a surgeon, and there is time to interfere and prevent the fatal result; and when a surgeon leaves his patient, especially if he be debilitated, or of strumous habit, or has a particularly feeble or irregular pulse, within less than half an hour after the operation, without leaving a competent medical man with him, death should not be laid at the door of the anæsthetic. I have had to use stimulants freely (sometimes *per rectum*, when vomiting supervened) in such cases.

A matter of the first importance is to have a *pure ether*. I have no experience with any but that manufactured by Dr. Squibb, although I do not wish to insinuate that the production of other eminent manufacturers may not be good. The elaborate report of the Committee of the "Boston Society for Medical Improvement," asserts that this ether is so pure and anhydrous as to produce irritation, and that it is not so respirable as Powers and Weightman's. I have never had any trouble with it; at least, never since using it with an inhaler, and would advise all to use the purest and most concentrated article.

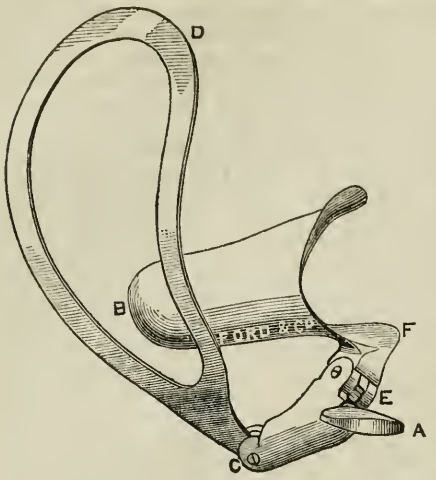
Another important preliminary to the administration of an anæsthetic is to have the stomach empty; to allow only a *very light* meal, *several hours* before, remembering that when the mind is disturbed by the apprehension of an operation, or even by that of anæsthesia alone, digestion is slow, if not entirely arrested. Although there is no considerable danger in giving it on a comparatively full stomach. Also, in cases of debility, or strumous habit, or excessive alarm, to allow a stimulant a few minutes before commencing the inhalation.

EMMET'S PERINEAL RETRACTOR FOR VAGINAL EXAMINATIONS.

Dr. Emmet, Surgeon to the Woman's Hospital of this city, has furnished us with the following description of his speculum:—

"This instrument brings the neck of the uterus into view, as with Sims's speculum, by retraction of the perineum, but with the advantage that an assistant is unnecessary. The patient should be placed in the same position on the left side, the lower limbs flexed well on the abdomen, with the upper or right leg in advance of the under one; the lower, or left arm, withdrawn from under the body, and flexed across the back, so as to rotate the chest as flat as possible on the table or operating chair. The proper position is absolutely necessary in the use of both instruments; and without it is observed in detail, a great advantage is lost. When properly ap-

plied, either will expose a larger portion of the vagina than can be done by any other instrument in use.



"After separating the instrument fully, the fenestrated blade, *D*, is turned up as represented in the cut; the vaginal portion is then introduced on the index finger of the right hand, at the same time the perineum is pushed backwards, and the instrument held firmly in position, while the thumb-screw, *A*, is turned by the other hand, until the instrument is adjusted. By the thumb-screw, the point, *B*, of the speculum is carried into the hollow of the sacrum; with the joint at *C*, the blade *D* can be adjusted on the right buttock; by carrying it in the direction *D*, as the lower portion of the instrument in the line *C*, *E*, *F* rests on the lower buttock, along the sulcus, and the vaginal portion is in the shape of a cone, the upper labium of the vagina is elevated. If the cervix uteri is not brought into view at once, a depressor may be needed to push aside the anterior wall, although as a rule it is not necessary. By elevating slightly the instrument at *F*, the point *B* becomes depressed so as to bring the neck often into view, when not presenting. As it is impossible to have a single blade of a size to answer for every case, as with Sims's speculum, a little manipulation is frequently needed when the vagina is unusually long or its wall relaxed; a depressor is therefore required; when once the neck is brought into view, it should be seized by a tenaculum, and drawn in advance of the fold, and it generally remains in position afterwards. The tenaculum may remain hooked into the cervix, as it is absolutely necessary to steady the organ properly during any manipulation, even when the neck is brought into view at once.

"I have used this instrument for the treatment of uterine disease, and for different surgical operations on the base of the bladder, with the greatest satisfaction. Having an experienced female assistant, who has been long accustomed to the use of Sims's speculum, I shall continue to use his instrument to a great extent in my office practice, from the fact that it is applied as soon as introduced. But for an examination without the aid of an assistant, and for long operations, this instrument, when properly applied, affords so great a facility, that I believe, after one has become familiar with its use, it will take the place of all others. It gives no pain, from the fact that the perineum is compressed to one side of the coccyx; and from the steadiness with which the retraction is maintained, I have found that this instrument is preferred to the jerking and unsteady handling of Sims's speculum by an assistant unaccustomed to its use.

"I am greatly indebted to the skill and perseverance of Ford & Co., of Fulton street, for putting into practice the principle, after many disappointments and modifications of the mechanical application. They have so constructed the instrument that one of several blades of different sizes can be attached at the joint *E* when required, although an average size has been fixed upon as the standard, which will answer for nearly every case by a little dexterity on the part of the operator."

Correspondence.

THE CHICAGO MEDICAL COLLEGE; THE CHICAGO MEDICAL SOCIETY, ETC.

Chicago, April, 1866.

To the Editor of the Medical Record.

Sir:—Since the date of my last letter, the seventh annual commencement of the Chicago Medical College has occurred. Twenty-two students were graduated; the *ad eundem* degree of Doctor of Medicine was conferred upon four candidates, and the honorary degree upon five. Prof. Byford delivered to the departing class a valedictory address, which was characterized by the good sense and true wisdom which mark all the utterances of this sagacious physician. His theme was entitled "The Philosophy of Trades and Professions"—a subject which gave ample scope for witty and happy comparisons between the influence of the practice of medicine and of the other callings which are pursued through life by the majority of mankind. In conclusion, however, the Professor sought to impress upon his hearers the fact that it matters not so much what one does as how it is done; the direction of one's effort is of greater importance than its degree: if true goodness and greatness constitute the ends in view, they may be attained through many various ways.

The College appears to be in very prosperous circumstances, considering its youth and the overshadowing prestige which still attaches to the Rush School. The course of instruction is arranged upon a methodical and scientific basis, far in advance of the majority of American medical schools. The undergraduates are classified into a Junior Class for the students of the first year, and a Senior Class for those advanced students who have successfully passed the examinations which conclude the junior year. By this arrangement, which is not merely nominal, but is rigidly enforced by the Faculty, the scandalous spectacle presented by an obstetrical lecture-room crowded with gaping greenhorns who cannot yet enumerate the bones of the body, is wholly avoided. In addition to a winter term of twenty weeks, there is a long summer term of lectures and clinical instruction by the college professors, which is in advance of anything elsewhere afforded in the Northwestern States.

The Chicago Medical Society has continued its weekly meetings through the past winter. Each alternate meeting is occupied as a pathological session, when the members exhibit whatever specimens of morbid anatomy they have procured during the previous fortnight, and also relate the particulars of any interesting cases which may have passed under their observation. The intervening evenings are devoted to the formal discussion of medical topics. During the past two months the time of the Society has been engrossed by the discussion of cholera. This interesting theme has secured a full attendance of the members. The pathology and treatment of the disease have thus far been dwelt upon at considerable length. At the next meeting the ques-

tions of contagion, quarantine, and cholera hospitals will be reviewed. The discussions have, so far, contributed little that is new in respect of the methods of dealing with the formidable pestilence. Prof. N. S. Davis recommends the use of nitrous oxide gas as a vital stimulant, to supply oxygen freely to the blood, and to relieve spasm and vomiting. Arguing from the effects of this gas in cases of syncope, the professor thinks it may be very beneficial in almost every stage of cholera. One fact which has been developed by this discussion is worthy of note: while the older practitioners who have passed through previous epidemics are unanimous in advocating the use of measures to arrest vomiting and purging, there is manifest among some of the younger members a disposition to regard these evacuations as fraught with safety rather than danger to the patient, and as indications of an eliminative effort which should only be opposed after the restoration of the natural processes of excretion. The whole matter of difference seems to turn upon the question of the nature of the disease. If it consists merely in a derangement of the nervous functions, the anti-evacuant and neurotic method of treatment must be most efficacious; but if it results from the intrusion of a specific poison which vitiates the watery portion of the blood to such a degree that the system can no longer tolerate its presence, that method which sustains the vitality of the patient, while it favors rather than opposes the efforts of nature, will be most serviceable. The terrible results of the stimulant and anti-evacuant treatment during previous epidemics, seem to indicate that any method which shall attempt to guide and to assist the natural processes of the disease is worthy of trial.

While the medical profession thus displays an enthusiasm which is most commendable, our public functionaries have relapsed into a deplorable condition of apathy. Agitated by the report of cholera at the New York quarantine ground, and instigated by the Chicago Medical Society, the city fathers issued a ukase which was printed and distributed to every house, at an early period of the winter, forbidding the discharge of kitchen refuse upon the streets and alleys of the city, and commanding a daily production of slop-pails, which would be called for by the public scavengers. Accordingly, on the day appointed for the inauguration of cleanliness, the curb-stones throughout the town were lined with an edifying row of kegs, cans, and pails, overflowing with cabbage-stalks, potato-parings, and soap-grease The advent of the new scavenger-wagons was anxiously awaited by the little folks, who flattened their noses all day against the window-panes, in their efforts to discover the promised apparition. Evening came, and the next morning, too, but still the unemptied tubs kept silent watch along the street. Several days elapsed before the magnitude of the joke was comprehended by the citizens. It was at length discovered that the whole scavenger troop was limited to ten dilapidated army-wagons and twenty spavined nags, which were incapable of active service outside of the city stables. For a population of nearly two hundred thousand souls the inadequacy of this provision was so ludicrously evident that all thoughts of sanitary reformation were hastily abandoned; the servant girls relapsed into the municipal custom of depositing the waste of the household in the streets and alleys; and we are reduced to our former dependence upon those faithful friends of man, the rats. We congratulate you of New York upon your Metropolitan Health Commission. It will not be many years before we shall resort to a similar organization, for Western people are not slow to adopt new improvements; but until that fortunate time, it will not be through any hygienic precautions that the healthy reputation of our city will be sustained. Yours, &c., M.

COMPLETE DISLOCATION OF THE HEAD OF THE TIBIA FORWARDS.

To the Editor of the Medical Record.

Sir: The following case has been communicated to me by Mr. John H. Harris, Medical Student at Bellevue. It is reported with so much clearness and intelligence that I have thought it best to send it to you for publication. The principal point of interest in the case is the great relief given by extension. The amount of extension employed was nine pounds, applied in the same manner as in Buck's apparatus for fracture of the femur. Very truly yours, Frank H. Hamilton.

"As accidents of this kind are exceedingly rare, I have made a record of the following interesting case, which came into my hands for treatment:

"On the 19th of March last I was called to see Hiram Weseott of Sandy Cove, N.S., a farmer, aged forty-five, who had a dislocation of the head of the tibia forwards. This man was standing between the beams of a shed, when the team suddenly starting, his heel was caught upon a small stump, and one of the beams striking him a short distance above the knee, his body was thrown forwards, producing a dislocation at the knee-joint. The femur was driven backwards and downwards, while the tibia looked forwards very nearly at an angle of forty degrees. The tendons of the hamstring muscle were not ruptured, but had slidden forwards past the condyle of the femur. Reduction was quite easily effected by extension, and without very much pain to the patient. After reduction I applied pasteboard splints, and in the course of an hour the patient expressed himself as quite comfortable.

"On the next day I saw the patient again; he was quite comfortable, but had been somewhat restless through the night. Sunday the 12th, three days after the accident, I removed the splints, and upon examination found the limb about the knee considerably swollen, and some ecchymosis in the popliteal region. Up to this time the patient had experienced little or no pain except during the night; but, contrary to my instructions, he had been moving about with the aid of his crutches. I again applied the splints, and left him quite comfortable.

"Tuesday, the 14th, I was early summoned to see the patient, and found him suffering from all the symptoms of acute synovitis, with the ecchymosis much more marked in the popliteal region. I at once proceeded to apply extension by means of a weight and pulley, which gave immediate relief.

"Visited the patient on the 17th, and found him comfortable so long as extension was kept up; but if it was removed, the pain would instantly return with great severity. The extension was kept up for several days until all trace of inflammation had subsided, when I allowed the patient to move about with the aid of his crutches, occasionally removing the splints to give passive motion to the knee-joint.

"After the lapse of ten or twelve weeks from the date of the injury, the splints were removed and an elastic knee-cap substituted. From this time the patient continued to improve, and was enabled to walk about with his cane. At the expiration of about four months from the time of the injury, he had so far recovered as to lay aside his cane and resume his occupation. With the aid of the elastic knee-cap he can now walk without any difficulty or perceptible limp.

"John H. Harris,
"*Sandy Cove, Nova Scotia.*"

INJECTIONS IN CHOLERA.

To the Editor of the Medical Record.

Sir:—Cholera is reported on shipboard at quarantine, and we may expect it in the city at any moment.

Most of our medical gentlemen have had experience in cholera, and have formed their plans of treatment, while others have not. To those who are undecided, I beg to say, the moment you get a case with the *characteristic watery stools*, put him in bed, and administer to him an injection containing two ounces of good brandy, and two ounces of strong coffee or tea.

Whether he is vomiting or not, put a mustard plaster over the epigastrium, and let it extend down over the abdomen. If he is thirsty, let him have ice in the mouth continually. Keep him in bed, and keep him warm, if possible.

If he will get up to stool, put him in bed again at once, and give another injection of the same kind and quantity. If he has cramps in the extremities, rub with dry flannel. Give no opium at all, unless there is considerable pain in the stomach or bowels; and then give but little, combined with small doses of calomel. Repeat the injection after each stool, and in a very short time the bowels will be checked, and you will have the gratification of seeing your patient out of any immediate danger.

If the watery stools at any time return, use the injection again as before. If the bowels have been checked for a considerable time, and you have given a number of doses of calomel, it will be safe to give a potion of castor oil, if it is deemed necessary.

This, in a few words, was my experience in the epidemic of 1854, not only in the cholera hospitals, but in private practice. In no case did this treatment fail to arrest the watery stools, when it was faithfully carried out; and the earlier you commence the treatment, the better it will be for your patient. If you can arrest early the rice-water stools, and keep them under control, you cannot have a very bad case of cholera, as a general rule.

We hear and read of cholera that destroys life very quickly, *without* any *purging* or *vomiting*. I confess I have never seen such cases, and I saw a great deal of the disease in 1849 and 1854.

If such cases occur, and possibly they do, the cholera poison must act upon other portions of the nervous system than were described by Prof. Clark in his learned lectures on cholera before his class, and which you are publishing in your excellent Medical Journal. Dr. Clark says: "The first perceptible effects of the cholera poison are upon the ganglionic nervous system, and especially upon that portion of the ganglionic system that presides over the alimentary canal, producing paralysis of those nerves; and the result is congestion of the mucous membrane of the intestines, and pouring out abundantly of water." Now if the cholera poison really destroys life without giving any of the characteristic dejections of cholera, then the poison must act upon other portions of the ganglionic nervous system which are not fully understood, or at least which are yet unexplained.

We go back to the treatment. If there is paralysis of that portion of the nervous system which presides over the alimentary canal, producing congestion of the intestines and serous hæmorrhage, why should not brandy or any other stimulant thrown into the bowels stimulate and restore that lost power, and again place the alimentary canal under normal and physiological control?

This paralysis is not the result of organic disease, but is *functional*, and the result of a poison introduced into the blood through the medium of a poisoned atmosphere; and why may not this paralysis be restored by direct stimulation? Whether this reasoning is good or bad, I hope it will not alter the effects of brandy injections in the treatment of cholera.

It should be remarked that the distressing and persistent vomiting ceases with the cessation of the watery stools; and then such medicines and stimulants as are considered necessary may be administered by the stomach. If the medical profession try this treatment, and find it good for nothing, they will abandon it.

If, on the other hand, they find it will control the purging and vomiting of cholera, they will feel that they are armed with a most valuable weapon, and one that will aid them greatly in overcoming a most formidable disease.

O. H. Smith, M.D.

New York, April 20.

THE N. Y. COUNTY MEDICAL SOCIETY (?)

To the Editor of the Medical Record.

Sir,—I almost failed to recognise my time-honored friend, "The New York County Medical Society" under your unusual designation in the report of its last month's proceedings, of the "Medical Society of the County of New York." Can you produce any authority for this violent change in the nomenclature? Why not with equal propriety say the "Medical Society of the County of Kings," of Queens, etc., etc.? The society has certainly gained all its prestige under the terse, compact name of the New York County Medical, and not under the awkward, unmusical one recently sought to be given it. I pray you, therefore, Mr. Editor, to desist from your iconoclastic tilts at authority both written and traditional, and return with all possible speed to the good old usage, while to retreat may yet be accounted masterly.

U.

New York, April 27th, 1866.

TREATMENT OF GLEET AND DISEASES OF THE PROSTATE BY CATHETERIZATION AND LOCAL APPLICATION.

To the Editor of the Medical Record.

Sir:—There are probably few diseases so intractable to treatment and so discouraging to the practitioner as some of the many deranged conditions of the prostate gland. Even the most successful of internal remedies are but too frequently uncertain, and injections by the ordinary syringe often fail to reach the diseased part. In order, therefore, to apply the intended remedy directly to the prostate, or to any part of the urethra which may require a local application, I have used the common vulcanized India-rubber syringe, to the nozzle of which I attach the curved half of an ordinary metallic catheter, with an opening at the point instead of at the side. I then introduce the instrument (previously filled with the liquid to be injected) until its extremity comes in contact with the diseased surface, and then inject its contents directly over the part requiring its application. Besides the advantage above shown, this instrument enables one, especially in cases of gleet, and even gonorrhœa, to discover the exact location of the ulcerated or otherwise diseased surface; and, at the same time, by frequent introduction, prevents the walls adhering together and thereby forming a stricture.

In every case in which I have used this instrument I have met with the happiest results, not having failed in any instance as yet to effect a complete cure. I would also state that by this method, the injection used need not be nearly so strong as that required by the ordinary syringe.

Yours, &c.,

H. Ellsworth Davis, M.D.

New York, April 2, 1864.

APPOINTMENTS.

UNIVERSITY MEDICAL COLLEGE, N.Y.—Dr. W. H. VAN BUREN has resigned his professorship of Anatomy in this institution, and Dr. W. Darling, of London, has been elected to fill the vacancy thus created. Dr. John T. Metcalfe has also resigned his professorship of Practice of Medicine and Pathology, and Dr. A. L. Loomis has been nominated to fill the chair.

BELLEVUE HOSPITAL MEDICAL COLLEGE.—Dr. H. G. PIFFARD has been appointed assistant to the chair of Practical Medicine and Pathology.

Dr. JAMES L. BROWN has been appointed to conduct the class of Diseases of Women in the Demilt Dispensary, vice Dr. E. R. Peaslee, resigned.

PERSONAL.

PROF. JOHN W. DRAPER, of the University Medical College, has been complimented by a translation of his work on "The Intellectual Development of Europe," into Dutch, Italian, and German. His "Future Civil Policy of America" has also been translated into German by Mr. Bartels, Librarian in Wolfenbüttel, and is issued by a Leipsic firm. His forthcoming "History of the American Civil War" will be produced in England, France, and Germany, simultaneously with its appearance in America.

ON SURGICAL MALPRACTICE.—Prof. George C. Blackman of Cincinnati, aided by Hon. Stanley Mathews, has undertaken the preparation of a volume on surgical malpractice. It is announced that it will probably be ready early in the fall.

Dr. THOMAS WATSON, of London, has been unanimously elected for the fifth time President of the Royal College of Physicians.

DR. WM. A. HAMMOND, ex-Surgeon-General, U.S.A. is at present in Paris, having registered at the office of Bowles, Drevet & Co., 24 Rue de la Paix, on the 6th ultimo.

DEATH OF PROF. JOSEPH M. SMITH.—We are called upon to make the painful announcement of the death of Professor Joseph Mather Smith, which took place at his residence on the morning of April 22. We shall present our readers with a sketch of the life of this distinguished physician, at some future time. He was seventy-seven years of age at the time of his death.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.—At the next stated meeting, May 7, 1866, Dr. Wm. H. Thomson will read the concluding portion of his paper on Chlorosis, referring mainly to its treatment. Dr. Chas. F. Taylor will read a paper, entitled "The Initial Cause of Uncomplicated Lateral Curvature of the Spine."

SOCIETY FOR THE PREVENTION OF CRUELTY TO ANIMALS.—This Association held its first meeting in N. Y., April 23d, and organized by appointing his honor the Mayor temporary chairman. The act incorporating the society was read. The following officers were then elected: *President*, Mr. Bergh; *Vice-Presidents*, Hon. J. T. Hoffman, Rev. H. W. Bellows, Peter Cooper, Hon. George Bancroft, Charles P. Daly, Geo. T. Trimble, Esq., William H. Aspinwall, Esq., Moses Taylor, Esq., Marshal O. Roberts, Esq., and Alex. T. Stewart; *Secretary*, W. C. H. Waddell, Esq.

THE INTERNATIONAL SANITARY CONFERENCE, created at the suggestion of the French Emperor, is now in session at Constantinople, and engaged in the investigation of the origin of the choleraic epidemic, which last summer swept away some fifty thousand of the inhabitants of that city.

Its members are subaltern officers of the legations resident in Constantinople, with the exception of the French and Portuguese representatives, whose diplomatic rank is much higher; and they only seek medical opinions as emergent questions or technical disputes arise. Certain radical defects in the organization, according to some authorities, have by no means tended to produce harmony in counsel.

Meanwhile the Sublime Porte has sent a commission of his own to Mecca, Medina, and other holy places in Arabia, who are now occupying themselves with hygienic expedients, among which will probably be the proper burial of the large number of animals sacrificed on the occasion of the Mahommedan pilgrimages.

The attention of the authorities has also been called to the fact, that the greater part of the Turkish victims have been interred not more than two feet beneath the soil. In view of the alleged fact, that owing to the rigid quarantine the islands in the Archipelago and Greece proper were unvisited by cholera, it is proposed to exercise more than ordinary vigilance in bringing the tide of human travel under the government of still more stringent laws.

CHOLERA AT QUARANTINE, N. Y.—The steamship Virginia arrived at this port on the 18th ult., with Asiatic Cholera on board. No cases of the disease, which broke out during the passage, and were over one hundred in number, were reported as having occurred among the cabin passengers. The vessel now lies quarantined in the "Horseshoe," just this side of Sandy Hook, and the hospital ship is anchored close by her. The well passengers were removed to the steamer Illinois, with the exception of those in the cabin, who remained in their old quarters on board of the Virginia. The total number of deaths up to our hour of going to press, was fifty-two, with seventy-nine still on the sick list.

Cholera at Halifax Quarantine.—The following is an extract from a private letter which we received from Halifax, bearing date April 17:

"I suppose you have heard that we have a cholera ship in port. *There is no doubt as to the disease being cholera, and of a severe type*, although I notice it has been denied in some of your papers. Up to the 14th two hundred had died. Few if any new cases have occurred since she was taken in charge of by the health officers; although the pilot who brought her to this port, and family have been down with it; one of them died. Our quarantine station is only three miles from the city, so that we are likely to have it here before long.

"I have just heard that one health officer died on shipboard last night."

Cholera has again broken out in the country districts of Guadaloupe. The medical staff has been augmented, and a commission appointed to make inquiries and point out a remedy for the epidemic.—*Lancet*, April 7, 1866.

Cincinnati Academy of Medicine.—The annual election of officers resulted in the choice of the following gentlemen: Dr Thomas Carroll, President; Dr. Chas. Woodward, Vice-President, and Dr. Graff, Secretary.

Metropolitan Police Surgeons.—An act enabling the Police Commissioners to appoint an additional number of surgeons passed the Legislature on the 12th ult. In accordance with the adopted recommendation of the Conference Committee on the bill to regulate the salaries of the Metropolitan Police, they will receive $2,250 per annum.

Dysentery in Canada.—We learn from exchanges that our Canadian neighbors are viewing with alarm certain dysenteric tendencies in their midst, and are clamorous for a rigid quarantine to prevent the introduction of any epidemic into their cities from abroad.

The Health of Washington, D. C.—Small-pox has been prevailing in the city to a considerable extent. One or more schools have been broken up in consequence. The physicians of the city report a large increased percentage of sickness arising from derangement of the bowels. Sanitary precautions to prevent the appearance of cholera are enlisting discussion, but as yet little or no action has been taken by individuals or city authorities. In view of the probability of an approaching sickly summer, the adjournment of Congress between this and the middle of June is looked upon as a certainty.

Scurvy is reported to be quite prevalent in the British mercantile navy.

A New Hospital.—The Battery barracks have been transferred by the general government to the Board of Health for Hospital purposes.

Excise Powers of the Health Commission.—Our announcement in the previous issue of the passage of the bill conferring the exclusive power to grant licenses for the sale of liquors upon the Metropolitan Board of Health, was, as far as the date was concerned, premature. This desirable result was not in fact accomplished until the 13th ult., when the House recorded its verdict by 66 ayes against 31 nays. This bill requires all policemen to report the names of persons selling liquor within their respective beats, and authorizes the employment of the police force to execute the provisions of the act. The Health Commissioners accordingly organized as a Board of Excise on the 20th ult., when it was determined that no member on duty under the original board should act as Inspector of Excise.

Model of Hicks U. S. A. Hospital, Baltimore.—Surgeon-General Barnes, U.S.A., has recently had constructed a very beautiful model of the Hicks U. S. General Hospital, at Baltimore, Md., which is designed to be sent to France for exhibition at the Paris Exposition in 1867. The model is made of wood, and is on the scale of one inch to twenty feet.

Sanitary Condition of Key West, Florida.—According to advices of the 7th ult. from the above-named city, under the signatures of the Mayor, the municipal and U. S. health officers, there is no truth in the reports that cholera, yellow fever, or other epidemic diseases exist there. These officials state that, on the contrary, the public health has been unusually good.

The Medico-Historical Society are engaged in collecting materials for their fourth "Annual Medical Register," which will appear in June next, under the editorial management of Dr. Guido Furman.

Hippophagy in Berlin.—Great success has attended the introduction of horse-flesh in Berlin as an article of human food. In 1865, two thousand two hundred and forty-one horses were slaughtered for this purpose. The meat is perfectly wholesome and tolerably palatable, resembling rather coarse beef.—*Lancet.*

The State Woman's Hospital.—In our last issue we noticed the action of the City Council in revoking the grant of land made by the city authorities some years ago, to the Board of Governors of this Hospital, on the ground that the institution had never entered into possession. Before a final action was taken by the Board of Aldermen, it was shown that the issue was a false one. On being referred back under the circumstances for reconsideration, the Common Council rescinded the previous act. This land was at one time used as a Potter's Field, and after the removal of the remains to Ward's Island the board has been for several years past occupied in preparing a site by lowering the grade some fifteen or twenty feet to a level with the street. A building, on the corner of Fiftieth street and Fourth Avenue was commenced last year, and will be finished next fall. It will contain about one hundred beds, a large operating or lecture-room, and in every respect will be complete in itself as a model hospital. The plan has been drawn with great care, so as to embody all the modern improvements, and is to consist of a centre building, with one on each corner of the block. The whole will constitute, it is claimed, one of the finest hospitals ever erected in this city, with accommodation for some four hundred patients. The managers will continue to occupy the institution on Madison Avenue until this portion in process of erection is completed.

Destructive Mule Distemper.—A frightful mortality is reported among the mules on the various plantations bordering on the Mississippi. No less than two thousand in the vicinity of Vicksburg have died within a period of forty-eight hours. The disease is represented as having severe colicky symptoms, which speedily prove fatal. Precautionary measures are being taken by the planters to prevent its spread.

Original Communications.

DISINFECTANTS.

By EDWARD R. SQUIBB, M.D.,
OF BROOKLYN.

(Concluded from page 102.)

These illustrations are particularly intended to show, first, that the best, if not the only, way to prevent pestilential fermentation is to prevent the formation of, or to remove, that pabulum which is essential to the process, namely, filth; and, second, as absolute cleanliness cannot be at once attained, if at all, in communities like this, to show by what kind or character of agencies these hurtful reactions must be controlled. It was also shown that many of these reactions are so delicate and sensitive in character that they may be modified, suspended, or even destroyed, by a great number of agents—indeed by almost everything which materially modifies the condition of the pabulum. The principal difficulty, then, consists not in the selection of a disinfectant, since all are effective, even the most opposite in character, but rather in the adequate application of a process of disinfection; for once started, with a widely diffused pabulum that is always receiving new accessions, the fermentation increases and spreads with a rapidity that soon leaves the best directed efforts at general disinfection far behind. Any disinfectant then becomes useful in proportion to the scale upon which it can be practically applied; and such application depends largely upon the simplicity, cheapness, and abundance of the agent, particularly in time of epidemic disease. Except for individual and special uses, and these in the houses of the better and more cleanly classes, where perhaps they are rarely needed, a large class of the most active agents, as bromine, permanganates, etc., are out of the question; while even chlorine, the sulphates of iron and copper, carbolic acid, and the patented powders and liquids, taken altogether, fall far short of the desirable universality. Archimedes, to move the world, must have a long lever as well as a strong one.

In coming to the consideration of the prominent special agencies for disinfection, in special as well as general cases, it is well to remember first, that:

A plentiful supply of water and air, and a good system of sewage and drainage as inducements to cleanliness, and a good police, directed with knowledge and armed with power, must always be regarded, and can alone be considered as effectually disinfectant for cities. But such police, as well as the private citizen, will often need auxiliary means for special cases and purposes, as well as for general and public use; and their auxiliary and secondary character should never be lost sight of. It may be regarded as a sanitary axiom that natural disinfection, whereby the greatest practicable cleansing is attained, should always precede every attempt at artificial disinfection. Then the greatest cleanliness having been attained, and the special purposes accomplished by the special agents, the field of application for the general disinfectants is narrowed within its most practicable and most manageable limits. These principles of disinfection established and borne well in remembrance, it can only be necessary to refer in a cursory manner to the newer applications of one or two of the special agents, and then merely to enumerate others, somewhat in the order of their importance, in approaching the main object of the paper.

For very nice use in disinfecting and deodorizing the air of a sick-chamber, where the odor of other gaseous disinfectants would be more objectionable, a well regulated elimination of ozone, by means of phosphorus, may be resorted to with success.

A stick of phosphorus, or half of a stick for an ordinary chamber, laid upon the flat surface of an ordinary tea or breakfast plate, and water enough poured upon the plate to immerse two-thirds of the stick, leaving the remainder exposed to the air; and the plate then placed upon a table or mantelpiece out of the reach of accident or disturbance, and yet where it is under constant observation, constitute the materials and conditions proper to accomplish this. That portion of the phosphorus which is immersed undergoes no change, and produces no effect; and therefore the effect to be produced may be easily regulated by adding and abstracting water, and thereby exposing more or less of the phosphorus to the moist air. For example, in a sick-chamber during the day, where the opening of doors and the movements of attendants tends to greater disturbance and change of the air, the cylinder of phosphorus may be left one-third or more exposed above the surface of the water, at least until the odor of phosphorous acid becomes disagreeable. Then at night, when the chamber is to be closed and still, more water is poured upon the plate, until perhaps but a line of the cylinder is exposed above the surface. By morning the evaporation of the water will have increased the amount of surface exposed; but if not sufficiently, some of the water may be dipped out of the plate to produce the increased daytime effect. When the desired disinfection has been accomplished, and the action is to be suspended for a day or two, the simple filling the plate up with water until the whole stick is immersed accomplishes that end. In the dark the exposed portion of the phosphorus shines, casting a somewhat lurid light around the apartment, and the vapors arising from it are visible and moving. This latter effect particularly should be hidden from the view of the patient, since, whether there be a tendency to delirium or not, the half-sleeping mental condition of most sick persons is very impressible, and may be injuriously affected thereby. Phosphorus, from its easy inflammability, is a dangerous substance at best, and therefore this means of disinfection is never perfectly safe, and can only be judiciously adopted under the direction of a medical man who will take the time to think what he is doing, and the pains to give proper directions and cautions, and who knows the responsibility and risk which he assumes. An accident by which the phosphorus, whether in buying it, using it, or in keeping for after use, may be allowed to become dry, will result in its spontaneous combustion, and in setting fire to anything which may be near it; whilst a small particle even, taking fire upon the skin, makes the worst variety of burn, and risks setting the clothing on fire. It should always be kept in water, and when not in use, in a bottle, wholly immersed. When accidentally thrown from the plate or dropped from a broken bottle, it may while wet be safely picked up with the fingers and replaced in any vessel of water at hand; but when it has been out of the water long enough to become dry, it should never be touched until it is remoistened, and the hand that touches it should also be wet. In common with all other means of deodorizing, this is very apt to be overdone, particularly since it does not, like most others, become unbearable by its odor, and thus give notice. Ozone in the atmosphere in large proportion is noxious; and even in the proportion which may be obtained by mismanagement of this process, it is capable of producing disagreeable, if not injurious effects. One of the first evidences of its presence in undue proportion is a congestion of the mucous linings of the air, passages, causing that dry, uncomfortable feeling about

the posterior nares and fauces so well known in the commencing stage of a catarrh. It is not supposed to be possible, however, so to mismanage the process above described as to render it dangerous, or even seriously injurious from this cause; neither is it supposed that enough phosphorus vapors could be introduced into the air of apartments to produce phosphorus disease of the bones. Its use as a deodorizing disinfectant should always be regulated with care, and with judgment be adapted to the desired effect. It will then rarely, if ever, be continuously required, no matter in how small quantities the ozone may be liberated; but by intermittent use, say for twelve or twenty-four hours, once or twice a week, will accomplish all that could be expected from it. Judiciously used, therefore, this will be found the most effective, as well as the most simple, neatest, and cleanest of all similar means; whilst the phosphorous acid which it incidentally introduces in very minute proportion into the air, has less odor, and is less irritating and more healthful in its effects than the corresponding products of the other similar agents.

Next to this, in practical efficiency for such special uses, stands chlorine, which, if slowly liberated in the small quantities really required for these uses, is hardly objectionable to the most delicate condition, and certainly never hurtful, whilst it is thoroughly effective and perfectly safe in use. It, however, requires careful and judicious management, and a moderate degree of attention and knowledge to secure these results and avoid overdosing. In use it is less liable to be overdone than the method last mentioned, because the odor is so irritating and disagreeable as to secure a proper correction. It is best liberated from a finely ground mixture of common salt and binoxide of manganese, by means of cold diluted sulphuric acid, and these materials for generating it are put up in packages by many manufacturers, with plain, simple directions for use.* In this form, though not very expensive, it is more so than the phosphorous method, but is safer in its management, whilst the residue from its use is admirably adapted to correct the fetor and destroy the poison of excretions.

About 200 grains of the common salt mixture and half a fluid ounce of the sulphuric acid mixture liberate in the course of twelve or twenty-four hours about fifty cubic inches of chlorine, giving it off pretty rapidly for the first two or three hours, and very slowly afterwards.

Now, if these materials be mixed in the bed-pans or close-stools of a chamber or ward, and be allowed to stand until these vessels come to be used for receiving the excretions; the air of the apartment, the neighborhood of the bed, the vessel itself, and, finally and most important of all, especially in connexion with some late views in regard to the propagation of cholera by or from the dejections, these latter are all thoroughly deodorized and disinfected. This residue, thus susceptible of being so efficiently utilized, holds a considerable quantity of chlorine in solution; but besides this, it contains the sulphate of the protoxide of manganese, which results from the process by which the chlorine is liberated; and this, and the sulphate of soda and the excess of sulphuric acid used, happen all to be very effective disinfectants. The force with which the dejections are discharged into the vessels will not be sufficient to stir up the thick residue (which should have been previously spread or rinsed round over the bottom of the vessel), and therefore the stirring should be done with a short stick before the contents are thrown into the cesspool or sewer pipe; and then, when the vessel and stick are rinsed out and returned to their place, a new portion, or, if the dejections are frequent and small, half a portion, is to be at once mixed in the vessel, using this same stick to stir the mixture with, and leaving it in the vessel until the moment the next dejection occurs. It is then taken out by the patient or attendant, and held till required for that occasion. Some such management in the case of cholera would most thoroughly disinfect the dejections, and probably disarm them of all hurtful tendency, and at the same time keep the cesspools and sewer pipes in an improved condition, since the more frequent the dejections the more frequently would these latter receive the chlorine residues. And, in hospital practice, the more active the disease (cholera for example) might be the more active would be the disinfection, both of the atmosphere of the ward, and of the sewers, waste-pipes, etc. When to be used in this way, on the large scale, the common salt mixture or brown powder should be dispensed to a ward in tin cans, containing say five pounds each, with a little tin ladle adjusted to hold between 195 and 200 grains when filled and struck off level with the edge by means of a spatula or other contrivance used to fill the ladle with; and the sulphuric acid mixture would be dispensed in bottles holding say half a gallon, and accompanied by a small graduated measure or other means of measuring half a fluid ounce. In this way the expense of the plan is very much reduced and the application facilitated and extended, since in large quantities the common salt mixtrue would not cost over thirty cents per pound, including the tin can; and the sulphuric acid mixture not over eight cents per pound, exclusive of the bottle.

Bromine is an excellent disinfectant, and evaporates spontaneously and so rapidly that the simple removing the stopper from a narrow-necked bottle of it in an apartment will soon deodorize the atmosphere, and if the room be warm will become irritant. Like nitrous and sulphurous acids, however, it is very difficult to manage without becoming either inefficient or irritating, whilst it is an expensive and corrosive liquid, so volatile and irritant that an ounce of it accidentally spilled in a chamber would render the air dangerous to life. Like chlorine, iodine, etc., its activity as a deodorizing disinfectant depends upon its union with the hydrogen of the watery vapor of the atmosphere to produce hydrobromic acid, setting the oxygen of the water free in the form of ozone probably.

Chlorinated lime, or, as it is commonly miscalled, chloride of lime, and creasote and carbolic acid, also partake somewhat of the character of gaseous disinfectants or deodorizers, or at least occupy the intermediate

* This, the best method of liberating chlorine without heat, is that of the German chemist Wiggers, and his formula is as follows (Fresenius, Qual. Analysis, Eng. Ed., 1859, p. 28):—"Mix 18 parts of finely ground common salt with 15 parts of *finely pulverized* good binoxide of manganese; put the mixture in a flask, and pour a *completely cooled* mixture of 45 parts of concentrated sulphuric acid and 21 parts of water upon it, and shake the flask; a uniform and continuous evolution of chlorine gas will soon begin, which when slackening may be easily increased again by a *gentle* heat."

This excellent method was adapted to disinfectant uses in hospitals, with directions for the preparation of the materials, and for use, by the writer of this paper, some years ago, for army use; and throughout the war it has been very largely used. Through this large use it has now become an article of common trade, and is doubtless easily accessible, in all the larger cities at least. There is neither secresy, complexity, nor other difficulty in connexion with it. Any tiro can prepare it from the very beginning. The materials are made and sold by most manufacturers, put up after the plan used for the army, as follows: A large pasteboard box contains in one end a pasteboard drawer, in which are placed 130 packages, each containing about 195 to 200 grains of the common salt mixture. The remainder of the box is occupied by a strong half-gallon bottle, containing the sulphuric acid in due proportion to the number of powders. The bottle and box both bear labels explaining the composition and mode of preparing the contents, with simple directions for use. Besides this, the powder and acid mixture are both supplied in bulk by manufacturers for use in hospitals, etc.

ground, partaking of the nature of both gaseous and solid disinfectants, and are all available and effective for many special purposes. Creasote and carbolic acid, as well as the coal-tar from which the latter is separated, are all powerfully antiseptic, and possess the singular property, not only of arresting the putrefactive process, but also of preventing its recurrence, and of destroying the lower orders of living beings which belong to or result from these fermentations. So long as it remains in the pabulum it seems to defend it against all attacks of the nature here considered; but it so happens that it is itself easily decomposed through reactions of a purely chemical character, and its effects are thus somewhat limited.

The creasote of the present day is nearly, if not all of it, a mere impure form of carbolic acid; and as it is equally available with the latter for all these purposes, and cheaper, as well as more generally accessible, it is perhaps best adapted to the special uses now to be briefly noticed. Common commercial creasote is soluble in about the proportion of one fluid drachm to ten fluid ounces of water, by shaking them together in a bottle. But a better solution for burns and scalds, as well as for disinfectant purposes, is one fluid drachm (or a teaspoonful) to a pint of water. Such a solution made in quantity does not cost over one cent per pint, and is particularly applicable to hospital uses. This is the Aqua Creasoti or creasote water of the U. S. Pharmacopœia, which should always be at hand where burns and scalds are liable to occur. For dressings and many other of the uses to which it is specially applicable, it may be still further diluted at the time of application. As an occasional wash to unhealthy sores; as a dressing (out of contact if the surface be irritable) to suppurating injuries, particularly in warm weather; as an addition to the rinsing water for sponges, bandages, oiled cloths, napkins, clothing, etc., which have been or are to be used about sores, etc.; as a wash to sponge off the top of bedside tables, chairs, etc.; and, in short, for profuse use in general about sick or bedridden persons and their appurtenances and dejecta, it is one of the most effective agents yet known, and has the great advantages of simplicity, safety, cheapness, and easy accessibility. In common with all other agents, however, it requires intermissions in use, and, after a time, may with advantage be substituted by agents far inferior to it in antiseptic power. Besides, it has a most persistent, strong, and disagreeable odor, which often, though tolerable at first, becomes so offensive as to be injurious. It is hence better adapted to hospital than to private uses, except where in the latter cases the odor to be corrected and prevented is worse than that of the agent, as, for example, in many cancerous diseases.

Permanganates in solution are very efficient antiseptics. They are not volatile, and therefore odorless and antiseptic only; that is, they do not at all affect existing effluvia in the air, except as the effluvia are brought in contact with the solution. As washes and as dressings for sores, they are, as commonly prepared, more irritant than creasote water; whilst for the purposes of disinfecting sponges, bandages, etc., they are not applicable. For injections, as in cancerous disease of the uterus, they are, when free from caustic alkalies, specially well adapted, and frequently odors may by their use be prevented at their source, which have rendered chambers, or even entire dwelling-houses, offensive. Although safe, and of easy application, the solution requires careful adjustment to each case when used as injections or as topical applications, to avoid caustic or over-stimulating effects; and these solutions must be kept carefully out of contact with organic matter, since they are easily and rapidly decomposed thereby.

The permanganates are complex compounds, the purity of which is important, and not easily judged of by appearance, whilst they are besides expensive, and not generally accessible.

Solutions of sulphite and hyposulphite of soda; of the chlorides of zinc and iron; of both the sulphates of iron; of the nitrates of lead, zinc, and iron; and, indeed, of a very large number of other chemical substances, are all efficient antiseptics or disinfectants, and may each be used as specially adapted, or when specially accessible, to some purposes or conditions. All fulfil the prominent indications of most conditions, but not in like degree, nor with equal convenience in all.

The same may be said of the various patented and self-lauded powders and liquids, all of which are more or less complex compounds of the well known agents referred to in this paper, mixed with absorbent powders, and generally managed so as to fulfil the first and prominent indication to their use—namely, to make money. The well educated physician, acquainted with proper authorities, can no more be satisfied with a single article or compound to subserve all his purposes as a disinfectant, than he can with a single drug or a single prescription with which to treat all his conditions of disease; and patents and patented articles in the medical science and art are but clumsy, slovenly, undignified, illiberal substitutes for knowledge, which involve concealment and deception, and very often mask active and injurious ignorance.

One remark deducible from the character of the processes involved in the necessity to disinfect, may be useful as applicable to all means of special disinfection—namely, that the agents should be occasionally changed or intermitted. For example, a suppurating surface may be so long dressed with creasote water that, although one particular class of reactions is prevented, those of some other class may be called into activity or fostered, and such may have a like tendency to interfere with the reparative processes of nature. This is but another application of that well known experience in surgery which indicates occasional changes in the character of dressings, no matter how simple or effective they may be at first. Again, a chamber or hospital ward may be much more easily rendered injurious to the inmates by the uninterrupted use, month after month, of any given gaseous disinfectant or deodorizer, even the very best than if an occasional change or intermission be made.

We now come to the prominent object of this paper—namely, to endeavor to show, in view of an apprehended invasion of Epidemic Cholera, that there are, within easy reach and in great abundance, two simple agents which are as thoroughly, as promptly, and as surely disinfectant, for general uses, as the nature of the infecting agencies will admit of in the present state of knowledge; and that, by the exercise of a reasonable amount of skill, judgment, and forethought, on the part of the medical profession and the educated classes of the community, these agents may be made eminently useful, and all-sufficient as adjuncts to the greatest attainable cleanliness. In the two common substances, charcoal and lime, may be found agents which, for general disinfectant purposes on the large scale, leave little to be desired; since, used together or alternately, they fulfil more of the indications, and do it better, than any other simple substances. No new evidence of this can or need be adduced, since to collect and epitomize the knowledge upon the practical use and value of these agents as disinfectants would far exceed the limits of this paper. The tendency is, however, so great to overlook simple agencies which lie at our doors, and to forget the accumulations of knowledge which have lost the charm of novelty, as to justify, if not to demand, a re-

view of a few of the prominent qualities upon which the utility of these agents depend, with a view of recalling attention to them at the present time of need.

Charcoal, the more freshly made the better, absorbs, under ordinary circumstances, say fifteen or twenty times its own volume of all the hurtful vapors and gases eliminated in the putrefactive process, and attracts with much promptitude such vapors from the atmosphere around it. All such vapors are held permanently in its pores, and some are decomposed by it into more simple combinations. Partial or even entire saturation with one gas, does not prevent the absorption to a very considerable extent of others; and these absorptions and decompositions by the charcoal go on for two or three weeks, and in the case of some gases longer. Upon this absorption, condensation, and decomposition of gases and vapors, and upon its antiseptic properties of preventing and arresting the putrefactive process, which must precede the development of the lower orders of organic life, and the elimination of noxious effluvia, does charcoal mainly, but not entirely, depend for its efficacy as a disinfectant; and no substance, whether simple or compound, rests upon a better foundation or covers a broader ground. The conditions adapted to its maximum efficacy are its either being freshly made or well kept, and being in a state of coarse powder, and these for obvious reasons; and yet the fine and comparatively worthless residue from kilns and receptacles where it is kept in large quantities is very effective as a disinfectant. An ordinary house-pa lful of this thrown over the surface of the contents of a privy sink or cesspool once a week, or even once in two weeks, especially if alternated with l me, will first, by covering the surface, lessen the atmospheric contact necessary to carry on the processes by which effluvia are produced; second, by extracting moisture from the surface with which it is in immediate contact, it will form a crust in which both the chemical and vital processes are obstructed, and which crust partially seals up the masses beneath, allowing the fluid portions to drain off undecomposed into the earth; third, by forming a filter upon the surface, through which all emanations from below must pass before they can become noxious, and thus filter them out; and fourth, by forming a partition between the fermenting mass below and the new accessions from above, and by absorbing and fixing the latter, it will tend to prevent extension of the proces-, and allow the masses below to be smothered out and exhausted. The applicability illustrated in this single example of its action and uses can be easily extended and adapted by common sense to the various other general purposes for which such agencies are required. Charcoal is produced all over the world, and is easily and cheaply obtained in sufficient quantities almost everywhere; and almost any mill, however crude and simple, will grind it rapidly into the coarse powder most available for disinfectant purposes.

Lime, ordinary qu cklime, produces mechanical and chemical results equal, if not superior, to those of charcoal, but of a character so different as to render a judicious combination of the two better than either alone. It has been shown that the primary character of all the putrefactive processes is one of oxidation, and that the atmosphere as a source of oxygen, under certain conditions of moisture and warmth, is indispensable to this particular oxidation. The results of th s oxidation are a set of oxides, liquid and gase us, generally of either an acid or an oily nature, and to these are superadded the lower orders of organic life. Now lime is a prompt and active caustic alkaline substance. It combines chemically and greedily with its weight of water, and with sixteen hundred times its volume of watery vapor, without losing its solid and apparently dry condition. In absorbing th's large proportion of watery vapor, heat is produced in sufficient amount to cause an active circulation of the atmosphere around the lime; and if the supply of moisture be sufficiently rapid, the heat will be sufficient to entirely destroy the process of fermentation. Again, in absorbing this large proportion of watery vapor from the atmosphere around it, of course all the gases, effluvia, spores, etc., of which this aqueous vapor is the solvent or carrier, are absorbed with it, and subjected to the destructive action of its caustic nature. Now one cubic metre of atmospheric air, equal to, say twenty-eight cubic feet, when saturated with moisture, holds about 140 grains, but occasionally contains as little as 14 grains. The same volume of air contains, under varying conditions, from 7 to 12 grains of carbonic acid, the average being about 9.4 grains; and of organic matters chiefly carried by the aqueous vapor, the variations will range from one-quarter of a grain up to 800 grains, the general average, however, being from 1 to 1.5 grains. The other gases and vapors are in much smaller proportion, and besides, are supposed to be less noxious. An ordinary dwelling-house apartment contains about one hundred times this volume of air, and will therefore contain an average of say 3,500 grains of water and 940 grains of carbonic acid, and 150 to 200 grains of organic matter. Now, to deprive this volume of air of one-fourth part of its noxious impurities would be to change it from the greatest ordinary general insalubrity to a healthful condition; and this would be easily accomplished within the practical working capacity of a quarter of a pound of lime within forty-eight hours. The lime not only combines chemically with all acids and acid vapors, as well as with the water that carries them, but it also combines with all oleaginous matters and products, fixing them into permanent solid and generally insoluble combinations, no matter whether the oleaginous matters be rancid or not. As a caustic alkali it, in common with other chemical substances, poisons the pabulum of organic life, and by its slow and difficult solubility it remains in these pabula longer than any of the more soluble chemicals, and thus goes further in effect. Besides this, as a caustic it destroys the delicate cell-walls of organic life, and coagulates their albuminous contents. In the form of coarse powder, either alone or mixed with charcoal, it is thus applicable to many of the uses of a general disinfectant, whilst in the form of whitewash it offers another series of useful applications, scarcely less important and equally simple.

In purifying and disinfecting human habitations, almost everything may be whitewashed in an emergency; and in the application to floors and other wood-work, whether painted or not, and even to articles of furniture, it permeates cracks, fissures, and spongy surfaces, which can be cleansed and purified as well in no other way, whilst it may be washed off from surfaces to which it is not permanently appropriate with the certainty that in once drying on, its office has been performed.

An empty tenement-house or other infected building, once or twice well filled with wood smoke from a fire made in the cellar, and then well whitewashed all over, will probably be as perfectly disinfected as it could be by any other means whatever, and certainly as easily and as cheaply. The smoke carries creasote, charcoal, acetic acid, and carbonic oxide and acid, with aqueous vapor enough to dissolve and diffuse them, and with these penetrates all spaces, even the dark and hidden abodes of the cryptogams otherwise inaccessible. The temperature of the smoke very much aids the laws of diffusion, by which its gases and vapors are rapidly

disseminated equally throughout the whole space and brought in contact with all the surfaces and recesses; and this temperature also increases the carrying capacity of the smoke by which its solution of creasote and carbonaceous matter is firmly held until condensed by contact with the cooler surfaces. Smoke thus has some penetrating and pervading qualities not possessed to the same extent by other gaseous disinfectants. After such smoking a general, thorough whitewashing completes the effective process. From this brief review and illustrations, it may be seen that it would be difficult to conceive of two agencies, as charcoal and lime, which together would better cover the whole ground involved in this subject of general disinfection, or two which are so universally accessible, so easy of application, so safe, so simple, and so cheap. Lime may, like charcoal, be ground fine enough for disinfectant purposes by almost any kind of mill, however crude; but ordinary plaster mills are perhaps best adapted to the work. In the absence of a mill of any kind, it may be reduced to powder by sprinkling upon it from one-fourth to one-half its weight of water. This partially slakes or hydrates the lime, and to a proportionate extent impairs some of its qualities as a disinfectant. But as, in common with charcoal, it possesses these qualities in so great excess over most other agents, it can afford this impairment and still be very effective, even in absorbing aqueous vapor. But besides, when saturated with water or thoroughly slaked, it is still in powder very useful, since its capacity for acid vapors, etc., is rather increased than diminished thereby. It follows from this that as whitewash it has little or no effect upon the aqueous vapor in the air, and its action on the gases which the air contains is here entirely independent of the absorption of the aqueous vapor. But the extended surfaces to which it is usually applied so increase the contact from a given quantity of lime, that it is probable that four ounces of lime spread as whitewash upon the walls of a chamber would abstract more carbonic acid from the air in a given time than a pound of the same lime in powder contained in a shallow box upon the floor. To sum up, therefore, it may be confidently asserted that lime as a powder, to be strewn over dirty, damp places, or upon the surface of the contents of privy sinks and cesspools, or for use in water-closets, garbage receptacles, etc.; in connexion with charcoal or alone; and in the form of whitewash to be spread over broad surfaces, including floors, gutters, alleyways, etc., and especially when this is frequently repeated, is a most efficacious and important disinfectant, if not the best of all such.

Freshly prepared lime and charcoal in the proportion of about two parts lime and one part charcoal, ground together into coarse powder, and the powder at once securely packed in barrels for use, could probably be obtained for about three dollars per barrel in large quantities; and such a powder would fulfil all the indications to the use of both agents, and would constitute as good a general disinfectant for all the various uses in the form of dry powder, as could be produced in the present state of knowledge; and if the community would accept the accumulated evidence of character, and settle down upon the use of this which everybody could prepare and sell cheaply as a common merchandise, the greatest general good attainable would be likely to result. Such a compound might be appropriately called "Calx Disinfecting Powder," or briefly, "Calx Powder," and be sold by pharmaceutists in arbitrary packages or by the pound at a low charge. This, with the common "chloride of lime," would then be generally available, and would subserve all the popular ends.

In many cases common recently calcined plaster of Paris, or "plaster," as it is technically called, forms a good disinfectant, acting however wholly as an absorbent. Mixed with the contents, or with the surface contents of privy sinks, cesspools, etc., it solidifies them by abstracting the water, and "setting" as it is termed—thus in a measure arresting the processes, and fixing the effluvia. Mixed quickly into a thin paste and quickly applied to cracks and crevices about the covers of cesspools and other sources of offensive effluvia; and applied thus as a cement or plaster for sealing up sinks, cesspools, etc., either after having been emptied, or to secure them against doing harm during weather, or under circumstances which prevent their being emptied or cleaned, this often subserves very useful and important purposes, setting as it does into a hard cement.

BROOKLYN, April 25, 1866.

PERFORATING DISEASE OF THE FOOT.

By HENRY G. PIFFARD, M.D.

LATE HOUSE SURGEON TO BELLEVUE HOSPITAL, N. Y.

I DESIRE to draw the attention of the profession to a disease to which I can find no reference in our English or American literature. In France there have been a few cases reported, and a summary of what is known upon the subject has been given to the profession in a brochure by A. Delsol.

I will first quote a case or two from the brochure mentioned, and then give the author's views as to their nature, pathology, and treatment; hoping that our American surgeons may have met with other examples, the particulars of which may throw some light upon this curious malady.

J. B., aged 55 years, good constitution, entered the Beaujon Hospital Sept. 19, 1863. Eight months before admission an ulcer appeared on the sole of his right foot, over the prominence of the first metatarsal bone, caused, he thought, by a peg projecting from his boot. To this various dressings were applied without success, until at length, unable to walk, he entered the hospital.

The foot presented the following appearances: At the ball of the great toe there was an ulcer about half an inch in diameter, surrounded by a wall of epidermis, very much thickened and with edges clean cut as if punched out. The bottom of the ulcer was composed of a blackish and fissured semi-fluid substance, permitting a view of a reddish villous tissue beneath, from which a slight sero-purulent secretion issued. The probe passed readily through this tissue, reaching the head of the metatarsal bone, which was found to be carious. The foot exhaled a strong and peculiar odor.

In spite of treatment, the foot became worse, phlegmonous inflammation set in, and abscesses formed at different points, with infiltration of pus among the tendons; so that, despairing of cure, amputation of the leg through the middle third was performed on the 26th of November. The patient succumbed on the tenth day.

Autopsy.—The various viscera were free from organic disease, with the exception of small points of calcification in the aorta. There were also very large fibrinous clots in the right cavities of the heart, extending into the pulmonary artery, together with hypostatic congestion of the lungs. An examination of the foot revealed extensive purulent infiltration, with sinuses leading down to the metatarsal bones. There was also *calcification* of the posterior tibial, and external and internal plantar arteries.

J. S., aged 50 years, entered the Beaujon Hospital on the 4th Dec., 1863, with a disease similar to that of the last

patient, but affecting both feet. The disease had appeared four months previously, on the left foot; an ulcer forming on the sole of the foot near the head of the fifth metatarsal bone. Two weeks later, an ulcer appeared on right foot near the great toe. These healed in about six weeks. The patient resumed his occupation, but was soon compelled to desist in consequence of a return of the affection. From that time until his entrance into the hospital (about two months), the ulcers showed no tendency to heal.

They presented appearances similar to those in the first patient, except that the disease was not so far advanced, insomuch as, although the ligaments of the metatarso-phalangeal articulation were exposed, they were not perforated, and there was no caries of the bones. Poultices were ordered Dec. 10th; under the influence of the cataplasms, the thickened epidermis was softened and easily detached, and injections of tr. iodine and water were employed. Dec. 20.—The ulcer of the right foot is healed; that of the left improving.

January 17, 1864, the ulcer of the left foot has been healed some days. The patient can walk without inconvenience. Discharged.

The other cases cited, about a dozen in number, four of which were observed by Dr. Delsol, presented a remarkable uniformity of course; usually there first appeared at the root of one of the toes a thickening of the epidermis like a corn, but more extensive and painless. In the centre of this an ulcer appeared, penetrating the tissues, until the periosteum was reached, and the bone denuded. If appropriate treatment were commenced at this stage, the ulcers generally healed in a few weeks; but if the disease pursued its course unchecked, the ulcer penetrated the joint, destroying the articulation; and new ulcers and fistulæ formed, leading down to the other metatarsal bones. Some of the patients finally submitted to amputation of the affected member.

Three cases afforded an opportunity for dissection of the parts—two after death, and one after amputation. In these cases, besides the appearances presented by the ulcers, there was one constant lesion, namely: calific degeneration of the arteries of the foot. The ages of the patients were respectively forty, fifty-five, and fifty-nine years. This coincidence is *strange*, but the Doctor neglects to state whether an examination was made of the arteries of the upper extremities, or of the brain; and if so, what was the result. In two or three cases there were points of commencing gangrene.

The nature of the disease is obscure. Is it a purely local disease, depending upon a local condition of the nutrient vessels; or is it another form of senile gangrene to which all are liable in whom the arteries generally have undergone atheromatous changes; or is it a manifestation of syphilis? The two first questions I cannot answer; respecting the last, it is stated that anti-syphilitic treatment was tried in several cases without benefit.

The treatment adopted in most of the cases that terminated favorably, consisted in rest, poultices to remove the thickened epidermis, and injections of tr. iodine and water.

Monument to Commemorate the Discovery of the Anæsthetic Properties of Ether.—A wealthy citizen of Boston has placed a liberal sum of money at the disposal of Messrs. Ware & Van Brunt, architects, to commemorate the great medical discovery of modern times. It is intended as an expression of thanksgiving, as it were, for the great alleviation which it has brought to human suffering, and the monument which these gentlemen have designed is intended to convey this in a poetic form. The monument is to stand in the public garden facing Marlborough street.

REMARKS ON DISINFECTANTS.

By CHARLES A LEE, M.D.

In a Letter to Dr. Marsden, of Quebec.

The only true disenfectants are perfect ventilation and cleanliness. No widespread epidemic can exist without localizing causes of disease. These localizing causes are overcrowding, deficient sewerage and drainage, organic matters, whether vegetable or animal, liable to decomposition, great humidity, impurity of drinking-water, want of personal cleanliness; in short, whatever contaminates the air, water, or food. These must be zealously guarded against at all times, especially when there is danger from any infectious or contagious disease. It is the duty of all communities to secure, as far as possible, personal, domestic, and civic cleanliness and purification, by the prevention or removal of all these local causes of disease. If this be done, no special disinfectants will be needed. Great injury may result from placing too great reliance upon them.

It is necessary, also, to remember that an offensive odor and a *virus*, a poisonous miasm, have no necessary relation. The poison of malaria, for example, is not accompanied by any offensive smell; while, on the other hand, we know that the most offensive odors, as those disengaged from putrefying animal matters, do not themselves necesarily act as poisons. But let the choleraic, or any other specific virus, be introduced in localities where such effluvia exist; then these latter furnish the pabula for their indefinite multiplication and extension. They furnish the fermenting material or mass on which the fermenting virus of disease operates.

It is a necessary inference from this fact that chemical or other agents which are capable of removing the offensive odors resulting from animal and vegetable decomposition, may be inert as regards the poisonous miasm or virus on which infectious diseases, as cholera, depend for their germinating principle. A *deodorizing* agent is not therefore necessarily a *true disinfectant.* In a general sense, a *disinfectant* then may be considered as an agent for removing the causes of infection. It matters not, practically, whether it destroys the specific *virus* of disease, by a chemical, decomposing, oxidizing, or deoxidizing action; or renders it inert by fixation, as by the use of an absorbent; or by arresting those putrefactive changes and chemical actions, by which the poison is rendered capable of multiplication and extension. Cholera is manifestly self-generating, under certain favoring conditions, as the presence of organic matter in the atmosphere, excess of moisture, a certain temperature, etc.; and if these conditions can be prevented or obviated, the choleraic cell, germ, or virus, will not fructify, and the disease will become extinct, or not extend, for want of its proper *nidus or pabulum. It cannot be denied that we have such agents, and, therefore, that cholera is, to some extent at least, under our control.* If these views are correct, then at least three different classes of agents may be included under the general term *disinfectant;* but the term, as I have already intimated, is not a good one, for it does not express the exact or entire truth. Some of our disinfecting compounds probably act in all of these different ways; and it is owing to this circumstance that they are more efficient and reliable than any single substance. Several of the more important of these will be mentioned hereafter. Disinfectants, then, naturally arrange themselves under three different heads or classes: viz.

1. Chemical disinfectants. 2. Absorbents. 3. Antiseptics.

We have, I think, sufficient evidence to render it highly probable, at least, that *chlorine gas* and the *alkaline chlorides of lime and soda; the mineral acids*, and their gases; *charcoal, quicklime, caustic alkalies*, the *manganates and permanganates, the sulphites and hypersulphites*, etc., and positively *dry heat* above 250° F., may be called *true disinfectants*, as they have the power of destroying the infectious virus or agent. I know this has been denied; but you will observe that the evidence on which the denial is founded is entirely of a *negative* character, while the affirmative seems to be supported by positive facts. We may admit that they have sometimes, and even frequently failed, just as quarantine has failed; but in these cases it would not be difficult to show that the failure is not due to any want of efficacy in the measures employed, but to the very partial and imperfect manner in which they have been carried out. Any proposition whatever in medicine, however absurd, can be proved in the same way, and no one knows better than yourself the numerous sources of fallacy in reasoning of this kind. By the same line of argument precisely, we can prove the non-contagiousness of measles, scarlatina, yellow fever, and small-pox, and even the inefficacy of vaccine as a preventive of the latter. Here, as in all the practical applications of our art, we must aim to imitate, as far and as clearly as possible, the sanitary processes of nature, whose great purifying and hygienic operations are chiefly *oxidation, diffusion, and dilution.* All these we can imitate to a certain extent; but there are others, as temperature, winds, the fall of rain, the electrical, magnetic, and hygrometric conditions of the atmosphere, etc., which are beyond our reach. *Thorough ventilation* is doubtless the most important hygienic and disinfectant agency we can command, and subsidiary to it is *chemical action;* which, even at the best, must be partial and imperfect, and consequently uncertain. Doubtless, if it can be brought directly to bear upon the poison of any infectious disease, it will destroy it; the difficulty is how to effect this. The most effectual means of purifying the air, independent of ventilation and the removal of organic matters, is the evolution of certain gases, such as chlorine, hyponitrous, nitrous, and sulphurous: of these the nitrous acid is believed to be the most powerful; but it is useful, and perhaps expedient, to employ all three alternately, or even together. They are never to be regarded in any other light, however, than as auxiliary to ventilation, etc.; if they supersede them, as above stated, they would prove more injurious than beneficial. *Chlorine* stands unrivalled, however, for its power of destroying putrid odors and checking putrefaction; although its irritating and irrespirable properties render it very objectionable and even inadmissible in large quantity in inhabited dwellings and wards of hospitals. It acts instantly on all organic vapors and gases, partly by oxidation, and partly by its affinity for hydrogen; decomposing readily sulphuretted hydrogen, ammonia, hydrosulphuret of ammonia, phosphuretted hydrogen, and other fetid or offensive effluvia and vapors; and as the virus of infection must unquestionably be some animal organic compound, analogy must lead us to believe that chlorine will decompose it as readily as other bodies of a similar kind. That it rapidly destroys organic matter is evident from its power in bleaching organic pigments, and destroying organic odors. In all the experiments made with chlorine, etc., for the arrest of cholera in former epidemics of this disease in Russia, Austria, Hungary, Great Britain, France, etc., it is worthy of note that in none of the trials was chlorine or any other disinfectant added to the stools, but they were merely diffused in the air. Under such circumstances a failure was, of course, to be expected. No fact has been more fully established by careful observations, made in every quarter of the world, during the last forty years, than the contagious nature of cholera evacuations; and that, as Greenhow of London remarks, "an atmosphere impregnated with the products of *fermenting excrements*, is at once the most obvious and most constant concomitant of cholera;" and Dr. E. Harris, late Health Physician of New York, states that he "has seen abundant evidence of the infectious agency of the rice-water evacuations;" and that in ten different epidemics of cholera at quarantine, "the disease was introduced by cholera patients from ships, when there was no cholera upon the Atlantic coast." If, then, the infection resides in, or is generated from cholera stools, to these should disinfectants be immediately added, or rather placed in the vessels receiving the discharges; and we should hardly expect any such agents to be entirely effectual when the wards of a hospital, private dwellings, or the atmosphere of any given locality, is impregnated with the cholera poison. But we are not without considerable proof that chlorine fumigations may be effectual in preventing the spread of cholera in a hospital. Observations made during 1854 in the different general hospitals of Paris, show that the greatest number of cases of cholera occurred within those wards into which the greatest number of cholera patients were brought from without, except in M. Monat's wards, where chlorine fumigations were used; and this surgeon states that "there was almost complete immunity from cholera contagion in his wards from the moment of the permanent instituting of chlorine fumigations in them." At the hospital Gros-Caillou, where many cholera patients were admitted, and where the dejections and vomited matters were disinfected, not a single case of the disease occurred. Numerous instances of a similar kind could be given, but it is unnecessary. I may, however, refer you to the very decisive experiments in the two large prisons at Munich, in one of which very strict and energetic measures were adopted, during the prevalence of the disease, to disinfect the discharges of all the prisoners and inmates by chloride of lime, etc., and the result was that only one case occurred among 500 inmates; while in the other institution, in which no means whatever were adopted of disinfecting the discharges, fifteen per cent. of the inmates were attacked. The preventive measures employed were in accordance with the German theory that the cholera poison results from the decomposition and fermentation of cholera discharges, under an elevation of temperature of at least 50° Fahrenheit. In regard to the *mode of employment:* One pound of *chloride of lime*, or *chloride of soda*, may be added to three gallons of water, of which a few ounces should be placed in the vessel receiving the evacuations, whether by vomiting or stool. *Chlorine gas* may be given off from chloride of lime, or of soda, slowly, by moistening them with water, and placing them in shallow vessels; or, when desirable, may be rapidly developed by pouring four parts by weight of strong hydrochloric acid on one part of powdered binoxide of manganese; or by mixing four parts of common salt and one part binoxide of manganese with two parts, by weight, of sulphuric acid and two of water, and heat gently; or, a better plan still, is to take two tablespoonfuls of common salt, two teaspoonfuls of red lead, half a wine-glassful of sulphuric acid, and a quart of water; mix the salt and lead with the water, stir well, and add the sulphuric acid gradually. Chlorine is evolved and absorbed by teh water, from which it is slowly given out; or it may be evolved more rapidly into the atmosphere by the application of heat. It may be kept in a jar or stoppered bottle, left open as occasion may require.

Nitrous Acid.—The action of nitrous acid on organic matter is very great and rapid; removing the smell of the dead-house sooner than any other gas. The principal objection to its use is its irritating properties when inhaled; therefore when used, the rooms should either be cleared, or it should be disengaged slowly, which may be done by diluting the nitric acid employed. The ordinary method is, to place nitrate of potash in sulphuric acid; or more simply, by putting a bit of copper in nitric acid and a little water.

Sulphurous Acid.—This is most easily evolved by burning sulphur. This, like nitrous acid, acts powerfully on organic matter by deoxidation; completely destroying miasms and animal contagions. It is, however, like the former, irrespirable, unless in very minute quantities. Where these gases are employed, it is nevertheless necessary to add chloride of lime, or some other good disinfectant, to the evacuations.

These agents are believed to be not only antiseptic and deodorizant, but to break up and destroy decomposing matters and the matter of contagion by converting them into their ultimate gaseous products, and hence may be called *true disinfectants.* If they merely prevented or retarded putrefaction, they would, like *carbolic acid* and its compounds, be simply antiseptic. The chloride of soda has one advantage over chloride of lime, viz. that by the process of disinfection it becomes chloride of sodium, which is not a deliquescent salt; whereas the chloride of calcium, generated by chloride of lime, attracts water from the atmosphere, and thereby furnishes one of the conditions (viz. moisture) necessary to the putrefactive process. Still, for mere disinfection, chloride of lime serves equally well. In the Crimean war, quicklime, chloride of lime, and charcoal, were the chief disinfectants used.

Charcoal.—This substance is supposed by many to deserve to rank among the true disinfectants. Presenting as it does an immense surface to the air, one cubic inch of it equalling one hundred square feet of surface, it separates and absorbs oxygen from the atmosphere, and oxydizes rapidly almost every substance capable of it. From its great power in this respect, it must virtually and actually destroy all animal contagions and organic emanations in disease.

Thus, *charcoal-filters* are extensively and most successfully employed in England, to disinfect the air from sewers and cesspools, etc., having a strong affinity for all the compounds of hydrogen. To a certain extent, charcoal acts on the principle of *fixation* and as an *antiseptic*, absorbing about fifteen per cent. of its own weight of gases and moisture from the atmosphere in twenty-four hours; also ninety per cent. of its own volume of ammonia, and fifty-five times its volume of sulphuretted hydrogen gas; proving alike deodorant and disinfectant, from its property of correcting all kinds of putrefaction. Besides, it is one of the cheapest articles that can be used for this purpose. The British "Sanitary Commission" in the Crimea recommended as a powerful disinfectant, a mixture of one part peat charcoal finely ground, with one of quicklime and four parts of sand or gravel.

A highly useful disinfectant ("*Thompson's Disinfectant*") has been lately introduced, consisting of fresh and finely ground *charcoal, quicklime, ashes,* and *salt,* in the proportion of six parts charcoal to two of lime, and smaller amounts of the other ingredients. This acts as a powerful, and perhaps true disinfectant, by means of the chlorine which is slowly given off, as well as by the oxydizing power of the lime and charcoal; and while nearly or quite equal to chloride of lime, it may be furnished at half the cost or less, and is free from the objection of possessing highly irritant properties on inhalation. This compound is also highly absorbent and antiseptic. For disinfecting sewers, drains, privies, cesspools, etc., it can be confidently recommended.

Quicklime, from its highly oxydizing power, has the property of rapidly destroying all organic substances, especially those of animal origin, and hence proves disinfectant. It unites with great avidity, with sulphuretted and phosphuretted effluvia and moisture, furnishing a chemical base for many acids; setting free, however, ammoniacal gases. It is also one of the best antiseptics and deodorizers. For these purposes, it should be used dry and unslaked; but where it is employed for combining with carbonic acid gas, it must of course be mixed with water, or reduced to a creamy hydrate. Distributed in shallow vessels, it is thus most usefully employed in overcrowded wards, barracks, prisons, or tenement houses, etc. As a temporary expedient, it answers an excellent purpose sprinkled freely in sewers, drains, gutters, privies, cesspools, etc.

The second class of disinfectants includes those agents which act chiefly by absorption, as earth, fuller's earth, porous clay, sulphate of lime, etc., and which exert no strong chemical action.

The sulphate of lime and *sulphite of lime*, etc., thus by *fixation* answer the purpose of disinfectants. All ammoniacal and sulphuretted effluvia, as well as the hydrogenous gases, are readily absorbed by them, thus serving as deodorizers. They also serve as useful vehicles for some of the more powerful and expensive antiseptics, as *carbolic acid, charcoal,* the chlorides, hyposulphites, and metallic salts. For example, "McDougall's disinfectant," or "powder," consists of carbolic acid, sulphite of lime, magnesia, and porous silicate of alumina; the "disinfecting powder of Messrs. Corné & Demeaux" consists of ninety-four per cent. finely ground gypsum, and five or six per cent. of the heavy oil of coal tar." The smell, however, of carbolic acid renders it objectionable in the wards of hospitals and in inhabited dwellings.

The third class of disinfectants, so-called, includes the *metallic salts;* these are useful deodorizers, reacting on sulphuretted hydrogen and the hydrosulphurets; forming insoluble, inodorous, metallic sulphurets; uniting also with animal matters, and checking putrefaction. They may very properly be said to act by *fixation*, and thus prove indirectly disinfectant.

The most important of these are the following, viz:—

1. "*Ledoyen's Disinfecting Fluid*"—a solution of nitrate of lead in the proportion of one drachm of the salt to a fluid ounce of water. But the acetate or subacetate of lead will answer equally as well as the nitrate.

2. "*Burnett's Disinfecting Liquid*"—a solution of chloride of zinc. This has very little power of decomposing the compounds of hydrogen.

3. "*Ellerman's Deodorizing Fluid*"—a solution of sulphate of copper.

4. *The Salts of Iron,* especially the protosulphate and the proto-chloride, are among the most useful articles of this class; as the former is also one of the cheapest. Their control over ammoniacal, sulphuretted, and other noxious effluvia is very prompt and striking. As they are very soluble and convenient, they may be advantageously used in many ways separately, or in combination with other deodorizing materials, especially for placing in vessels for receiving choleraic evacuations by vomiting or stool. Also to add to privies, cesspools, etc. "*The Ridgewood Disinfectant*" consists of *proto-chloride of iron, carbolic acid,* and *fuller's earth.*

5. *The Permanganate of Potassa.*—This is regarded by many as the most efficient salt of this class, and doubtless has greater chemical power than any of the above mentioned. It is consequently a more

decided disinfectant and deodorizer, being more expensive it is, however, less used. It is very soluble and convenient of application, especially for t pical purposes in hospital surgical practice. To purify contaminated apartments, evaporating cloths saturated with a strong solution o' the permanganate, may be employed. Our army surgeons, who have used it during the late war, all bear strong testimony to its powerful oxydizing and antisept'c effects upon organic and putrescent matters; being in fact one of the most sensitive tests of the presence of organic matter. One of its most useful applications is, the purification of water from organic matter, dropping minute quantities of it into the water, *until the tinge of the permanganate begins to appear.* On shaking well, instant deodorization takes place; and thus water offensive to the smell from the presence of decaying animal and vegetable matters, becomes at once tasteless, colorless, and palatable, while the amount of permanganate, necessary for this purpose, only renders the water therapeutically tonic, and wholly unobjectionable.

"*Conby's Disinfectant*," "*Darby's Fluid*," etc., and the different preparations of "*Ozonized Water*," are all solutions of permanganates.

6. *Iodine and Bromine, and their Compounds.*—These are all powerfully antiseptic, whether used topically or diffusively. Their strong fumes being irritating and irrespirable, they are to be very cautiously used in this form. For fumigating wards of hospitals, etc., vessels containing a solution of pure bromine, or the bromide of potassa, may be distributed at different points. It does not come within the objects of this letter to speak of their surgical uses and applications.

7. *Coal-tar Compounds—Carbolates*.—These substances have come into very extensive use recently, as antiseptics as well as deodorizers. Their offensive smell renders them objectionable, to some extent, in inhabited dwellings, wards of hospitals, etc.; but they are invaluable for disinfecting sewers, drains, privies, cesspools, stables, etc. *Coal-tar* is generally obtainable at gas manufactories, being one of the chief refuse materials, and is not expensive. We have no agents, perhaps, which will more speedily arrest the decomposition of organic matters, and remove offensive effluvia, than carbolic acid and its compounds. When used for chamber vessels, close-stools, etc., a very good preparation is made by combining equal parts of *coal-tar*, *alcohol*, and *soft-soap*; a small quantity suffices.

Heat.—It is very fortunate that we have so certain, prompt, and effectual a disinfectant as *dry heat*. It is now more than thirty years since Dr. Henry, of Manchester, England, proved that the infectious matters of diseases may be dissipated or destroyed by a temperature not below 200° F.; and he therefore suggested that infected clothing, goods, etc., may be disinfected on this principle. This has been successfully carried out in numerous instances since, in regard to the infectious virus of scarlatina, plague, typhus, yellow fever, cholera, etc.; and it is found that neither the texture nor color of fine-goods and other articles of clothing is at all injured by a temperature of 250° F. Rooms, ovens, etc., may be easily prepared to be heated by hot air, conducted through pipes, at all the principal ports, where all the suspicious clothing, goods, etc., might be thus readily disinfected.

1. The principal conclusions, then, at which we arrive are, that there are no safe substitutes for free ventilation and cleanliness, whether as regards the wards of hospitals, the rooms of private dwellings, or the streets and lanes, etc., of towns and cities.

2. The compounds of *chlorine* are among the most powerful agents known as true disinfectants, antiseptics, and deodorizers.

3. Solutions of some of the salts of *zinc*, *lead*, *copper*, or *iron*, are perfect deodorizers and antiseptics, and may be placed with advantage in all vessels receiving the evacuations of cholera patients.

4. A compound power of *sulphate of lime*, *powdered charcoal*, *salt*, and *wood-ashes*, is the best article for ordinary use in the destruction and absorption (fixation) of all noxious effluvia and poisonous gases; and may be used with great benefit in streets, gutters, sewers, drains, privies cesspools, stables, water-closets, and wherever organic matter is exposed to decomposition. This is cheaper than any other antiseptic or disinfectant, and equally efficacious. This also answers a good purpose for the deodorization of solid bodies, which are to be covered with it; a mixture of some of the salts of *zinc* or *iron*, mixed with *sulphate of lime* or *saw dust*, answers perhaps equally well, though more expensive. *Equal parts of quicklime and charcoal* also answer for all common purposes of disinfectants.

5. Some of the above substances should be daily added to all sinks, privies, cesspools, water-closets, etc., in places where cholera prevails.

6. To disinfect articles of clothing, goods, etc., which have been exposed to cholera poison, *dry heat above 200° F.* is the only safe and perfect method. Conveniences for carrying out this plan should be in readiness at all our ports, as well as places where cholera prevails.

7. As *ozone* has the power of rapidly converting the products of animal and vegetable decomposition into innocuous compounds, it is an important desideratum to ascertain the best mode of developing this powerful agent in the sick-room, wards of hospitals, etc. Further experiments are needed on this subject. The common method of exposing a piece of phosphorus in a room to be disinfected, is the process generally adopted.

In submitting these remarks on disinfectants, I should do injustice to myself and the cause of science, did I not again caution against placing too much reliance upon them against the introduction or spread of cholera, or any other infectious disease. They are only to be regarded as subsidiary to the great sanitary measures of free ventilation, purification, and cleansing by water, etc., sewerage and draining, etc. No substances liable to putrefaction and decay, must find lodgment in houses, lanes, alleys, streets, workshops, or any other place; and if this were thoroughly done, no disinfectants would of course ever have to be used. There is no doubt that great injury has resulted to the health of both communities and armies from too great confidence being reposed in disinfecting measures. But in large cities, as well as camps and hospitals, it is next to impossible to remove all organic matters so thoroughly or so promptly as to prevent the escape of noxious and offensive effluvia. Hence, disinfectants are a necessity, and probably always will be; and we must try and learn which are the most reliable, and, indeed, if there are any deserving the name.

German Hospital in Newark, N. J.—The Germans in Newark, N. J., are inaugurating measures for the establishment of a hospital in that city for the accommodation of their countrymen.

A Fish Epidemic is reported at Richmond, Va Large numbers of all sizes float on the water, and when taken out appear bloated, and die in a few minutes.

Original Lectures.

ON CHOLERA.

By A. CLARK, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

Lecture IV. Part II.

The Theories in regard to the Origin and Spread of Cholera. (Continued.)

If I were to select from all the published reports the statement which seemed to prove most conclusively the contagious character of cholera, I should take the one I am now about to read to you. The facts are recorded by Baly and Gull (p. 166), and relate to a very large school for poor children in the immediate neighborhood of London, called the Tooting School, from its locality. In winter, in December, 1848, cholera appeared there in unusual severity. It was so violent that the governors of the institution found it necessary to break up the school, and send the children to the parishes whence they came. The result was as follows:—Forty-five of these children were sent to Bellevue House Pauper Asylum, Margate, on 6th and 7th of January. On the 8th one of them died, and immediately several of the inmates who had not been to Tooting were attacked; two died on the 11th and one on the 23d. One hundred and fifty-five of the children were sent to the Royal Free Hospital on the 5th of January. Four of these died between 6th and 8th; five of the attendants were attacked, and two died between the 13th and 20th. Nine died at St. Pancras Workhouse between 6th and 20th January. A few days after their arrival a person residing in another part of the building was attacked and died. Some of the children were temporarily placed in the Park House, Hackney; and four of them died between the 10th and last of the month. A young woman brought from Islington to nurse them was attacked, and died on January 14. One of the children died in a house in Marylebone District, and two in Kensington Workhouse. There the disease did not spread. One of the attendants at the Royal Free Hospital died at Holborn Union Workhouse, and the disease at the same time broke out in that establishment. The cholera was not prevailing in any of these institutions, or indeed in the districts in which they were situated, at the time the infected persons were received, although it was epidemic in other parts of London. It is to be remarked however, that in the Holborn Union one man died of cholera on the 13th, while he who had been with the cholera at the Royal Free Hospital died on the 14th. They fell sick at about the same time, and their beds were opposite and near each other. In these five instances cholera seems to have been carried from one institution to another by the sick. But there were other institutions which received portions of the Tooting children, and were not similarly visited.

Let me give you another narrative that would be selected as proof of the contagious character of cholera. It it reported by Dr. Ohr, of Maryland (*American Journal of Medical Science*, January, 1854), and relates to the prevalence of cholera in the town of Cumberland in the year 1853.

The first case which occurred in Cumberland was in the person of a boatman on the Chesapeake and Ohio Canal, about the middle of July. He had come from Williamsport, where the cholera was raging with considerable violence. He lay out on the "green," and died the next morning. The next case occurred about two weeks later, also imported. The subject was a boatman from Williamsport. He lay sick in a green-grocery kept by a man named Hall; he recovered. On the 6th of August, six or seven days from the time of this boatman's arrival, a little girl living with Hall died. Hall died on the 7th. On the same day a boat-builder named Cooter was taken with the disease, and died in nine hours. He had been at Hall's the day before. Meantime several deaths had occurred in the immediate neighborhood of Hall's grocery. On the 8th, Kennedy and several of his family were attacked. They lived fifty yards from Hall's, and had been there. On the night of the 8th, Hazel Beall, a watchman, was seized; he had been at Hall's. On the 12th Mrs. Beall was attacked; Beall's house was about a mile from Hall's, and near Cooter's. Four of Beall's children were attacked successively. Some of the children were taken to Mrs. Simpkins's, an adjoining house. Mrs. Simpkins and her child died. On the 10th or 11th Mrs. Nelson Beall went to the house of Hazel Beall, who was still living, and assisted in nursing. She was attacked, went home, and died on the 13th. Her husband and two children were attacked, and died on the 19th. Nelson Beall lived about a mile south-east of Hazel Beall, and out of town. No person in the neighborhood of Nelson Beall's entered his house, and none suffered from the disease. On the 18th Sullivan was attacked; he had been a day and night at Hazel Beall's. He lived three-quarters of a mile east of Hall's, and a greater distance south-east from Beall's. His mother, and three children of his brother, were attacked successively. No other person in that neighborhood had the disease except two mulatto girls named Cole, who had assisted in taking care of this family. From the 6th to the 18th a number of deaths occurred along Green street, in which was Hall's grocery; some in the different parts of Mechanic street in which Cooter and Hazel Beall lived. Some in other places, said to have been from cholera morbus. On the 19th there were 13 victims. The town became alarmed; many (3000) fled, and it became impossible to trace the communicable features of the disease further. Hall's grocery was a long low old one-story frame building, the base about three feet below the pavement. It was kept for the retail of cakes, candy, liquors, potatoes, cabbage, codfish, etc. Much of the codfish was rotten; it was a place for boatmen, loafers white and black, and of strong odors. It stood on the corner of Green street, where Will's Creek joins the Potomac, "as favorable a place for the incubation of pestilence as could be desired." The place had been healthy till the 1st of August, though the air had been dry, hot, and stagnant.

Here is a history that certainly countenances the idea of communication from person to person.

The following account is often quoted to enforce the doctrine of contagion. It was written by Dr. Keckerley, and runs thus:—

The Brig Amelia sailed from New York on the 19th October, 1832, bound for New Orleans with over 100 passengers, all but three or four in the steerage. After being at sea six days, cholera broke out in the steerage. The voyage was one of extreme dangers and excitements; and finally the brig was run ashore to save the lives of passengers and crew, on Folly Island, near Charleston, S. C. This was on the 31st of October, six days after the cholera had appeared in the vessel. Twenty-four persons had died and several were still sick. The passengers were landed, and being in great want and distress, relief was sent from Charleston.

A boat's crew of wreckers was sent down to save the vessel and cargo. On their return one of them was attacked with cholera and died in Elliot street. This man "was visited by hundreds of persons," none of

whom had the disease. The boat's crew were ordered back to the island. Two fell sick; and one died on the way down. The wreckers were very intemperate; and the man who died in Elliot street, besides living or being attacked in an insalubrious locality and being intemperate, had slept in wet clothes.

More wreckers were sent down. A guard of eighteen men was set over the infected persons. The guard soon returned to a distant part of the island, dissatisfied and disobedient.

Four negroes were the only persons left on the island. Of these four, three died, two adults and one child. Of the guard, every one except the commanding officer, it was reported, had choleraic symptoms; nine were reported as severely attacked; one died. Of the wreckers, eight died. On the 8th of November the wreck was burned.

On the 10th the nurse who attended the wrecker in Elliot street, the week before, died. After the 17th no more cases were reported, the weather having become remarkably cold. On the 19th the healthy passengers left by another vessel; and though twice wrecked on the voyage, no more cholera appeared among them.

Dr. Keckerley thinks that there is no fact in this narrative favoring the idea of contagion. He says that in Charleston during the month of July, sixty-eight cases of cholera-morbus were reported, by less than twenty-eight physicians. Affections of the bowels continued prevalent till winter; several cases occurred that very much resembled Asiatic cholera. He believes that the wreckers were predisposed to cholera; and that their bad habits and exposure, and especially breathing the bad air of the vessel, charged, as he believes, with idio-miasm, were the exciting cause of the disease. Among the guard and negroes left on the island he supposes the same predisposition existed, and that alarm and military disorder were the exciting cause in these.

The physicians, three in number, sent down from Charleston suffered from nothing but fatigue.

The following report has been claimed as supporting the doctrine of contagion:

In Columbia, Pa., 1854, the cholera appeared in a single house, and several persons died of it. This house was destroyed by the authorities; no other cases occurred for some weeks, though there was a tendency to diarrhœa among the inhabitants, and cathartic medicines were unusually active. At length, on the 6th of September, two German emigrants were left at the dépôt sick with cholera, one of whom died. The vessel in which they had crossed the Atlantic had cholera on board. On the night of the 8th, two cases occurred among the inhabitants, both in unhealthy men, one of whom had had diarrhœa for a fortnight. "At midnight," says Dr. Smith, "it made its appearance in almost every section of the town, and at daylight there were thirty cases, all of which proved fatal during the 9th. Of those who fell under my care, I noticed many whom I had seen in the room with the German emigrants during their illness. Most, if not all, had diarrhœa the day previous." The town was on a bad site, and in a bad sanitary state. Intermittent and remittent fever was prevailing at the time.

Dr. Jackson states that a gentleman from Bainbridge, seventeen miles distant, visited Columbia while the cholera was prevailing, returned home, and died of it. His family fled; a friend who took care of him, contracted the disease, as did another who assisted at the burial. Neither of these two had been at Columbia or any other place where cholera was prevailing. Hundreds, Dr. Jackson adds, left Columbia at the height of the epidemic, and some had the disease in their place of refuge; but so far as could be learned, in only one or two cases did it appear to be communicated.

Of the physicians, one died; he was attacked on the first day of the epidemic, and died on the second. One nurse was attacked. All the other physicians, the officers of the Sanitary Committee, and nurses in private houses and in the town-hall, escaped.

Such are the facts and cases that are cited in support of the theory of contagion. Now, on the other hand, I will give you some statements and reports that seem to be altogether incompatible with the idea that the disease is communicable by personal contagion.

It will occur to your own reflections, that if cholera was contagious in Cumberland or in Columbia, it will be contagious everywhere. Typhus is contagious in dwellings and in hospitals, in village and town, in summer and in winter. If the term "contingent contagion" means anything, it can only be used in relation to the state of the individual—his power to resist contagion. The contagious principle is always the same; contingency cannot be predicated of it; nor is it apposite to say that one affirmative fact outweighs scores of negative ones, for the facts in this case are the occurrences of cholera as described. These are not doubted. The question at issue is, will these occurrences admit of any other explanation than the supposed contagion? If, then, it can be shown that in the broad study of the disease it is not spread directly by emanations from the sick, then the occurrences at Cumberland must have some other explanation, whether we have knowledge enough to make that explanation or not.

Dr. Morris states that in the Massachusetts State Prison, at midnight, July 27th, 1854, he was called to see a colored convict suffering from a choleraic attack. *He had been in solitary confinement for seven years.* Before Dr. Morris could get to bed again, he was called to four other prisoners, who had been attacked in different parts of the prison. During the next day, the succeeding night, and the following day, the cases multiplied; so that, in forty-eight hours, two hundred and five were more or less severely affected. The symptoms, Dr. Morris says, were "lividity of the lips, painful cramps, vomiting and purging, cold extremities, and in a few instances suppression of the urine." On the 27th of July, the day had been very hot, and by a sudden change the night was very cold.

A man who had been confined seven years in his cell, having no communication even with the prisoners in the institution, is the first to be seized. Suspicion was aroused that the food might be poisonous, but on examination it was found good and wholesome.

Dr. Trask gives the following account of the outbreak of cholera in the Westchester Poor-House, in 1849:

"Up to this time (the time of the outbreak), there had been no case of cholera, so far as I can learn, between this place (White Plains) and New York (twenty-eight miles), nor was there any evidence of its introduction from that city."

Suddenly, two men sleeping in beds almost adjoining, were seized with cramps, vomiting, and diarrhœa, after midnight, and before noon, both were dead. On the same day a female at the opposite end of the establishment was similarly attacked, and died in twenty-four hours. There were forty-seven cases, and twenty-seven deaths, among about one hundred and fifty inmates. He soon learned that diarrhœa had been prevailing in the establishment, and that most, if not all of those suddenly attacked had had this affection for some time.

Parallel instances could be multiplied indefinitely. The whole history of cholera seems to look to another cause than contagion for its origin. As it began in European towns, it was almost always preceded by

diarrhœa and colicky pains, and occasionally by cholera-morbus; and when at length it mad · its appearance, it often seized upon some person or persons who had not been out of town for a long time, between whom and infected places no connexion could be traced, living in a very unhealthy locality; and at very nearly the same time other persons were seized in similar negative relations to the outside disease, and who had had no communication with the person first attacked.

The settlement of the question can be somewhat aided by considering the history of hospitals, and the liability of nurses and physicians to the disease. Dr. Vanderveer gives an account of a little hospital of which he had charge in Franklin street, in this city, in 1854, where, it would seem, were assembled all the conditions necessary to give contagion force, if the disease is communicable in this way. He states that he had two wards, one above the other, the lower 25×35 feet, the upper, 25×30; that there were at times twenty-five patients in each of them; that the physicians and nurses slept in small adjoining rooms opening into the wards, and that the doors of their rooms were constantly open for ventilation; that the back yard, 20×30, inclosed by a wall twelve feet high, furnished room for the kitchen, water-closets, autopsy-room, wash-house; and a part of this space was reserved for the dead bodies, which were accumulated once to the number of ten, and till they became offensive. He says that the physicians made seventy-eight *post-mortem* examinations; that their hands, *bathed in the choleraic fluids, were often wounded*; that there were twenty physicians, nurses, and attendants, and that the only one of the twenty who had cholera, or any symptom of cholera, was a sedan-carrier of temperate habits, who resigned his place because his work was too hard, and five days after was brought to the hospital in a dying condition.

Here is a little pent-up place with water-closet, dead-house, and the dead piled up in coffins and exposed to the heat and sun, and shut in by a wall twelve feet high; the place full, the wards crowded, and the physicians and attendants, in effect, sleeping in the wards, and yet no one takes the disease. Histories of hospitals which teach the same lesson, few, however so emphatically, could be accumulated in our own country. From the European hospitals the same story comes. They do not all announce complete exemption of the physicians and attendants; but without any exception, the mortality is declared to be moderate—not exceeding what should be ascribed to the general liability, aided by fatigue and loss of sleep, and, on the part of nurses and attendants, often by intemperate habits. The physicians of cholera hospitals are rarely contagionists. The history of cholera hospitals does not sustain the doctrine of contagion; and here, if anywhere, contagion should be demonstrated. Out of almost countless reports that authorize these statements, I select the following table drawn up for the report of Drs. Gull and Baly, referring to the general hospitals of London in 1849.

Examine this Table attentively. Guy's Hospital did not admit persons attacked with cholera; yet one in 163 of its inmates, and one nurse to 490 patients, died of that disease. Five of these institutions admitted the disease, but confined the patients to particular wards. They had an aggregate of 1466 general patients, and 381 deaths from cholera. Multiplying the deaths by two, the usual hospital ratio between cases and deaths, the product, 762, will be about the number of cholera patients admitted. The deaths by cholera among other patients were one in 147, and among nurses one to 371 patients, including those admitted with cholera. Three hospitals, with an aggregate of 750 patients, received probably about 150 persons sick with cholera (deaths seventy-seven), and they were distributed among other patients. The deaths among these other patients were three, or one in 250; and of the nurses only one to 900 patients died.

Hospital.	*No. of Patients.*	*No. of Deaths among Patients admitted with Cholera.*	*No. of Deaths from Cholera among other Patients.*	*No. of Deaths by Cholera among Nurses.*	*How the Cholera Patients were distributed in the Hospital.*
Guy's Hospital.....	490		3	1	No Cholera patients admitted.
St. Bartholomew's.....	500	193	1	1	Cholera patients in special wards.

St. George's Hospital.....	300	11	Two Surgical and one Medical.	1	" " " "
Westminster Hospital.....	150	37	None.	None.	" " " "

Throughout England, indeed all Europe, and from our own country, the testimony is cumulative, and to the best of my recollection nearly uniform from cholera hospitals, that nurses, while they incur the general risks during an epidemic, aside from the effects of fatigue and the excessive use of intoxicating drinks, are not in any degree specially exposed to the disease. I may say, in parenthesis, that I believe there is no fact better established than that intemperate persons are especially liable to cholera. The same statement may be made of those who are employed in rubbing and bathing the sick; of those who empty and cleanse the vessels which receive the discharges; of those who are engaged in transporting the sick, and of those who remove and bury the dead.

But there is a class of nurses and attendants who are more exposed to the disease than those who are usually employed in cholera hospitals. I refer to such as are

engaged in the service of the sick within institutions when the disease has become epidemic. An example or two will make the point clear. In seventeen public lunatic asylums in England (Baly and Gull, 1849) visited by cholera, the total number of patients was 3639; of these 454 were attacked, and 311 died. In the same seventeen institutions there were 407 nurses, attendants and resident officers, of whom eighteen were attacked and six died, or thus—

Attendants attached,.....	1 in 23;	died,.....	1 in 68.
Patients "	1 in 8;	"	1 in 12.

In the Milbank prison, containing at the time 1107 prisoners, twenty persons were charged with the care of the sick, and there were 178 persons who were by their offices not brought in contact with them, or only occasionally. The deaths among the prisoners were forty-eight, or one in twenty-three; among the nurses one, or one in 20; among other persons (including guards, clerks, etc.,) one, or one in 178. Take these two accounts together and it is clear that, so far as the evidence goes, in institutions where cholera is epidemic, nurses are no more liable to the disease than other inmates, making exception for those whose hygienic surroundings were of a more protective character—indeed, in the lunatic asylums, that they were greatly less liable than others; while the one death in the prison makes a very unimportant figure in the statistical estimate on the positive side, though significant in its negative relations.

It does not appear that physicians who are attending cholera patients are more liable to the disease than others; indeed physicians seem to possess more than usual immunity. The number who have died in this city in the various epidemics is small. I have no statistics at hand to guide me, but I am confident that the percentage of mortality among them is less than among persons in the same social rank unconnected with the profession.

Dr. Buel says, referring to the epidemic of 1854, of the Centre street and Twenty-third street hospitals, "there were at different times eight or nine medical attendants, several of whom spent their whole time in the hospitals, eating and sleeping there, and no one took the disease;" and then adds, "among the physicians attending five cholera hospitals, and the various other public institutions in which cholera prevailed extensively, there was not a fatal case, and only two were heard of that had the disease." How sadly the records of typhus fever contrast with these statements, let the honored names engraven on the mural tablet in this Hall testify; let the stricken families, that by a dire conscription are forced to contribute, year by year, their brightest ornament to swell the list of professional victims; let the bereaved and mourning, on whom my words now fall like the knell whose echoes have scarcely ceased, bear witness. An epidemic typhus in a hospital, I might almost say, spares none; while epidemic cholera in hospitals assails so few, that we find no danger in such service beyond what pertains to the general epidemic influences.

In considering facts like these, then, we are obliged to modify the opinion that might be formed from such striking instances as those of the Tooting School and those at Cumberland. Such occurrences can, indeed, be explained upon the general doctrine that there was an atmospheric condition that predisposed to the disease, and that the elements of the special poison were present and ready to combine whenever the ferment should be introduced; and that the ferment was in some way brought by the infected persons to each locality. In the case of the Tooting children, however, the disease did not become epidemic, strictly speaking, in more than one of the five institutions. In the others, one to several of the "attendants" suffered from the disease. In these instances the poison may have been imported, and not reproduced. This view receives support from the fact that "several asylums and workhouses to which the Tooting children were sent were not visited by the disease," although children died in them.

There is another point that I must speak of, relating to the communicability of cholera. Drs. Baly and Gull directed particular attention to the question whether washerwomen, who were employed in purifying the clothes soiled by cholera patients, were particularly liable to the disease. They state that they had eighty-four communications relating to this matter; that in general when washerwomen took the disease, they were surrounded by the same influences that produced it in others, and it was difficult to determine whether there was any special danger in their occupation. They sum up by saying there were only seven instances in the eighty-four in which the evidences seemed fairly to establish connexion between cholera and the clothes. At the same time they say the women who washed the clothing for the Tooting children escaped entirely; and of the thirty women in the laundry of the Milbank prison, not one was affected; while of one hundred women employed in other capacities through the prison, eight took the disease. The liability, then, even for the washerwomen, is not very great; it is perhaps a little greater than for nurses, as it is a little more for nurses than for physicians. But even if it were established that this occupation is especially dangerous, further inquiry would be necessary to determine whether the danger arises from a personal poison or a miasm imported with the clothes.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

RESOLUTIONS ON THE DEATH OF THE LATE PRESIDENT, DR. JOSEPH M. SMITH.

A SPECIAL meeting of the New York Academy of Medicine was held in the lecture-room of Dr. Rice's Church, corner of Fifth Avenue and Nineteenth street, on Tuesday, the 24th ult., for the purpose of taking action concerning the death of their former President, Dr. Joseph M. Smith. The President, Dr. James Anderson, called the meeting to order, and Dr F. A. Burrall was appointed Secretary *pro tem.*, after which the President alluded briefly but feelingly to the circumstance which had called the members of the Academy together.

Doctors E. Delafield, Bulkley, and Loomis were appointed a Committee to present appropriate resolutions; and Doctors Bibbins, E. B. Belden, and W. H. Draper, a Committee of Arrangements.

In offering the resolutions, Dr. Delafield remarked that he was called upon to perform a grateful though painful duty. He felt painfully the loss of a friend with whom he had been associated for many years in the same institution and in ministering to the sick. He had enjoyed and valued the friendship of Dr. Smith, and no human being could speak ill of the beauty of his character, his amiability and worth. Dr. Smith had lived a long life, had made friends everywhere, and enemies nowhere. His reputation as a consulting physician was extensive, and those physicians who called him in consultation knew that they would meet a man of learning, a gentleman, and one who was worthy of their confidence. Yet he did not rise to eulogize the deceased, and would offer the following resolutions:

Resolved, That the Academy has received the an-

nouncement of the death of Dr. Joseph M. Smith, formerly President, and many years one of the most distinguished members of their Association, with the deepest concern.

Resolved, That, although after a life passed in the exercise of his professional duties in a manner always honorable to himself and acceptable to those to whom he ministered, the loss to his family and friends must still be severe and their grief heartfelt; they have much ground for consolation in the recollection that the well spent life of their departed friend has only terminated after a period not very often reached by our race.

Resolved, That apart from the high professional reputation always enjoyed by Dr. Smith, both as a practitioner of medicine and one of the ablest teachers of his day his excellent private character, his many Christian virtues, his uniform courtesy and honorable intercourse with his fellows, have endeared him to the entire profession of the city, as well as to a large circle of private friends.

Resolved, That while the Academy deeply sympathize with his family in their bereavement, they, with all his other friends, feel confident that when time has softened the sadness of parting, the memory of his life will be an enduring source of comfort and pleasure to those from whom he has been taken away.

Resolved, That the members of this Academy will attend the funeral of the deceased, and that the usual badge of mourning be worn on the occasion.

Resolved, That a copy of these resolutions be presented to the family of our late member, signed by the officers of the Academy.

Dr. J. H. Griscom rose to second the resolutions, and referred to the estimable character of the deceased. Was there among us, he asked, a man more amiable, virtuous, or intelligent than Dr. Smith had been? He confessed his own inability to mention such a one. Dr. Smith was cordially prized by all who knew him.

The resolutions were unanimouly adopted.

Dr. W. C. Roberts then observed:

Mr. President: I cannot refrain from offering my humble tribute to the memory of the good man whose loss we are this day assembled to mourn. I have known him more than forty years. I have been many times in intimate professional relations with him, and can speak of him as truly and estimate him as highly as many of my older professional brethren who knew him better. Who that ever aproached him was not charmed with the sweetness and softness of his manner, his courteous and dignified affability, his kind and considerate interest wherever his advice was required, and the delicacy with which that advice was given. At the bedside, how gentle and patient; in investigation, how painstaking; in diagnosis, how accurate; in pathology, how perfect; in practice, how ready and judicious. No one more thoroughly respected the feelings and interests of his professional brethren than Dr. Smith. To his brethren he was *decus et tutamen*, and they loved and honored and treated him accordingly. He had neither enemies nor detractors. Dr. Smith was a learned scholar, an industrious, able, and eloquent writer, and an agreeable speaker. His contributions to medical science are numerous, varied, and valuable, of which the most noted—his Philosophy of Epidemics—will ever remain an imperishable monument of his research and learning.

His zeal and services in the Sanitary Commission, and his long and benevolent hospital service, bear witness to his philanthropy and disinterestedness. The purity of his life and mora's testifies to the exalted religious influence by which his life was governed. He was a Christian physician, citizen, husband, father, and friend. He leaves us now when we never could have loved him better, at a ripe old age, after an active, useful, and prosperous career, in the fulness of professional honor, alike beloved and regretted by his professional brethren and fellow-citizens. We cannot sorrow that he has gone thus to reap the rich reward of his long and faithful services, and has entered into the joy of his Lord; but we can cherish the remembrance of his gentle kindness, of his merits and his virtues; we can imitate his example, and to his younger brethren and those who are to come after him we may say, "Go ye and do likewise." Mr. President, I fully concur in the resolutions.

Remarks were also made by Drs. Bulkley and Raphael.

On motion of Dr. Henschel, the meeting then adjourned.

James Anderson, M.D., President.
F. A. Burrall, M.D., Secretary *pro tem.*

Adjourned Meeting, April 26, 1866.

James Anderson, President, in the Chair.

CHOLERA—ITS CONTAGIOUSNESS, RELATION TO QUARANTINE, ETC.

Dr. Harris, by request of the Academy, gave an account of his visit to the cholera-ship Virginia. He stated that this vessel belonged to the better class of emigrant ships, and he would reiterate this statement, since his former duties had familiarized him with the various differences in these structures. The Virginia sailed from Liverpool on the 4th of April, calling at Queenstown for a company of Irish and Welsh on the succeeding day. The passengers—1029 steerage, 14 cabin—were of the better class, and principally from Holland and Germany. They came on board in a perfectly healthy condition, and so remained until the 12th April. On that date the first case of what was subsequently recognised as epidemic cholera occurred on the orlop deck, which is below the water-line, in the person of a robust Hollander from Elfis, near Rotterdam, who died after a few hours' illness. A woman who was noticed as being in a feeble condition when she embarked, and a child, soon shared a similar fate. Eight deaths with the usual choleraic symptoms occurred on the 13th, and the mortality continued up to the 18th, when the vessel made this port, at which time 37 had died. Beyond the simple notice of the deaths as they occurred, no record of the cases had been kept. On his visit he noticed less suffering from muscular cramps than usual, and the patients seemed to be by no means panic-stricken. Owing to the want of a good linguist, conversation with the passengers was difficult, and not much information concerning the personal habits of any patient was gathered. The epidemic could not be traced with certainty to any locality where it had recently prevailed, although some of those who came from Altenberg and Werden appeared to know more in regard to the matter than they chose to disclose.

By referring to Dr. Burrall's work on "Asiatic Cholera," it will be found that the epidemic which broke out in Altenberg, Sax-Altenberg, and Werden, during the past winter, came from Odessa on the Black Sea.

Dr. Griscom maintained that the cause of this choleraic outbreak resided within the ship itself; that his view regarding the operation of two agents, the one atmospheric and the other local, was still unchanged; and that in this particular instance, under the various depressing influences of insufficient ventilation, and an overcrowded steerage beneath the water-line, with little if any light, he would expect an epidemic of typhus fever at the very least. He was well convinced, too, that cholera followed the track of typhus fever, and that here some peculiar mysterious condition of the atmo-

sphere substituted cholera for that other equally fatal pestilence. He would call attention to the fact that the cabin passengers, who as a class are generally exposed to brisk currents of air on deck, and have the benefit of free ventilation when not thus enjoying themselves, were here also exempt from any choleraic visitation.

Dr. Harris, in reply to a question regarding the treatment employed on board of the Virginia, stated that it was exceedingly simple; that stimulants and capsicum, in conjunction with perfect repose, were mainly employed by the ship's surgeon. These means, he would state, were sometimes followed by gratifying results, more particularly before the stage of collapse had been established, at which time the case was looked upon as desperate, and all remedies regarded as equally unpromising.

Dr. Hubbard inquired whether the cholera was capable of being communicated to others through the medium of a healthy individual who had been exposed to the poison.

Dr. Harris did not expect on the occasion of his official visit to the Virginia to be seized with the disease, since he considered that his physical powers were at the time in excellent condition, and that a considerable amount of exposure would be requisite before a lodgment for the virus could be effected. He as well as other members of his staff had, however, suffered somewhat from the preliminary diarrhœa when on duty at the Quarrantine some years ago; but then an explanation might be found in the fact that, despite all exertions to the contrary, the privies were never in a condition incapable of propagating infection.

Dr. Herzog called attention to certain cases where individuals perfectly well, or to all intents and purposes so regarded, introduced the disease from infected districts to other communities. He would venture the statement, that in the instance of the Virginia those reticent passengers, from Altenberg and Werden, in Saxony, could not have been ignorant of the epidemic which had raged there during the past winter. The persons of the escaped passengers from the quarantine ship at Halifax he would regard as just so many sources from which the disease might emanate. The popular instinct which prompts the giving of a wide berth to all sick or well who have been thus exposed, was nothing more than an exemplification of the self-preservative principle in nature.

Dr. Bibbins desired that the material points of a case cited by Professor Alonzo Clark in his recent lectures upon cholera might be remembered. It was to the effect that an epidemic began in the person of a convict who had passed seven years in solitary confinement. This fact he considered an argument in favor of the non-contagiousness of the disease.

Dr. Underhill, soon after his entrance upon his professional career in June, 1832, received a summons to attend two emigrants from Quebec who had been suddenly stricken down by the disease. A professional brother whom he thought it advisable to call to his aid, along with himself, remained with the patients until their death, which took place after the lapse of some hours. A panic in the neighborhood deprived them of nurses, both paid and voluntary; and in the emergency, actuated by motives of humanity, they substituted their own services in addition to the offices of the physician. During his novitiate he had read every authority upon the subject of cholera that could be obtained by him, and had become a non-contagionist in creed, so that upon this occasion he did not take any particular pains to guard himself against exposure. In short after a warm bath upon retiring, he awoke much refreshed, and escaped without any symptoms of the disease. The experience of his colleague was identical with his own.

Dr. O. White then related several cases occurring in his experience, where the introduction of the disease could be traced to parties from infected districts. One was that of a stage-driver from Harlem, who died soon after arrival in one of the suburban towns, and was the recognised source of the local epidemic. Another instance was that of a family of five adults, about 100 feet from whose residence there occurred a unique case of cholera, which terminated fatally. This result worked upon the fears of the family to an unusual degree, and a majority of their number fell victims. This epidemic spread with virulence, and killed one out of every four that were attacked.

After some further remarks by Drs. Hubbard and Batchelder, and the passage of a resolution referring to the organization of the profession in the event of a choleraic visitation, the Academy adjourned, to meet on the second Wednesday in May.

Dr. Macready's remarks upon the *Physiological and Therapeutical Action of Alcohol*, having not yet been concluded, will be given *in extenso* upon the resumption of the discussion upon the subject.

Progress of Medical Science.

Acute Articular Rheumatism.—In an article entitled *Statistical Report upon Acute Articular Rheumatism*, Dr. A. Fiedler presents some facts as to the occurrence of this disease in the City Hospital of Dresden from the year 1850 to 1862, inclusive. The cases are from the medical division of the hospital under the care of Dr. Walther. Cases of chronic articular or muscular rheumatism are not included, since in these diseases we have probably to deal with entirely different morbid processes from those in the cases under consideration. The whole number of patients was 14,738, of which 651 were cases of acute articular rheumatism, or 4.4 per cent.

Dresden, in respect to other forms of disease, with perhaps the exception of typhus abdominalis, and tuberculosis, may be called a "healthy city." This is, however, not exactly true as to acute articular rheumatism; and in accordance with this fact, heart affections are more numerous there than elsewhere. As to the frequency of the affection in other cities the following may be said: in Stuttgart, it is 1.5 per cent; Würzburg, 1.5; St. Petersburg, 1.7; Bremen, 2; Rostock, 3.3; Zürich, 4; Hamburgh, 4.2–4.7; Giessen, 5; London, 11 5.

As to the sex of the Dresden patients, of 651 patients, 281 were men, 370 women. The time of year has without doubt great influence on the frequency of rheumatism. The months may be arranged in the order in which rheumatism most frequently occurs, as follows: 1. December and May; 2. November, January, March, February, April, and August; 3. September, July, and August. The most frequent period of life in which attacks occurred was from eighteen to twenty-five. The frequency was the greatest in the twentieth year. The youngest patient with rheumatism was twelve years old, but children are seldom admitted to this hospital. A great number of the cases of rheumatism were complicated with endo-or peri carditis; but according to Dr. Fiedler's view these complications are not adapted to statistical collections. The diagnosis of heart affection in rheumatism is often accompanied by great difficulties, and often it is impossible to decide with certainty, if an inflammatory process of the endocardium (and this is partially true as to the

pericardium) really exists: or if the heart sounds do not arise in the same way, and indicate the same as in other acute diseases, *e. g.* typhus, miliary tuberculosis, scarlet fever, measles, in which no inflammatory process, but only a want of innervation or a disturbance in nutrition of the cardiac muscles, is the origin. Frequently we hear in the most different acute and chronic diseases murmurs in the heart, which indicate an imperfect closure of the valves or a narrowing of the openings; and we are surprised on a post-mortem to find not the slightest lesion in the heart: exactly as in other diseases is it in rheumatism. Of these 651 patients only two died of rheumatism itself; one girl of twenty, and a man of twenty-seven. On the section no complication was found, and the death must be considered as from rheumatism. Death occurred frequently from secondary disturbances.—*Archiv für Heilkunde, Heft* 2, 1866.

Treatment of Syphilis with Mercurial Suppositories, by Dr. Tomswitz, surgeon in the Austrian army. Zeissl, in his text-book, page 377, remarks that lately, in such patients as those in which the inunction treatment was not allowable, he has used mercurial ointment in the form of suppositories. I have tried this remedy in the past year in fourteen exquisite cases of syphilis. Each suppository contained one scruple of the ointment, rubbed up with about half a drachm of white wax, about double the size of those used by Zeissl. One is placed in the rectum at the evening visit. The patients had a moderate diet, and were nearly the whole day up and about Moderate use of tobacco, when there was no throat affection, was not forbidden. The cases treated were as follows:—1. Papular syphilitic eruption, from 19th July to 25th August, 30 suppositories; 2. Psoriasis palmaris et plantaris, from 19th July to 20th August, 25 suppositories; 3. Rupia, 28th July to 18th September, 35 suppositories; 4. Macula, 22d July to 20th August, 20 suppositories; 5. Syphilis of mucous membranes, 3d August to 25th September, 34 suppositories; 6. Macula, 8th August to 10th September, 22 suppositories; 7. Macula, 8th August to 15th September, 30 suppositories; 8. Squamous syphilitic eruption (Schuppen), from 28th August to 25th September, 22 suppositories; 9. Syphilis of mucous membranes, from 6th September to 20th, 13 suppositories; 10. Squamous eruption, from 17th September to 25th October, 20 suppositories, etc. The result was in every respect highly satisfactory. No other treatment was necessary in any case. Salivation did not occur. In general I have found salivation to occur very rarely, since Sigmund's direction as to washing the mouth with cold water was energetically carried out.—*Allgemeine Militärischliche Zeitung, March* 11, 1866.

New Method of Reducing the Inverted Uterus.—Dr. Thomas Addis Emmet, Surgeon to the State Woman's Hospital, New York, has reported (*Amer. Jour. Med. Sciences*, April, 1866) a second successful case of reduction of inversion of the uterus by an original method. This operation was performed February 17, upon a patient in the St. Vincent's Hospital of this city, under the care of Dr. Gouley. "In June last, the patient was delivered by a very rapid labor, in which she had but one severe expulsive pain, just as the head was expelled." The after-pains were severe, and came on at once. From a short time after delivery until the reduction, there had been a constant show, which frequently amounted to a hæmorrhage, and she presented the appearance of one who had been suffering from an excessive loss of blood. Her condition had been attributed to the existence of a polypus, which was supposed to be protruding from the os uteri, and she had been sent to the hospital for the purpose of its removal. An examination readily disclosed the condition of things; and the patient being etherized, Dr. Noeggerath's method was first tried, and afterwards that of Prof. White, of Buffalo; but without success. It may be here remarked, the organ was so dense, and was contracted to so nearly its natural size, that the case was not a fair one for testing either of the modes. Finally, Dr. Emmet employed his method, an idea of which is conveyed in the following description which he gives of the operation: "With the left hand in the vagina, the four fingers were passed as far up as possible between the inverted portion and the neck, with the thumb in front, so that the body was encircled by the fingers, and the fundus rested in the palm. Then, with an upward and outward pressure at the same time, the neck was gradually dilated until the seat of inversion was reached by the frequent extension of the fingers. This manœuvre was persevered in, while during the whole time the organ had been lifted above the pubes, so that the other hand could assist in the rolling out of the parts by sliding upwards the abdominal walls, with a steady pressure over the posterior portion of the ring formed by the inversion. In less than half an hour the mass, as felt through the abdominal parietes, had doubled in size, the depression in the centre had become larger, and the shape changed from a circle to an oval. The fundus gradually passed entirely within the cervix; but after this the progress, as appreciated from the fingers within the uterus, was almost imperceptible; but the rapidly-increased size of the mass and the diameter of the depression at the seat of inversion was recognised by all present."

At the end of an hour, the hand of the operator became powerless, and Dr. Noeggerath was asked to complete the operation, which he succeeded in doing in about ten minutes.

The patient entirely recovered. Dr. E. is satisfied that it is beyond the power of endurance for one person to complete the reduction, especially in a long-standing case, without assistance, and advises that a change of hands should be frequently made. Dr. Emmet's first case is reported in the same journal for January.

Trichinosis.—Dr. Pleische, of Vienna, recommends the use of fomentations of common salt in Trichinosis. This is the remedy which *Laennec* used in cases of echinococcus. Dr. P. recalls two cases where the latter-named parasite infested the liver, occurring in Professor Oppolzer's clinic, where favorable results followed this treatment. One of the patients still lives in Vienna in good health Compresses are moistened in a solution of common salt, covered over with flannel, and applied where the local symptoms manifest themselves. Where slight or no fever exists, salt water baths might be taken, and even salt administered internally in three to four drachm doses.—*Viener Medicinische Presse, Feb.* 18, 1866

THE MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

THE proceedings of the last meeting of the American Medical Association, which appear in full in our present number, will, no doubt, be read with interest by every one. As the representative medical body of this country, its doings must be acknowledged to possess no small influence upon the profession on the Western Continent.

Many matters, great and small, have been discussed; and the various decisions that have been made in the premises are now on record, and must commend themselves or not to the adoption of the profession in proportion to the amount of wisdom and sound judgment that have been displayed by the parties concerned.

There are some points in these proceedings which invite from us a passing comment.

A greater part of the morning session of the first day was occupied with Dr. PALLEN's case, the details of which are already familiar to our readers. The discussion was quite animated, and the final action taken was very proper. The Association not only received the injured Fellow into full membership again, but expressed regret at the hasty action taken at the meeting in Boston.

The subject of specialism also claimed not a little of the time of the Association. No definite action, we are glad to say, was taken upon the matter, notwithstanding the well pointed arguments urged by the opposing parties in favor of their several views. The discussion might have been never-ending had not the gentleman from Philadelphia, Dr. COHEN, secured the passage of the resolution to lay it on the table for a special order of business during the next annual meeting. We, however, doubt whether the Association will be able to dispose of the subject even then. In fact, with such a radical difference of opinion in the two parties concerned, we may never hope for a proper solution of the vexed question. These differences of opinion were pleasantly enough presented; but no one not directly interested could fail to appreciate the existence of a very deep and strong current of feeling which every moment threatened to undermine the very best of intentions.

The subject of Cholera was also taken up, and as it seemed to be the intention of the Association to fully discuss the disease, all were prepared, not only for an interesting presentation of facts, but for some intelligent and enlightened action upon such facts. More especially was it hoped that this would be the case with regard to the expression of an opinion as to the utility of quarantine; but, alas! disappointment awaited all those who were sanguine on this point. The non-contagionists, with a narrow-mindedness that was truly remarkable, refused to recommend even the testing of the utility of the measures proposed by Dr. MARSDEN, of Quebec. The original mover of a resolution to bring the matter to the notice of Congress and recommend action in the matter, although he had no intention of committing the Convention to any idea of contagion, had seemingly such an object in view. We were not surprised, then, to find that his recommendation was not endorsed. The resolution would have been laid at once on the table had not Dr. BURGE, of Brooklyn, come to the rescue in a conservative amendment. This amendment was perfectly non-committal, its intention merely being to prove to the Executive that the Association believed enough in any quarantine plan to desire a fair test of its utility; in other words, that it wished to be on the safe side in countenancing such a perfect plan of quarantine as was recommended by Dr. MARSDEN. The amendment was, with shame be it said, tabled.

We might allude to other matters, such as the subject of Medical Education, for instance, but this is too extensive a subject to discuss in our necessary brief comment, and so deferring it for a more convenient season, we must hasten to close our remarks.

The meeting was pretty largely attended, but there was by no means such a number present as we had expected there would be. We regretted to see so many seats vacant that should have been filled by Southern medical men. Although this was the case, we have every reason to hope that better times are coming, at least judging from the kind feeling towards the Association expressed by those few who were present.

We would not be doing justice to the profession of Baltimore, to the Corporation authorities, and to the Executive of the State, were we to omit allusion to the elegant and refined hospitality which they tendered the members of the Association during their sojourn.

IN consequence of the very full report of the meeting of the American Medical Association, we have been compelled, in order to have room for other "copy" which also "must go in," to make an addition of eight pages of reading matter to the present number. To this we do not suppose that any of our readers will

object. But as the practicability of making the addition was decided upon rather late in the day, we fear that our subscribers will not get their numbers with usual promptness. We hope, however, to be able to mail the issue on or before the 14th inst.

American Medical Association.

FIRST DAY.—MAY 1.

The Seventeenth Annual Meeting of the American Medical Association was held in the city of Baltimore, at Concordia Hall.

The Association was called to order at 11 A.M., Tuesday, May 1, by the President, Dr. D. Humphreys Storer, of Boston.

On motion of Dr. Bissell, of New York, the ex-Presidents and ex-Vice-Presidents were invited to take seats on the platform.

The Rev. Dr. Spies, of Baltimore, was introduced, and opened the meeting with prayer.

Dr. C. C. Cox, on behalf of the Committee of Arrangements, in an eloquent address, gave a warm welcome to the Association, and hoped that when the short stay of the members was ended, they would have cause to retain kindly remembrances of the Monumental City. He expressed his regret that so few delegates from the South were present, and hoped that now that peace had come, they would again return, and aid the Association with their learning and experience in the great work the profession had before it. He paid a high compliment to the fidelity of the surgeons on both sides during the late war, and referred in pathetic terms to the many learned men who have been taken away by death since the Association met in Baltimore eighteen years ago, and closed by again warmly welcoming the visiting brethren.

THE CASE OF DR. MONTROSE A. PALLEN.

Dr. Cox then offered certain documents exculpating Dr. M. A. Pallen of Missouri from the charges brought against him at the meeting in Boston, and for which he was then expelled.

On motion of Dr. W. Jewell, of Pennsylvania, the order of business was suspended, in order to allow these to be received.

Dr. Cox moved that the papers be referred to the Committee on Medical Ethics, with a request that they report promptly.

Dr. Ordway, of Boston, was disinclined to have the subject go before a committee, and contended that Dr. Pallen should be as speedily and publicly invited to a participation in the business of the Association, as he had been hastily and unjustly expelled at the previous meeting.

Dr. Davis, of Illinois, favored the reference, because he thought, as the action of last year had been placed upon the record of the Association, that all the action reviewing the work of that meeting affecting Dr. Pallen should be fully spread upon the record. He would like to have it referred to the Committee on Ethics, with instructions to report as early as practicable.

After much discussion, the whole matter was finally referred to the Committee on Ethics, with instructions to report forthwith.

Dr. Worthington Hooker, of New Haven, stated that he was the only member of that committee present; whereupon Dr. Brinsmade of New York, and Dr. Davis of Illinois, were added to the committee.

Dr. Thomas E. Bond, of Baltimore, moved that the committee to whom was referred the case of Dr. Pallen be instructed to report the expression of most profound regret that the Association should have been hurried into its unjust action to Dr. Pallen; and that they express the hope that Dr. Pallen would accept such acknowledgment as an expression of a frank apology for the great wrong done him. This, together with an amendment, was laid on the table.

Dr. William B. Atkinson, of Philadelphia, the Permanent Secretary, then called the roll of members.

On motion of Dr. Cox, it was determined that the successive morning sessions of the body should commence at nine o'clock. He afterwards announced the arrangements which had been made for the meeting of the several sections during the afternoons.

Also, on motion of Dr. Cox, Dr. James E. Reeves was invited to a seat with the Convention.

Dr. Bond on motion, then brought up his motion with reference to Dr. Pallen.

Dr. Storer, of Massachusetts, explained that the charge against him was not of disloyalty, but that he had been guilty of the grossest unprofessional conduct in an attempt to poison the Croton Aqueduct.

Dr. Jewell, of Philadelphia, called the gentleman to order, saying that the resolution of Dr. Bond was out of order.

Dr. Holton, of Vermont, thought it rather strange to appoint a committee to report in the premises, and then instruct them how to report.

The suggestion of Dr. Bond, which had been incorporated into a resolution, was finally laid on the table.

Dr. Hooker, Chairman of the Committee on Ethics, then presented the following report, which, after being warmly discussed by Drs. Owens and Bond of Maryland, and Tyler of Washington, was finally adopted:

"The Committee to whom were referred the papers in relation to the expulsion of Dr. Montrose A. Pallen, at the meeting of the Association in Boston, respectfully report:

That they have examined the documents and evidence referred to the Committee, embracing papers endorsed by General U. S. Grant, the Vice-Consul of the United States at Montreal, and many citizens of Missouri, and are fully satisfied that the statements on which his expulsion was based were entirely unfounded; and, therefore, regretting the injustice done, both to Dr. Pallen and the Association, we recommend the following resolution:

Resolved, That the preamble and resolution adopted by the Association at its annual meeting in Boston, June, 1865, expelling Dr. Pallen, be hereby rescinded; and that Dr. Montrose A. Pallen be restored to his previous membership in the Association."

On motion of Dr. Ordway, a Committee of Three was appointed to wait upon Dr. Pallen, and inform him of the action taken in his case; and on motion of Dr. Owens, Dr. Cox was made chairman of said committee.

Dr. Pallen was then presented to the Association, and thanked them in an appropriate and feeling manner for the action they had taken in regard to his case.

THE PRESIDENT'S ADDRESS.

Dr. D. Humphreys Storer, the President, followed with his annual address. His subject was that of Specialties in Medicine. The ground which he took was one of encouragement to all such worthy and qualified young men as chose to confine their particular attention to one branch. The address was a well written and interesting one, and commanded the most respectful attention of all present.

On motion of Dr. Holton, of Vermont, the thanks of the Association were tendered to the President, and the address was referred to the Committee on Publication.

The reports of the Special Committees were then

called for, and all the papers that were presented were referred to appropriate sections.

The following voluntary papers were then in turn offered, and in like manner referred: "On Luxation of the Hip-Joint, Nine Months' Standing, etc.," by Dr. L. A. Sayre, of N. Y.; "On Improvements in Water Pipes," by Dr. J. C. Draper, N. Y.; "On Extirpation of the Uterus," by Dr. H. R. Storer, of Boston; "On Permanganate of Potassa as a Purifier," by Dr. Craig, of D. C.; "On the Application of Local Anæsthesia to Practical Medicine," by Dr. J. Solis Cohen, of Philadelphia; "On Aluminium in Dentistry," by Dr. Mason, of Mass.; and "On Exsection of Lower Jaw," by Dr. D. C. Enos, of N. Y.

On motion of Dr. Cox, Dr. E. Brown-Séquard was invited to deliver a lecture before the Association upon the treatment of nervous diseases at 11 A.M., on Wednesday.

On motion of Dr. Davis (Ill.), Dr. H. Marsden, of Quebec, was elected a member by invitation, and invited to a seat upon the platform.

The meeting then adjourned to meet at 9 A.M. on Wednesday.

PROMENADE CONCERT.

During the evening a promenade concert was given to the members of the Association by the Committee of Arrangements, at Concordia Hall. Although the evening was a stormy one, the attendance of ladies and gentlemen was unexpectedly large. At the conclusion of the concert, the company was regaled by a magnificent supper.

SECOND DAY.—MAY 2.

The Association was called to order by the President, Dr. D. H. Storer, at 9 A.M.

The Committee on Epidemics, Meteorology, etc., having been called upon, Dr. Davis stated that Dr. Hamill had presented a report which he had taken to the Section on Epidemics, etc.

Dr. Cox made an additional report from the Committee on Arrangements on Railroads, that invitations had been received from Drs. Smith and Donelson, for the members of the Association to visit their houses that evening. He also recommended the following gentlemen as members by invitation: Drs. Jno. A. Reed, W. Whitridge, L. M. Eastman, of Baltimore; Peter Parker of China. They were elected.

On motion of Dr. Davis, the order of business was suspended.

The report of the Committee on Publication was read and accepted.

On motion of Dr. Sayre, of New York, the Publishing Committee were authorized to enforce strictly due care in regard to proofs, etc.

The Treasurer then read his report, which was referred to the Committee on Publication.

On motion, the order of business was resumed.

On motion of Dr. Davis, a recess of fifteen minutes was taken by the Association, to allow of the appointment of members of the Nominating Committee.

THE NOMINATING COMMITTEE.

On the resumption of business, the following members of that Committee were announced:

J. C. Weston, Me.; J. C. Eastman, N. H.; Wm. McCollim, Vt.; J. R. Bronson, Mass.; D. King, R. I.; W. Woodruff, Conn.; J. C. Hutchinson, N. Y.; W. Pierson, Jr., N. J.; H. F. Asken, Del.; John L. Atlee, Pa.; J. J. Cockrill, Md.; M. A. Pallen, Mo.; N. S. Davis, Ill.; W. Lockhart, Ind.; J. M. Withercone, Iowa; N. R. Bozeman, Ala.; C. M. Stockwell, Mich.; H. Van Dusen, Wis.; T. A. Atchison, Tenn.; G. Fries, Ohio; G. Tyler, D. C.; W. M. Charters, Geo.; J. Simpson, U.S.A.; N. Pinkney, U.S.N.; Greensville Dowell, Texas.

Dr. W. Hooker offered the following resolution, which was unanimously adopted:

"*Resolved*, That no report or other paper shall be presented to this Association unless it is so prepared that it can be put at once into the hands of the Secretary, to be transmitted to the Committee on Publication."

Dr. Wister, of Pa., offered the following, which was adopted:

"*Resolved*, That Drs. Grafton Tyler, W. P. Johnson, and Jas. M. Toner, of D. C., be a Committee to procure a room in the Smithsonian Institution, for the preservation of the Archives of the Association."

The Committee on Medical Education not having prepared a report, Dr. J. F. Hibberd offered instead thereof the following preamble and resolution, and moved that it be adopted as the sentiment of the Association:

"*Whereas*, Two-thirds of the Medical Colleges of the States of Ohio, Michigan, Illinois, Iowa, Missouri, Kentucky, and Tennessee, by delegates in convention assembled in Cincinnati, on the 24th of April ult., did, by resolution unanimously adopted, declare their willingness to make their annual college sessions to continue for six months, and to establish a uniform rate of fees, if the other principal colleges of the country will coöperate; now, therefore,

"*Resolved*, That the American Medical Association hereby expresses its warmest approbation of the action of the above recited colleges, and expresses the hope that every Medical College in the Union will concur in the proposition thus made."

On motion of Dr. Taylor, of Iowa, its consideration was postponed till 11 A.M. on Thursday, to be acted upon in Committee of the Whole.

Dr. C. A. Lee, of N. Y., commenced reading his report upon Medical Literature. He divided up his subject as follows: I. Periodical Medical Press. II. Medical Literature of the War. III. Literature of the Sanitary Commission and of Sanitary Sciences. IV. State and County Society Transactions. V. Literature of Special Subjects and of Specialties. VI. Literature of Pharmacy and Materia Medica. VII. Of Vital Statistics. VIII. Of Life Assurances. IX. And of Introductory Lectures.

He was interrupted at eleven for the regular order of business, which was the lecture of Dr. Brown-Séquard, on the Treatment of Functional and Organic Diseases of the Nerves. We hope to give our readers a detailed report of this very interesting lecture in a future number.

On motion of Dr. Raphael, of N. Y., the thanks of the Association were tendered to Dr. Brown-Séquard for his interesting, able, and eminently practical lecture, and he was requested to furnish an abstract for publication.

Dr. C. A. Lee then resumed the reading of his report.

After this had continued for some time, on motion of Dr. Toner, the further reading was discontinued, and the paper referred to the Committee on Publication.

Dr. Gross, Chairman of Committee on Medical Education, reported that he had not prepared a report, and asked that the Committee be discharged, which was granted.

REPORT OF PRIZE COMMITTEE.

Dr. E. Eliot, Secretary of the Committee on Prize Essays, read the report of that Committee.

On breaking the seals, Dr. W. F. Thoms, of New York city, was ascertained to be the author of the "Essay on Health in Cities," etc., and was entitled to the first prize, and Dr. S. R Percy of N. Y., on "Digitaline," etc., to the second.

On motion, the paper on Angular Curvature of the Spine was referred to the Section on Surgery.

The report of the Committee on Medical Ethics having been offered, it was made the special business for 9.30 on Thursday.

Dr. MARSDEN, of Canada, having been announced as desirous of making some remarks on Cholera,

On motion, it was agreed that he should follow immediately after the report on Medical Ethics.

Dr. COHEN offered a paper on Paralysis of the Vocal Chords and Aphonia, etc. Referred to the Section on Surgery.

Dr. H. R. Storer offered a paper on the "Clamp Shield," an instrument designed to lessen the dangers of extirpation of the uterus by abdominal section.

Dr. BOZEMAN, of Ala., was introduced to the Association, and on motion of Dr. Holton, he was made the member of the Committee on Nominations for Alabama.

Dr. Askew offered the following resolution on the death of Dr. Cowper, which was unanimously adopted:

"*Whereas*, We have heard with profound regret of the death of our deservedly esteemed friend and associate, James Cowper, M.D., of Delaware, late Vice-President, and one of the founders of the National Medical Association; and whereas, we desire to express our high appreciation of his worth as a man, and valuable and untiring energy in the cause of medical science; mild, modest, and unassuming, of devoted piety, he was firm, constant, and reliable; a strict adherent to the ethics of the profession, he occupied a front rank, and died beloved, respected, and lamented by all who knew him,

"*Resolved*, That in the death of Dr. James Cowper we have lost a friend and brother, and that we sincerely and deeply condole with his sorrow-stricken widow and family, and that the Secretary be authorized to forward a certified copy of these resolutions to his family."

Dr. TONER, of D. C., offered the following resolution, which was adopted:

"*Resolved*, That instead of yearly reprinting the list of members of the American Medical Association with the Transactions of the same, the Secretary be instructed to prepare and have printed in pamphlet form, a triennial alphabetical catalogue, containing the Constitution of the Association, and a list of members with their full names, designating their residences, the year of their admission, arrearage of yearly dues, the offices they may have held in this body, and in case of death or resignation, the year, and distribute the same among the contributing members."

On motion, the resolution was referred to Committee on Publication.

Dr. J. C. HUGHES, of Iowa, offered a paper on Lithotomy, which was referred to Section on Surgery.

Dr. TAYLOR, of Iowa, introduced a resolution for the appointment by the President of the Association of a member from each State, to memorialize Congress for an appropriation to publish the reports and documents of the Surgeon-General of the United States.

Dr. PALLEN recommended that the reports and documents of the like character connected with the rebel army, be also referred to the same committee for access to the same. Dr. Pallen, after some discussion, withdrew his amendment.

The original motion was carried.

It was then moved that the President announce said Committee on Thursday morning.

The meeting then adjourned.

SECOND EVENING.—SOIREES AT PRIVATE RESIDENCES.

The evening was occupied by the members of the Association in responding to the kind invitations of the physicians of Baltimore to soirées at their respective residences. The houses of Drs. C. C. Cox, Bond, Surgeon Simpson, U.S.A., Professor N. R. Smith, and others, were thrown open. The entertainments were of such a character as reflected great credit upon the taste and hospitality of the gentlemen concerned.

THIRD DAY.—MAY 3.

The Association was called to order at 9 A.M. by the President, after which, the announcement of the members of the Committee to memorialize Congress on the publication of the surgical history of the war, was made.

Dr. C. C. Cox, of the Committee on Necrology, reported progress, and on motion of Dr. Hibbard, permission was given the reporter to send the report when ready to the Committee on Publication.

THE DEATH OF PROFESSOR JOSEPH M. SMITH, OF NEW YORK

Dr. ALFRED C. POST offered the following, which was unanimously adopted:

"*Resolved*, That the Association has heard with sincere regret of the death of its late distinguished member, JOSEPH M. SMITH, M.D., of New York:

"*Resolved*, That we cherish his memory as that of a learned and skilful cultivator of medical science, an able and successful teacher and writer, an upright and honorable man, and a patriotic and public-spirited citizen.

"*Resolved*, That the Secretary communicate to the family of the deceased, an expression of our sympathy with them in their bereavement."

Dr. C. A. LEE arose to speak to these resolutions, which he did with much feeling. He hardly thought that it was necessary to say anything in regard to the life or character of such an excellent and well beloved man, but as he had been intimately acquainted with him for over thirty years, he did not think it out of place for him to say a few words. After referring in an appropriate manner to his acquaintance with the deceased, he remarked "that a more pure, upright, and conscientious man I never knew, particularly with reference to his intercourse with medical men. When I think of the great loss we have sustained in him, I am at a loss to express myself."

Dr. J. S. KING of Natchez, Mississippi, forwarded a communication to the Association, stating that he was engaged in the compilation of the mortuary and similar statistics of the principal cities and towns of the country, and requesting that physicians would transmit to him such information upon those subjects as they could gather in their respective localities.

The SECRETARY read a communication from the Dubuque (Iowa) Medical Society, requesting the erasure of the name of Dr. Asa Horr.

On motion of Dr. JEWELL, the request was granted.

Dr. MAYBURY, on behalf of the Committee on Publication, to whom Dr. Toner's resolutions were referred, reported the following as a substitute, which on motion was adopted:

"*Resolved*, That instead of yearly reprinting the list of members of the American Medical Association, the Committee on Publication be instructed to prepare and print with the Transactions, an alphabetical catalogue triennially, containing a complete list of the permanent members, with their names in full, designating their residences, the year of their admission, the offices they may have held in the Association, and in case of death or resignation, the date thereof."

Dr. MAYBURY also presented the following, which, on motion, was referred to the Committee on Ethics.

"*Whereas*, Medical organizations, such as National, State, and County Societies, are believed to be absolutely necessary to preserve the honor of the medical profession, and to keep alive social and fraternal feelings among the members thereof, as well as an important means of promoting medical knowledge and elevating the character of the profession, therefore

"*Resolved*, That it is with sincere regret that we, the members of the Montgomery County Medical Society of Pennsylvania, learn that some honorable members of the Faculties of our medical colleges in Philadelphia and elsewhere, have kept aloof from the County Societies on which rest both State and National organizations, thus ranging themselves on the side of those whose unprofessional conduct or low standard of medical attainment, or disregard of medical etiquette, prohibits them from membership in those societies.

"*Resolved*, That as graduates of the University of Pennsylvania, Jefferson Medical College, and Pennsylvania Medical College, we have a high regard for the teachers of those institutions, and feel that they owe it to the profession and to our Alma Maters to give their hearty support to medical organizations in general, and especially to the County and State Medical societies.

"*Resolved*, That although Colleges are entitled to representation in the American Medical Association by one or more of their Professors, we are decidedly opposed to any College or any other medical organization being represented by a Professor who is not a member of a County Society.

"*Resolved*, That the Corresponding Secretary of this Society be instructed to report these proceedings to the Philadelphia County Medical Society, and that our delegate be charged to lay them before the American Medical Association at the coming meeting to be held in Baltimore on the first day of May next, as well as before the Medical Society of the State of Pennsylvania at its next meeting, to be held at Kingston in Luzerne County, on the thirteenth day of June ensuing."

W. P. ROBINSON,
President Montgomery Co. Med. Soc., State of Pennsylvania.
E. SMYSER,
Corresponding Secretary.

THE REPORT OF COMMITTEE ON ETHICS.—SPECIALTIES IN MEDICINE.

Dr. WORTHINGTON HOOKER offered the majority report, and in the main took the ground adverse to exclusive specialties. He divided up the subject into exclusive and partial specialties. In reference to exclusive specialism, he maintained that local affections were apt to be unduly estimated, to the exclusion, perhaps, of other parts of the system that were of more importance in the production of a particular disease; that diseases cured by a specialty are magnified in their importance; that specialists too frequently undervalue the treatment of diseases by the general practitioner; that there is a temptation to employ undue measures to obtain notoriety; and that he is further tempted to charge unduly large fees. The field of medical practice were so large that the profession was always willing to seek advice from those who had devoted attention to particular subjects; but this should not encourage exclusive specialism. The specialty should be a natural outgrowth from the general practice, and should never be separated from it. If this were so, a full, frank, and free intercourse would be had between the specialists and general practitioners. The means availed of by the specialties to bring this fact before the public should be ordinary, and not extraordinary. There should be neither advertisements nor puffs in the newspapers. The professor in a school has been chosen for it by those who are competent to discuss his merits for that position, if he were by himself to place before the public the fact that he is specially skilled in the branch taught by him, he would come under this censure.

The report was well drawn up, and claimed the undivided attention of the members.

Dr. KENNEDY, of New York, followed with a minority report, stating that he would read it in the absence of the writer. The writer believes that the whole tendency in every department of science is towards specialties. Science has been advanced during the last century by this course. Recently this tendency has shown itself in the persons of certain practitioners who resign all general practice, and confine themselves to the specific department they have chosen. No association can object to the advertisement in such cases, unless it is of a mountebank character. The report was signed by H. J. Bowditch.

The subject was then discussed by Drs. H. R. Storer of Boston, Worthington Hooker of New Haven, and others; but the hour of eleven having arrived, Dr. W. Marsden of Quebec was introduced, and proceeded to address the Convention on the subject of cholera connected with Quarantine.

CHOLERA AND QUARANTINE.

Dr. MARSDEN, of Quebec, according to previous appointment, made some remarks upon Cholera. He commenced by stating his belief in the communicability of cholera, and the efficiency of a rigid quarantine. He had witnessed the first case that had occurred on the American continent, and since that time had given much attention to the study of the disease. He was now convinced that every case of cholera could be traced to infection, and that the proper soil for the propagation of the disease was to be found in filth and the neglect of the ordinary sanitary precautions. He believed that all clothing from patients suffering from the disease should be destroyed, and thus be prevented from spreading the disease. He believed that isolation would prevent the appearance of the disease in any community, and related an instance in point which had made such a strong impression upon him that he was caused to think first of his plan of quarantine. It seems that a schoolmistress, in a locality where cholera threatened to make its appearance, consulted the doctor on the best course to pursue. He advised her, as soon as the disease should appear, to isolate the school from the rest of the town, by closing her gates and doors. This was done, and not a single case of cholera occurred within the walls. Dr. Marsden next gave the members a detailed account of his system of quarantine. As all of our readers may not be familiar with this plan, we will quote from his printed report which he gave us:

"1. The Cholera Quarantine Station shall be divided into three separate and distinct sections or departments.

"2. Each of these three sections or departments shall be isolated and separated from the others by a *cordon* or portion of neutral ground of not less than one hundred feet wide.

"*a.* One of these sections or departments shall be appropriated to the use of the sick, and shall be the Hospital Department.

"*b.* The next or central section or department shall be devoted to the use of passengers not having had cholera, but from infected vessels.

"*c.* And the third or healthy section or department shall be appropriated to the use of the healthy, who have been removed from the central department, after having performed quarantine there.

"*A.* In the first section or department there shall be three separate and distinct hospitals, besides a convalescent shed or hospital.

"*a.* The one for confirmed cases of cholera to be called the CHOLERA HOSPITAL.

"*b.* Another for cases of choleraic diarrhœa, or other

premonitory symptoms of cholera, to be called the Hospital for Cholerine.

"*c.* The third for all other diseases not cholera, or cholerine, but coming from on board infected vessels, or vessels having had cases of cholera on board, to be called the General Hospital.

"*B.* The next or central section or department, shall be the primary quarantine department, and shall be appropriated to all persons who are not sick, but come from vessels having had cholera on board, and wherein every case on landing shall undergo inspection, washing, cleansing, and purifying both of persons and personal effects. There a quarantine of four days shall be performed, at the end of which period of time all such persons as continue in sound health shall be removed to the Final Quarantine Department, and any that may fall sick or be threatened with sickness during the four days of probation, shall, as soon as detected, be removed to the proper hospital, in the Hospital Department. There also the healthy inmates shall be removed daily to a new locality, thus occupying four different habitations during their sojourn.

"*C.* The third, or healthy department, shall be the Final Department, and shall be for all cases coming from the Primary Quarantine Department, after having been cleansed, washed, and disinfected, and after having undergone the *four days'* quarantine; and here a further quarantine of *six days* shall be performed (excepting cases coming from the convalescent hospital or shed, hereinafter provided for), making in all *ten days* of quarantine, when all persons continuing healthy shall be discharged from quarantine, and be removed from the station. If any premonitory symptoms or other cases of sickness occur in this department during the six days of quarantine, they shall, as soon as discovered, be removed to the proper hospital, in the Hospital Department.

"No communication shall take place with the Hospital Department, except through the central or Primary Quarantine Department, for which purpose a passage, unfrequented by the persons undergoing quarantine, shall be set apart and reserved."

Dr. Lee moved the thanks of the Association to Dr. Marsden for his interesting and practical address, and the request of the body that he furnish it with a digest of his communication.

Dr. Bond amended, that those papers accompanying the lecture be commended to the city authorities, and the authorities having such matters in charge throughout the country, for their action.

Dr. Jewell thought the matter should be further investigated, and moved its reference to the Section on Hygiene, to meet that afternoon.

The special business of the day was suspended to allow the Committee on Nominations to report.

THE OFFICERS FOR 1866–7.

President—H. F. Askew, Delaware.

Vice-Presidents—W. K. Bowling, Tennessee; J. C. Hughes, Iowa; H. J. Bowditch, Massachusetts; Thos. C. Brinsmade, New York.

Permanent Secretary—William B. Atkinson, Pennsylvania.

Treasurer—Casper Wistar, Pennsylvania.

Assistant Secretary—W. W. Dawson, Cincinnati.

Committee of Arrangements—Drs. John A. Murphy, James Graham, R. R. McIlvaine, J. P. Walker Unsicker, William T. Brown, William B. Done, Cincinnati.

Committee on Medical Education—Drs. T. D. Gross, D. F. Condie, John Bell, H. J. Bigelow, Charles A. Pope.

Committee on Prize Essays—Drs. Francis Donelson, Maryland; Simpson, U.S.A.; C. C. Cox, Warren, Van Bibber.

Committee on Publication—Continued.

Committee on Medical Literature—Drs. A. C. Post, Jas. Anderson, H. D. Noyes, T. G. Thomas, Stephen Smith, all of New York.

Committee on American Medical Necrology—Dr. Wood, Delaware, substituted for Dr. Cooper; Jno. L. Callender, in place of Dr. Bowling; Jno. Blaine, in place of Wm. Pearson. The following were added: Drs. R. D. Arnold, Georgia; Lopez, Alabama; G. Dowell, Texas.

Committee on Climatology—H. Jones, in place of C. L. Allen, Vermont. The following were added to the committee: Drs. U. Harris, Georgia; G. Engelman, Missouri; R. Miller, Alabama; Fenner, Louisiana; G. Dowell, Texas.

All special committees are to be selected by the sections to which the subjects relate.

THE NEXT PLACE OF MEETING.

The place recommended for the next annual meeting of the convention is Cincinnati, Ohio, on the first Tuesday in May.

On motion of Dr. Ordway, of Boston, the report of the committee was adopted.

On motion, the Association went into a committee of the whole to discuss the resolution offered by Dr. Hibbard, having reference to extending the time for the course of study in the different medical colleges.

The whole matter was earnestly discussed by Drs. D. H. Storer, Worthington Hooker, Wright, of Ohio, Davis, of Ill., and others, and resulted in the passage of the following resolution, offered by the last gentleman:

"*Resolved*, That the Association most earnestly request the medical colleges of the country to hold a convention for thoroughly revising the whole system of medical college instruction for the purpose of establishing more uniformity of time, and a more systematic course of instruction for the whole."

The report of the Committee of the Whole was adopted, and a committee consisting of Drs. Davis, W. Hooker, S. D. Gross, Wright, and Shattuck, was appointed.

Dr. C. C. Cox read the report "On Rank in the Army," which was referred to the Committee on Publication.

Dr. Cox then offered the following, which was adopted:

"*Resolved*, That the President of this Association bring before the notice of the Military Committees of both Houses of Congress, at as early a period as possible, the present status of medical men in the military service of the U. S., and urge upon them that in the army medical bills, under consideration of Congress, the interests of the medical profession shall be so regarded that the medical staff in the service shall, numerically considered, receive the same rank and command as officers in other staffs of the army are justly entitled to."

The committee appointed to act on the foregoing resolution were Drs. D. H. Storer, C. C. Cox, Antisell, Johnson, and Allen.

On motion of Dr. Cox, the following members, by invitation, were elected: W. D. Stewart, Va.; W. S. Forward, H. W. Stump, and J. L. Chaplain.

A committee was appointed on the subject of Fracture of the Spine, of which Dr. Brown-Séquard was made chairman.

On motion, Drs. Post, Antisell, and Atlee were added to complete the Committee on Medical Ethics.

SPECIALTIES AGAIN.

On motion, the report of the Committee on Ethics, which had been laid on the table, was called up.

On motion of Dr. TONER, the resolution attached to the minority report was omitted, and the reports were both adopted.

A motion to reconsider next prevailed, and the resolution was added to the minority report referred as before.

Dr. HOMBERGER, of N. Y., made a request to offer a personal explanation, which after considerable discussion, confusion, and sensational speaking, was granted.

On motion of Dr. SAYRE it was agreed to hold an adjourned meeting at 5 P.M., to discuss the subject of cholera.

A communication from Dr. McGEE, "On Periosteal Flap Amputations," and one from Dr. Elsberg, N. Y., "On Diagnosis of Diseases of the Larynx," received, and both referred to the Section on Surgery.

The meeting then adjourned until 5 P.M.

THIRD DAY—AFTERNOON SESSION, MAY 4.

At five P.M., according to previous adjournment, the Association met, and after being called to order, resolved itself into a Committee of the Whole, choosing Dr. Davis as Chairman.

The subject for discussion, as previously announced, was

CHOLERA.

Dr. SAYRE, of New York, opened the discussion. He considered that the disease could not reach here unless it was brought here; that it could not be generated here. It multiplies its ravages when filth and uncleanliness abound, and is generated in a sandy, level country, beneath a temperature of 128 degrees. There the decomposing animal and vegetable substances originate this peculiar poison. He believed that it accompanied the individual, and that it did not travel by atmospheric power. He thought that the government was responsible for permitting the disease to get into the land. A rigid, proper quarantine, universally adopted by the General Government in combination with the British Provinces, would, in his opinion, prevent its admission to our continent. We had no quarantine, rightly considered. The disease in 1849 did not originate in Baxter street, New York, but took its origin from an infected person who escaped from quarantine. The cabin passengers escape because the disease has not travelled 200 feet nor ten feet from the steerage to the cabin. He remarked that he did not believe in mysteries, but wished to understand facts in his own way. If the valuable information that he had obtained from Dr. Marsden were put into practical application by the General Government he believed that millions of money and millions of lives would be saved.

Dr. LINTON protested against the doctrines advanced that morning and evening. We had medical journals through which we could discuss this subject a long time before the cholera would get here, and a long time before quarantine could prevent its getting here. "Who can believe that cholera could have been prevented from coming here in 1849? I do not believe it is any more contagious than intermittent fever. I am certain that nine-tenths of the physicians of this country are convinced of this fact. I say to the citizens of New York, Baltimore, and Canada, you may have no fears of the cholera. If it comes it will arise in your midst. Cholera is not a disease (!!)" He did not believe that there was any truth in the doctrine of contagion. "Cholera breaks out in ships after they are six weeks at sea. I saw a case in St. Louis two months ago. Where did the Asiatics get it from?"

Dr. BELL, of Brooklyn, thought the facts of Dr. Marsden inconsistent with the results of observation. Dr. M. had traced it first from a brig in Liverpool. He did not say that cholera existed in Liverpool at the time. Dr. B. believed cholera can be traced to various places other than Asia. "If cholera is contagious, it takes various roundabout ways of making short journeys. It took an exceedingly roundabout way to the principal cities of Europe. Of the present epidemic, it is said the Mecca pilgrims first had cholera. The evidences I have collected are against strict quarantine. The passengers of the Atalanta were detained at quarantine; no cases occurred among the well passengers after they left the ship. Of all the things likely to originate cholera, none are equal to a crowded, filthy ship. None of the passengers or things of the Atalanta were taken to Ward's Hospital. I would protest against the endorsement of any restrictions against persons advised by Dr. Marsden. The detention of well persons can never protect us against any disease. Our protection is in our clean houses, for cholera often leaps over healthy residences. The action of the health officers at the New York quarantine has been fatal to well persons, and has tended to ward off investigation of the places where cholera originated."

Dr. JOHN L. ATLEE, of Pa., said that it was difficult to know the facts in large commercial cities. "There are a thousand avenues to such cities as New York and Boston; but in the inland districts we are more likely to reach a better observation of facts. In 1832 I was in the midst of cholera at Lancaster County Hospital, Pennsylvania. I believed that cholera and yellow fever were diseases independent of any idiomiasmatic conditions of the atmosphere. In July or August, 1854, a certain peculiar condition of the air existed. The water of the Susquehanna was very low, and the water of the basin very filthy, yet there was no cholera. There were, however, some cases of bilious and intermittent fever. One day a car of emigrants came from Philadelphia to Columbia; two or three of the passengers were ill, and were put upon the platform. Four gentlemen seeing them there at the point of death, conveyed them to a shed. In the next twenty-four or forty-eight hours not one of them was living. In two or three days the cholera prevailed in Columbia. In the Lancaster County Hospital the winds were from the south. We had no cholera. A few days after the cholera broke out in Columbia, an emigrant reached there afflicted with cholerine. Shortly after two or three cases of cholera existed. The same train conveyed the cholera to Pittsburgh. Passengers came to the vicinity of Lancaster at a place called Paradise. Their effects were sent to Lancaster in a high and healthy location. The relative who washed the clothes died of cholera. It is a contagious disease. Why did it not spread? Why did not small-pox spread? There is an atmospheric constitution favorable to the development of disease. The result of observations in Sweden was that it had been conveyed there by the clothes of sailors. I think Dr. Marsden is right and Dr. Sayre is right, and our friends in Philadelphia must come to the same conclusion if they wish to preserve that metropolis from the ravages of the cholera."

Dr. SAYRE said the quarantine law of New York, as now enforced, is a disgrace to civilization. Dr. Carnochan, himself, and others saw the cases on Ward's Island, and they all came to the conclusion that they were not cases of cholera.

Dr. BELL remarked that Dr. Geo. Ford insisted that the Ward's Island cases he treated were those of cholera.

Dr. SAYRE then quoted from Dr. Ford's official statement in the annual report of the Commissioners of Emigration, in which he (Dr. F.) stated on page 52, that

those "twenty-seven deaths were caused by *diarrhœa* and dysentery." This was the *official* statement of Dr. Ford.

Dr. MARSDEN said that cholera followed human travel. He adduced other facts to demonstrate its contagious character. It is infectious in person and personal effects. He urged the necessity of guarding against any communication between the infected and the well. Equanimity, cleanliness, and temperance were three great adjuncts to the quarantine.

Dr. JEWELL, of Pa., said: "I have been charged with disseminating cholera. I have done all I could to prevent its entrance to Philadelphia. Cleanliness and ventilation will do much to that end. We have been engaged at that during the past winter. I do not believe in quarantining healthy people. That would be disseminating the disease by giving it to the well persons on vessels where cholera existed. We had the epidemic in the summer of 1849 in Philadelphia. It began in four different portions of the city. The first case was at Richmond, the second at Eighth and Spring Garden streets, the third in Moyamensing. These were all in the centre of the city, except at Richmond, and remote from the Delaware. The filth produced the disease in Richmond and along the Delaware. In 1832 the first case was on the Schuylkill, in a canal boat that came down from the upland country. There had been no foreign arrival in Philadelphia. It came from a poisoned atmosphere. In 1849 no flies were living. In Wheeling the birds died. The doctrine of contagion is dangerous, and will deprive the sick of assistance. Small-pox does spread, and if we had not vaccination it would spread more than it does. Contagion and infection are distinct. Contagion is the principle communicating the disease from one person to another. It is not so with cholera. There were no cases of contagion in 1832 or 1849. No vessels arrived with cholera on board. They may have arrived after the disease appeared. I am sorry the resolution was introduced. Next year we will be better able to test the value of Dr. Marsden's information. The poison of cholera will increase rapidly by contact with filth. It is only by purification of the city that cholera can be prevented."

Dr LEE followed with some brief remarks sustaining the views of Dr. Marsden, and maintaining that it was contagious under certain circumstances. Certain neighborhoods of a very filthy character were not attacked until emigrants came there.

The Committee of the Whole rose, and the Association adjourned without further action.

THIRD EVENING, MAY 3.—ENTERTAINMENT BY THE CORPORATE AUTHORITIES.

The corporate authorities of the city gave an entertainment to the members this evening, at which were present all the notabilities of the city, including the principal officers and members of the City Councils. The entertainment was prepared in the most generous and munificent manner, and reflected infinite credit on the donors. Between four and five hundred gentlemen were present. The supper was called at nine o'clock. A band of music, stationed in the gallery, initiated the occasion with an appropriate air, and at intervals in the course of the evening performed all the national hymns and songs. After discussing the substantials of the bill of fare, the customary toasts were given by Dr. J. Faris Moore, toast-master, and suitably and eloquently responded to by gentlemen of the municipal government of the city, and the officers and members of the Association, the attention and laudations of the great assemblage being specially directed to the eloquent response made by Dr. N. Pinckney to the toast, "The navy of the United States and its medical corps." Other toasts were equally well received, and the interest of the supper was sustained until a late hour in the evening.

FOURTH DAY.—MAY 4.

The Association was called to order at the appointed time, 9 A.M., by the President. After which, the Minutes of the previous sessions were read by the Permanent Secretary, Dr. W. B. Atkinson, of Philadelphia.

Dr. Cox was, on motion, accredited as a delegate to the Foreign Societies.

Dr. GARRISH, of N. Y., offered the following, which was adopted:

Resolved, That all the members of this Association urge upon the Legislatures of the various States the great importance of making it compulsory that all marriages, births, and deaths be registered.

MEDICAL RANK IN THE NAVY.

The Naval Committee appointed at the last meeting of the National Medical Association having failed to report upon the subject of naval medical rank, it was moved by Dr. Cox that Surgeons Wm. M. Wood, Ninian Pinckney, and David Harlan, U. S. N., be appointed a committee to report upon this subject at the next meeting of the Association. Adopted.

Various amendments were next brought up and laid upon the table.

The reports of the various sections were then in turn called for, and adopted. They will be found in another place under appropriate headings.

Dr. HOLTON, of Vt., offered the following, which was unanimously adopted:

"*Whereas*, The author of the Essay, Dr. H. R. Storer, to whom the prize of $100 from this Association was awarded in 1865, refused to receive the amount thus awarded, consequently increasing the resources of the Association to that amount; therefore

"*Resolved*, That the thanks of this Association are hereby tendered to Dr. H. R. Storer for this display of liberality."

The Committee on Ethics appointed to report on the resolutions of the Montgomery Medical Society, recommended a reference of the whole matter to the Medical Society of that State.

Dr. HOLTON offered the following, which was lost:

"*Resolved*, That at the future meetings of this Association there shall be held two general sessions, one in the morning and one in the evening, unless otherwise ordered."

Dr. KING, of Pittsburgh, offered the following:

"*Resolved*, That this Association, approving of the system of quarantine proposed by Dr. Marsden, of Canada, as the most effectual means for preventing the introduction of cholera into this country, do earnestly recommend the propriety of its adoption at all our ports of entry, to the favorable consideration of Congress."

The House then on motion, after a little discussion, went into a Committee of the Whole, Dr. Davis being Chairman.

Dr. BELL, of Brooklyn, was granted the privilege of making a personal explanation of his statements in reference to cases of cholera on Ward's Island, and although he persisted in his original assertion, the Chair declared that the whole matter was, he presumed, well understood by the Association, there being only a different scientific opinion entertained by two different parties.

The resolution of Dr. King was then taken up, and after much discussion,

Dr. J. H. BURGE, of Brooklyn, offered the following,

which, after eliciting many remarks from Drs. Horton, Storer, Post, Lee, Pinckney (U.S.N.), Marsden, and Dr. J. Anderson (N. Y.), was on motion laid on the table. The following is the resolution:

"*Resolved*, That this Association appoint a Committee of Ten to memorialize Congress to the following effect: That whereas, in the opinion of many eminent physicians, the system of quarantine recommended by Dr. Marsden, of Canada, for protecting our country from Asiatic cholera, would prove effective; therefore, *Resolved*, that we earnestly petition the government of the United States to make an immediate and ample appropriation, and take all other necessary measures to test the utility of said system."

The Committee of the Whole rose and reported accordingly.

The President resumed his seat.

Dr. Cox moved that Dr. J. C. Tucker, of Nevada, be a member by invitation. Adopted.

Dr. Stokes offered the following as the report of the section on Psychology, which was accepted and referred:

"The section on Psychology unite in requesting that a committee be appointed to make a report at the next annual meeting on Insanity, and ask that Dr. J. Ray, of Providence, R. I.; Clement C. Walker, Massachusetts; A. B. Cabaniss, Mississippi; W. S. Chiply, Kentucky; John Fonerdin, Maryland, be appointed said Committee.

Clement C. Walker, *Chairman.*
Wm. H. Stokes, *Secretary.*"

The report of the Committee of the Whole in reference to the question of quarantine was then adopted by the Association.

DEATH OF PROF. D. L. MAGUGIN, OF IOWA.

Dr. Taylor, of Iowa, presented the following:

"*Whereas*, After a long and laborious life devoted to the practice of medical art and promotion of the interests of medical science, Dr. D. L. Magugin, of Iowa, has been called to the final rest of all good men:

"*Resolved*, That the Association, while deeply regretting the loss they have sustained, will ever keep alive the memory of his many virtues and professional worth, and commend the example of his untiring devotion to our common cause.

"*Resolved*, That a copy of these resolutions be furnished his family with sincere condolence."

Dr. Garrish, of New York:

"*Resolved*, That the members of this Association tender their heartfelt thanks to our professional brethren of Baltimore for the liberal, cordial, and satisfactory manner in which they have entertained us."

Dr. H. R. Storer offered his report as Delegate to the last meeting of Superintendents of American Institutions for the Insane, and presented the following for adoption:

"*Resolved*, That the Association recommend to the several medical and law schools of the country, the establishment of an independent chair of Medical Jurisprudence, to be filled if possible by teachers who have studied both law and medicine; attendance upon one full course of lectures from whom shall be deemed necessary before the medical degree is conferred.

"*Resolved*, That while this Association regrets that the Association of Superintendents of American Asylums for the Insane has not yet thought fit to unite itself more closely with the representative body of American physicians, it still is of opinion that such union is for their mutual and reciprocal advantage, and that it ought to be effected without further delay."

On motion, the above was adopted.

After the transaction of business of minor importance, the Association adjourned *sine die.*

The Meetings of the Sections.

SECTION ON PRACTICAL MEDICINE AND OBSTETRICS.

DISCUSSION ON DIPHTHERIA.

The section was organized by the appointment of Dr. Lake J. Tefft, of New York, Chairman, and Dr. W. B. Bibbins, of New York, Secretary.

Dr. H. D. Holton, of Putney, Vermont, Chairman of the Committee on Diphtheria, as it had prevailed in the United States, made a report by reading an elaborate and interesting paper. He gave a history of the disease from its first appearance in this country, more than a century since. He insisted that diphtheria should not be confounded with follicular tonsilitis and kindred affections; in fact, nothing should be dignified with the name that did not present the characteristic exudation, with swelling of the cervical glands, etc. Neither should it be confounded with scarlatina or croup. Tables were presented showing the fatal months, the proportion of deaths at various ages of the three diseases. The disease was divided into diphtheria simplex, diphtheria maligna or gangrenosa, and tracheal diphtheria. He entered at some length into the discussion of the sequelæ, stating that they were paralysis, rheumatism, and general cachexia.

After discussing the various plans of treatment, he divided it into local and general. Such mild cathartics should be used as the case seemed to require, although nothing like active purgation should be indulged in. Chlorate potassa should be given pulverized with an equal amount of sugar, a little placed in the mouth, and allowed to run down the throat, that the local as well as the constitutional effect might be obtained.

Sulph. quinin. and tr. ferri chloridi should be used as occasion required; also alcoholic liquors, either alone or combined with cinchona bark; wine whey, milk punch, and beef-tea were to be used to support the patient when a nourishing diet could not be taken.

The local applications should be such as would prevent the absorption of fluid portions of the exudation. For this purpose persulphatum ferri was recommended; also the following: ℞. Tr. ferri chloridi, chlorat. potassæ ãã ʒj; glycerine pure, ʒ ij. Misce. Either of these to be carefully applied with a soft brush. Externally, an infusion of hops in lye of wood ashes would be found the best for any hot fomentation.

The following deductions were made: 1st. That diphtheria has occurred as an epidemic from time to time from the first settlement of this country; 2d. That it is a distinct disease, on no account to be confounded with scarlatina or croup; 3d. That it is particularly a disease of childhood, athough it exempts no age; 4th. That it is communicable to that degree that it is the duty of every physician to separate the infected from those that are well, particularly in children; 5th. That it is a disease primarily affecting the blood, consequently the treatment to be effective must be not local but general, and of such a nature as to eradicate or neutralize the poison; such local treatment should, however, be used as will prevent the absorption of fluid portions of the exudation; 6th. That when the exudation has invaded the trachea, the only hope of saving the patient is in tracheotomy.

On motion of Dr. Ellsworth Eliot, of N. Y., the report was referred to the Committee on Publication.

Dr. King wished to take exception to the remark made in this paper that when the membrane is thrown off from the trachea the patient will almost always

get well. He had seen two cases, one a man and the other a child, in which the membrane had been thrown off and both had died. He could not believe that the cast-off membranes were ever re-absorbed. He stated that he had ceased to use local applications for anything more than their antiseptic effects; and for this purpose he thought that the solution of common salt was as good as anything else.

Dr. Gallagher, of Pittsburgh, Pa., expressed himself much pleased with the report. He regretted, however, that the author had made no reference to the use of alum as a local application. He had used that remedy with the happiest effects, and had more confidence in it than all the others. He had used also with great satisfaction the ordinary "hard cider," with a view of assisting the elimination of the morbid materials by the kidneys.

Dr. Worthington Hooker, of New Haven, stated that there was a great tendency in the profession to run into extremes in reference to treatment. He was not disposed to think that any disease could be successfully treated by following any one plan to the exclusion of others. The really rational plan was to follow all the indications in the particular case as they might arise. There were many marked distinctions between croup and diphtheria, but he chose only to refer to the want of that severe constitutional disturbance in the former which is never absent in the latter disease.

Dr. McCollum, of Vermont, stated he had seen 200 cases of the disease in his county within the last five years. He had seen three or four cases recover after the membrane had been cast off. He never used gargles except as disinfectants. As regards ice, he had noticed benefit from its use in a great many cases. He had also been in the habit of allowing his patients to inhale the vapor of acetic acid, and with marked benefit.

Dr. Gross, of Pittsburgh, stated that he had had a large experience in the treatment of diphtheria in his district, and had come to the conclusion that the best means of treatment consisted, first in the use of calomel as an antiphlogistic, followed by the very free use of chlorate of potash. He had seen 400 or 500 cases of the disease since he instituted this plan of treatment, but had not met with a single fatal case. He also, in conjunction with the foregoing remedies, made use of the solution of nitrate of silver (20 grains to the ounce) as a local application, as well as saturated solutions of alum and lemon-juice on crushed ice.

Dr. Bibbins, of N. Y., stated that some time since the question was asked him by Prof. A. Clark—What was the number of cases of diphtheria which he had met with in dispensary practice? Dr. Bibbins, before he was prepared to answer such a question, wished to know from Dr. Clark what he understood to be true diphtheria—whether the essential symptoms of the disease were considered to be adenitis, false membrane, fever, and depression of the vital powers. "Of course," replied Dr. Clark, Dr. A. Jacobi, who had studied this subject very thoroughly, has published the fact that these symptoms are always essential to the disease. A certain proportion of cases must be distributed to each individual; and such being the fact, the could not but believe that when gentlemen report such a large number of cases as occurring in their practice they do not take into account the necessary symptoms of diphtheria; that a great many report cases which they call diphtheria, which other practitioners are not willing to admit as such. He remarked that the average mortality of true cases of diphtheria among dispensary patients was thirty-three per cent., and did not suppose that under any treatment this mortality could be much decreased. Dr. A. Clark had reported the same rate of mortality. Dr. Bibbins was led to believe, from the cases which he had met with, that the tonic and supporting plan of treatment was the only reliable one.

Dr. Shumway, of N. Y., had used with great benefit, as local applications, the nitrate of silver stick, the chlorate of potash, and the chlorate of ammonia. He apprehended that the great difficulty with many patients that were convalescent was not that they did not get medicine enough, but that there was paralysis of the throat which prevented them from swallowing them. In those cases he had used nutritive injections into the stomach with very good results.

Dr. Davis, of Ill., spoke in this connexion of blood-poisoning in many diseases, diphtheria among the rest. He thought that there was yet a great deal to be learned with reference to the true pathology of these so-called blood diseases. The query had arisen with him whether diphtheria really depended primarily upon a poison in the blood, or whether the altered condition of the blood itself, instead of being primary, was itself a secondary consequence of a prior change in the properties of the organized tissues of the human body. He discussed this question at considerable length, showing the probability that there might be such a fundamental error in nutrition, as that assimilation or disassimilation was so interfered with that the blood was poisoned in consequence.

Dr. Hewitt remarked that he had great faith in the solvent power of both alum and chlorate of potash on the diphtheritic membrane. He had taken pieces of the membrane that had been separated, and had dissolved them entirely in solutions of these salts. His treatment was to take a glass tube, pass it back into the fauces, and inject one or other of the solutions directly against the affected parts.

Dr. McIntyre, of Concord, N. H., was of the opinion that if there was any error in nutrition, it was secondary to the formation of the membrane in the throat, which by obstruction to the respiration interfered with the proper oxidation of the blood. This he considered to be the starting-point of the constitutional trouble. For the purpose of aiding the system in the elimination of the poison in the later stages of the disease he had used colchicum seed, guaiac, and nitrate of potash, with much satisfaction.

Dr. Taylor, of Iowa, did not think that there was any good to be attained by suggesting this and that remedy for a disease which had existed in every section of the country; for different remedies must be used in different localities, and he thought the best guide for any general plan of treatment was to be found in a proper, thorough, and enlightened view of the pathology of the disease.

The meeting then adjourned.

SECOND SESSION.

Dr. Lake J. Tefft in the Chair.

The second meeting of the Section was held at the Dental College, corner of Hanover and Lombard streets, on Wednesday, May 2, 1866, at 3.45 P.M.

The minutes of the last meeting were read and approved.

Dr. Jas. J. Levick, of Philadelphia, read the "Report of the Special Committee on Spotted Fever."

On motion of Dr. Henry D. Holton, of Putney, Vt., the report was referred to the Committee on Publication, with a recommendation for its publication in the Transactions of the Association.

INHALATION OF NEBULIZED FLUIDS.

Dr. J. Solis Cohen, of Philadelphia, read a paper entitled "Remarks on the Inhalation of Nebulized Liquids, and their Topical Application to Inflamed and Ulcerated Surfaces."

The reader stated that his design was not so much to present a review of the knowledge of the profession on these topics, or to bring forward any of his peculiar views, as much as to give a resumé of the results thus far obtained from recent experience, with a view of eliciting upon a subsequent occasion a valuable paper on the whole subject of the Therapeutics of Inhalation, which should embody the experience of a number of observers, and furnish the profession with authoritative data for their general investigation, inasmuch as the literature on this subject, especially in this country, was very meagre and unsatisfactory.

The paper stated that the idea of treating diseases of the respiratory organs by inhalation, which should bring remedies directly in contact with diseased surfaces, was as old as the healing art itself; for what was more natural than to imitate the entrance of the vivifying breath of life in its access to the economy? The records of classic Greece and Rome show that this principle was taken advantage of in the inhalation of volatile substances, and in the residence of patients upon the seashore, and in the neighborhood of volcanoes. This method of treatment fell into disuse, and was again resorted to many times, and had fallen into permanent neglect for a long period, until the discoveries of oxygen leading to further chemical research, and the promulgation of the exhilarating effects following inhalation of the nitrous oxide gas, again directed attention to the subject of inhalation as a remedial agent. Then the ammoniacal exhalations from cattle yards, stables, etc., became largely employed in many affections, until too extended empirical application to all the ills of life meeting with failure, led the whole system into disuse, even for these affections for which it was originally intended. The discoveries of the properties of chlorine, iodine, etc., of the effects of the smoking of opium among the Chinese, led to the employment of similar substances; and the whole series of narcotics, resins, and all substances producing vapor became employed in this manner.

Observations of the diseases affecting workers in minerals, metals, etc., and the post-mortem revelations of the scalpel, proving the entrance of particles of dust into the lungs, led to the therapeutic employment of powders by inhalation.

After some other general remarks of a similar nature, the paper went on to relate that within a few years a new method of presenting *liquid substances* for inhalation *as such*, had become much employed in Europe, and seemed to promise an extensive field of success in the treatment of the whole class of pectoral troubles.

Every one is familiar with the effect of a stream of water directed upon the side of a house, how a large portion of the volume of water is directed back in a shower of small streams, or coarse spray. In certain bathing establishments in Germany, many liquid applications are made on this principle to the surface of the body in the treatment of affections of special organs, and of the general system likewise. Streams of the medicated liquid are forced against metallic plates on the walls of the bathing apartments, and fall over the desired surfaces in this shower or coarse spray.

It having been noticed that amelioration of concomitant chest affections seemed to follow this exposure for other purposes, patients were sent to these establishments to respire the air thus impregnated. The beneficial results obtained at the Inhalatorium of Dr. Auphan, of Eaux-les-Bains, established in 1849, led to similar establishments elsewhere, until finally, Sales-Girons, who in connexion with Flubé, had in 1856 erected an inhalatorium at Pierre-fonds, conceived the idea of constructing on this principle a portable apparatus which could be employed by patients at their residences, and thus admit of much wider application. Sales-Girons exhibited an instrument of this kind to the Academy in 1858. His apparatus consisted of a condensing syringe, which forced a very fine stream of liquid against a convex metallic button, converting it in deflection into a very finely divided spray, having much the appearance of a dense fog or mist, the separate particles of which, suspended as they are for a time in the atmosphere, playing around much like the dust observed in a sunbeam, can be drawn into the lungs by inspiration.

The paper referred to several of these apparatus, especially the modification of the tubes of Bergson, and the employment of steam by Siegle, in lieu of the compressed air, and stated that experiments upon living animals proved the entrance of these particles into the air-cells; though for various reasons, the spray striking against many surfaces during its ingress, its dissipation into a much larger volume than could be received into the mouth, etc., but a small quantity of the liquid thus nebulized (the writer thought not more than twelve per cent.), could reach the smaller bronchial ramifications.

The writer thought that the application in this manner of liquid substances of known strength directly to the diseased surfaces would prove more prompt in effect, whether for good or ill, than when the entire current of the circulation became the vehicle of communication, perhaps affecting the general system when not desirable. The mucous membrane of the lungs is quick to absorb, secretes no chemical product to modify chemical medicines, and has no temporary ingesta to interfere with the direct action of remedial agents applied to it.

Although the results thus far obtained are far from being positive, and many of them are unsatisfactory and negative, still they are such as to justify careful research into this new method of medication.

Some conclusions were then given as the results of recorded experience; the results of the writer's personal experience and observations, and the results of extensive experiments, carefully conducted by Dr. J. M. Da Costa, at the Pennsylvania Hospital, as well as those obtained by the latter named gentleman in his private practice.

A few remarks followed as to the manner of preparing medicines for employment in this way, and their application when different parts of the air-passages were to be medicated.

Allusion was made to the employment of this system of nebulization for local applications to inflamed and ulcerated surfaces on the exterior of the body, and a certain distance within the various cavities, and an instrument devised for this purpose was exhibited, to demonstrate that in a second or two a layer of a caustic or other solution, many times more delicate than any film which could be deposited by the slightest touch of a hair pencil, could be directed upon an ulcerated or inflamed surface, whether of large or small surface. A continuous application of course can be kept up when desired, and in this connexion the method was recommended for the production of local anæsthesia for minor operations in surgery—a subject at present exciting a good deal of attention, and brought to the notice of the profession by Dr. B. W. Richardson, of London.

On motion, the paper was referred to the Committee

on Publication, for publication in the Transactions of the year; but at the request of the writer the motion was modified to call for the appointment of a special committee to report on the "Therapeutics of Inhalation" at the next annual meeting of the Association.

On motion, the paper was received.

Dr. J. E. Clawson, of Delaware, moved that the Section appoint a Special Committee on the Therapeutics of Inhalation, to consist of three members, and that the paper of Dr. J. S. Cohen, just read, be referred to that Committee. Carried.

The Chairman appointed as such Committee:

Drs. J. Solis Cohen, Philadelphia; Dr. J. M. Da Costa, Philadelphia; Dr. L. Elsberg, New York.

Adjourned.

THIRD SESSION.

The Section met at Concordia Hall, on Thursday, May 3, 1866, at 1.45 P.M.

In the absence of the Chairman, Dr. Ellsworth Eliot, of New York, was elected Chairman *pro tem.*

The minutes of the last meeting having been read and approved, the Section adjourned *sine die.*

SECTION ON MEDICAL JURISPRUDENCE PHYSIOLOGY, AND HYGIENE.

FIRST SESSION, MAY 1, 1866.

The session was organized at Concordia Hall, 3 P.M., May 1, by electing Dr. Wilson Jewell, of Pennsylvania, Chairman; and Dr. A. N. Bell, of N. Y., Secretary.

REPORT ON DISINFECTANTS.

The first paper called up was the Report on Disinfectants, which was read by Dr. E. M. Hunt, of New Jersey, chairman of the committee. On motion to refer it to the Committee on Publication, it was brought under discussion by Dr. T. Antisell, who, though he considered the report in many respects an able one, did not regard it sufficiently elaborate, particularly in the special utility of dry heat for the destruction of fungous organisms resulting from the exposed excreta of persons sick of the cholera. While he regarded the most scrupulous cleanliness and care in the removal as speedily as possible, of all accumulations of whatever kind from such persons; yet he thought that here disinfectants had their chief application, and that if means could be devised for the thorough application of heat to all such accumulations, the poisonous quality for the diffusion of the epidemic would be destroyed. Of ozone and other disinfectants dwelt upon by the committee, he thought them of much less importance; and that they occupied too large a space in the report, to the exclusion of that which he considered so much more useful.

Drs. Green, C. A. Lee, E. R. Squibb, Jas. Hibberd, took issue with Dr. Antisell as to the province of the committee in the report, regarding it in the main as sufficiently elaborate, and more strictly in accordance with what reports for the Transactions of the Association should be, than if it went into collateral subjects.

Drs. Hunt and Bell defended the report on the ground that it was necessarily a chief effort on the part of the committee to present a resumé of such facts as had from time to time been brought to notice in the history of disinfectants; and that it would not only be out of the province of the committee, but quite impossible, to report upon the special indications for the application of disinfectants to the various supposed causes of disease, such as the one presented by Dr. Antisell.

The motion to refer the paper to the Committee on publication was then put, and the paper was so referred.

On motion, it was voted that Dr. Antisell be requested to prepare a paper for the next Session of the Association, *On the Causes of Epidemics.*

INFLUENCE OF ELECTRICITY ON EPIDEMICS.

The next paper taken up was the report of a special committee on the Influence of Electricity on Epidemics, by Dr. Squire Littell, of Philadelphia.

This report was presented to the Section on Hygiene at the last session of the Association, but owing to its length was not all read. It was deferred for the time, and owing to the supposed absence of the author from the country, the paper was omitted from the Transactions. Members of the section present who had carefully examined the paper, spoke of it in high terms, and as being well worthy of publication in the Transactions. But as it was a long paper, and had already been examined, and in part at least discussed, they did not deem it worth while to again occupy the section with its consideration.

On motion, it was referred to the Committee on Publication. The section then adjourned.

SECOND SESSION, MAY 2.

THE USE OF PERMANGANATE OF POTASH.

Dr. B. F. Craig read a paper on the use of permanganate of potash for the purification of water, especially during the prevalence of epidemic cholera.

The points of the paper were presented by Drs. C. A. Lee and E. R. Squibb, namely, that the disinfecting agent in the use of the permanganate of potassa and allied substances—was ozone. According to the remarks of Dr. Squibb, the power of disinfecting substances generally, excepting some, such as charcoal, which are absorbents, can be measured in a certain degree by the facility with which they give out or abstract oxygen. The paper under discussion was defective, in that the author assumed that the organic matter present in nature is the cause of cholera; and also that he took no note of the deposit of carbonate of potassa that would take place even to a mischievous degree in the use of the remedy. Yet, upon the whole, the paper should be regarded as a contribution to the important subject of disinfectants. It was, on motion, voted to commend it to the Committee on Publication.

COMPULSORY VACCINATION.

Compulsory Vaccination was presented as a subject of discussion by Dr. A. N. Bell, chairman of the committee on that subject. While he regarded the literature of *vaccination for the profession* exhausted, he considered the field still large for the purposes of the committee, namely, the diffusion of information among the people; and his chief object in presenting the subject in this manner, instead of by formal report, was to elicit the expression of the Section as to the best means of diffusing information. In the Southern States, especially, a new field was now open for reaching a large number of persons requiring vaccination and revaccination, in order to put a stop to the ravages of small-pox, and he hoped that some of the gentlemen present would be able to assist the Committee in devising means for such a purpose.

Dr. Wm. M. Charters, of Georgia, described the terrible ravages of small-pox among the negroes at Savannah on the arrival of General Sherman's army,

and attributed it, not to any want of a correct appreciation of the utility of vaccination, but to the *imperfect manner* in which vaccination was performed.

It was the practice, to a great extent, to commit this subject to unprofessional persons. In the Southern States, especially, masters and overseers thought themselves equally competent with physicians for so simple an operation. But the result justified the conclusion that the disease they communicated was frequently a *vaccinoid* sore only, and not a vaccine vesicle. The operation was performed more with reference to making a *sore* than anything else, and that was regarded as the prophylactic, but exposure proved to the contrary. In other cases, however, and these were by no means insignificant, vaccination had been well performed and it had taken perfectly, but the susceptibility to it and to small-pox not having been exhausted, the individual was still liable. He therefore advocated exhaustive vaccination to begin with; let the operation be repeated until it ceases to produce an impression, and he believed susceptibility to small-pox would be destroyed for the whole lifetime of the individual. To accomplish this, he believed in the necessity of compulsory laws, requiring every person to be thoroughly vaccinated, under such penalties as would insure compliance.

Drs. Lee and Hibberd referred to the ineffectual State laws on the subject, and also to the no less ineffectual laws of England, and thought that something more was required.

Dr. Nebinger did not believe that such laws could ever be made effectual in this country, and thought that the work of the Committee to diffuse information—which, so far as vaccination without danger, or a belief in its prophylactic powers was concerned, was effectual—only now need be pressed to the equal necessity of *re*vaccination. On the necessity of *re*vaccination, he knew that there were yet many physicians and a multitude of other people needing information. He cited several cases in illustration. He hoped that the Committee would be continued, and that every member of the Section would do his utmost to press upon the attention of the profession and the public the facts that had been already presented in the last year's report.

Dr. Toner expected much good to result from registration, a subject that was now attracting much attention; and when it was so far advanced that correct information could be gained as to who was and who was not vaccinated, he thought that one great obstacle would be removed—the necessity of universal vaccination would be so much more apparent that the purpose of the Committee would be much facilitated.

On motion, it was voted that the Section recommend that the Committee be continued.

Dr. C. A. Lee introduced *leakage of gas pipes* as a subject well worthy of the consideration of the Section and of the Association.

On motion, it was voted that Dr. J. C. Draper, of New York, be requested to prepare a report for the next session of the Association on the leakage of gas pipes.

THIRD SESSION, MAY 3.

ON ALCOHOL AND ITS RELATIONS TO MAN.

This paper, on Alcohol and its Relations to Man, by Dr. Gerard F. Morgan, of Maryland, was presented and in part read by Dr. Dunbar, member of the special Committee with Dr. Morgan to present a report upon this subject.

After some discussion, it was, on motion, voted, that the report presented by the Committee on the subject be referred to a new committee, to report at the next session.

Dr. Dunbar of Maryland, Dr. T. Antisell, D. C., and Dr. N. S. Davis, Ill., were nominated, and the request referred to the Association.

Adjourned *sine die*.

SECTION ON SURGERY.

Dr. A. C. Post in the Chair; Dr. J. H. Burge, Secretary.

FIRST SESSION, MAY 1.

At a meeting of the Surgical Section of the American Medical Association, held at the Dental College, corner of Hanover and Lombard streets, Baltimore, Md., May 1, 1866, at 3 o'clock P.M., Dr. Alfred C. Post, of New York, was elected Chairman, and Dr. J. H. Hobart Burge, Secretary.

There being no report of the papers which had been referred to this Section, a motion was made to adjourn, to meet again in the same place at 3 o'clock P.M. on Wednesday, 2d instant. Carried.

SECOND SESSION, MAY 2.

The Surgical Section met at 3 o'clock, pursuant to adjournment.

Dr. Post in the Chair.

Dr. J. S. Cohen, of Philadelphia, offered a paper by Dr. J. M. Boisnot, of the same city, on Fracture of the Patella, and exhibited an apparatus for its treatment. On motion, the paper was referred to the Publication Committee.

Dr. J. S. Cohen read a paper on Vocal Paralysis, with Aphonia, cured by the application of stimuli and by the use of what he called vocal gymnastics. The paper was referred to the Publication Committee.

Dr. J. J. Woodward, U. S. A., chairman of Committee on Causes and Pathology of Pyæmia, presented a very elaborate paper. The Section listened for nearly an hour, when several members expressed their great interest in the communication, but owing to the shortness of the session it was voted to refer it at once to the Publication Committee, with the recommendation that it be published in full.

Dr. Woodward also presented some very beautiful photographs, illustrative of the success attained in microphotography. In these specimens microscopes of very differing powers had been used.

Dr. A. C. Post, of New York, exhibited an original instrument for the bilateral operation of lithotomy.

Dr. J. C. Hutchison, of Brooklyn, said he had used the instrument with satisfaction, and therefore moved that Dr. Post be requested to furnish a description for publication in the Transactions of this Association. Seconded and carried.

Dr. Post presented, also, a new instrument for making applications to the os uteri. It consists of a straight and rather slender pair of forceps, made short for convenience of carrying, but when in use elongated by a handle screwed thereupon. By a slide upon the forceps the blades are approximated and made to close firmly upon any object. The Doctor observed that it might be used either as a forceps to hold any substance which the operator might wish to apply, or to remove extraneous substances from the vagina.

Dr. Post also presented a small instrument to facilitate the introduction of insect pins for sutures; some of these pins being so delicate that without such guide they bend and become useless. The instrument consists of a sharp-pointed, slightly-curved, grooved needle—the groove being in its long axis. In using, the needle is to be introduced to the very position which

the pin is intended to occupy. The pin is then guided by the groove, carried to its place, and held there while the needle is withdrawn in the backward direction.

Dr. H. R. Storer, of Mass., presented an instrument which he called "The Clamp Shield," designed by him to lessen the dangers of extirpation of the uterus by abdominal section, and read a paper on the subject, which was referred to the Committee on Publication.

FOUR OPERATIONS FOR LITHOTOMY ON SAME PATIENT.

Dr. J. C. Hughes, of Iowa, reported a case of vesical calculi, in which he had four times performed the bilateral section in the same patient. When the second operation became necessary, lithotrity was attempted, but failed. At the time of the third operation the patient was much emaciated and very feeble, yet he recovered nicely. In less than another year the fourth operation was demanded, when twelve calculi were removed; drawings of these accompanying the papers. Dr. Hughes spoke highly of the bilateral as compared with the lateral operation, having performed it twenty-one times with the loss of but a single patient.

The paper was referred to Publication Committee.

Dr. Hughes also spoke of a new method of operating upon limbs which were both curved and shortened. He said Barton's mode was to saw out the V-shaped portion of the bone on its convexity; but as Dr. Hughes wished both to straighten and lengthen the limb, he cut down on the convex side, and passing a chain-saw around the bone, made a partial section on the side of its concavity, and then used such manual force as was necessary to straighten it—thus leaving a chasm to be filled instead of losing an additional inch.

It was moved by Dr. H. R. Storer, of Mass., that Dr. Hughes be requested to write a description of the operation for insertion in the Transactions of this Association.

On motion, the section adjourned to meet at three o'clock P.M. to-morrow, May 3d, in the same place.

THIRD SESSION—MAY 3.

The Section met at the appointed hour. Dr. Post in the chair.

Dr. Lewis A. Sayre, of New York, moved that Dr. Post be requested to furnish for the Transactions of the Association a description of his grooved needle, previously exhibited. Dr. Sayre thought the thanks of the profession were due to Dr. Post for this unpretending but eminently useful instrument. Carried.

Dr. Sayre then read a paper on Luxation of the Femur into the Ischiatic Notch, of Nine Months' Standing, reduced by manipulation.

Referred to Publ cation Committee.

Dr. Dewit C. Enos, of Brooklyn, read a paper on the Intra-oral Method of operating for Removal of Lower Jaw.

Referred to Publication Committee.

Dr. George M. McGill, U.S.A., presented a paper advocating the adoption of a periosteum flap in all amputations in the continuity—including a report of five cases. The Dr. exhibited casts of two of the stumps after these operations, which were beautifully oval.

Paper referred to Publication Committee.

Dr. Enos thought the suggestion of Dr. McGill a good one, but in one case in which he had made a periosteal flap in his own practice there had been such a reproduction of bone as to necessitate a second operation.

Dr. Louis Elsberg, of New York, read a paper On the Means of Diagnosis at present available in Diseases of the Larynz, with full directions for the use of the Laryngoscope.

On motion, referred to Publication Committee.

Dr. B. J. Raphael, of New York, stated that Dr. Montrose A. Polk, of ——, made a partial report in 1860, on ———, and moved that the committee be continued. Carried. On Motion of Dr. Raphael, Dr. E. Krackowizer, of New York, and Dr. J. S. Cohen, of Philadelphia, were appointed a Committee to report on the subject of Local Anæsthesia. Dr. Post made some remarks on the subject of partial anæsthesia and the coöperation of the intelligent patient with the practitioner.

On motion of Dr. B. J. Raphael, Dr. Henry D. Noyes, of New York, was appointed a committee to report on the influence upon vision of the abnormal conditions of the muscular apparatus of the eye.

On motion of Dr. E. Krackowizer, of New York, Dr. Raphael was appointed a committee to report on the comparative merits of the different operations for the extraction of vesicular calculi.

Whereupon the Section adjourned *sine die*.

Medical News.

PROGRESS OF THE CHOLERA.

Grand Duchy of Luxembourg.—According to the Wietz, Grand Duchy of Luxembourg (April 5th), correspondence of the *London Times*, the greatest alarm prevails throughout the district, owing to the dreadful ravages made by cholera at Diekirch and the surrounding villages. Between the evening of the 1st and the morning of the 3d, the deaths amounted to one hundred out of a population of only two thousand souls. All the means hitherto employed to arrest the progress of the epidemic have been in vain. To purify the air, large fires have been made in the streets, and the houses inundated with chloride of lime, but without effect. All who can are leaving the place. The disease made its first appearance at Clemenci, near Arion, to which village, according to report, it was brought by a workman from Paris. It soon spread to Mamer, Eich, Dommeldange, Weimerskirch, Luxembourg, and Diekirch, apparently following the water-courses.

On the same subject, the *Courrier du Grand Duché de Luxembourg* has the following:—The cholera has been raging at Diekirch for some days past with unusual violence. After carrying off numerous victims among the working class, it is now choosing its prey among the wealthier inhabitants.

Portland, Me.—A Portland, Me., letter of the 24th ult., states that "there have been no more cases of cholera than the two reported by the press. One of these was that of an escaped passenger from the Quarantine at McNab's Island, N. S., and the other is a matter of controversy."

Haverstraw, N. Y.—Dr. J. H. Sullivan, Physician to the Board of Health, Haverstraw, N. Y., in a letter to the *N. Y. Herald* of the 24th ult., contradicts the statement that cholera had recently manifested itself fatally in that village.

Washington, D. C.—Dr. Marsden, of Quebec, says that the cases at Washington are not Asiatic or epidemic cholera, and will not spread.

New York City.—The first pronounced but probably the second case in reality of cholera, occurred in this city on the 30th ultimo. We are led to be thus qualified in our statement, since the fatal case in Delancey street, reported some weeks ago by the physician in

attendance, although still in controversy, had symptoms equally well marked. But be this as it may, the case to which we have alluded in the first paragraph, occurred in the person of an industrious Irishwoman, aged thirty-five years, who occupied, in common with two other families, a frame house, not noted for the salubrity of its immediate surroundings, upon the east side of the Third Avenue, between 92d and 93d streets. The building is situated upon a high bluff, swept by breezes from off Ward's Island, in which certain, or according to some observers, merely alleged choleraic cases occurred during the period extending from the latter part of last November to the close of the succeeding month. According to the report of the *Daily Times*, this woman, "just before she became ill, had with her own hands cleaned out the privy belonging to the house, and had used the contents as manure in planting potatoes in the garden." At noon, although feeling somewhat indisposed, she partook of a frugal dinner, complained of pains about 3 P.M., was in a state of collapse at 4 P.M., and died on the 1st inst., at 11 A.M. An autopsy revealed a general healthy condition of all the organs except the stomach and intestines, in which "the rice-water secretions" were abundant.

Joshua Jenkins, aged seven months, a son of the above, died at the Battery barracks, on the 4th instant, of the same disease.

Another case made its appearance, on the 2d instant, at 115 Mulberry street, in a five-story, double tenement house, through the centre of which runs a hall four feet wide. The rooms measure fifteen feet by eleven, and the bedrooms attached, each about eleven by seven, with one small window apiece. These windows, on the side of the house adjoining, No. 113, open into a recess seven feet by two feet, which exists between the two houses. "This recess," to quote the language in full of Dr. Southack, from whose report we have condensed the above description of the premises, "is in a most filthy condition. Slops and offal from both 113 and 115 are freely thrown there, and the inhabitants bitterly complain of the odor arising therefrom. The lower windows on the side adjoining 117 Mulberry also open into a recess between the two houses. This is also in a vile condition; so much so that the inhabitants in some of the rooms have nailed up the windows permanently to escape the stench."

Add to this the custom borrowed from untutored animals confessedly low in the scale, of depositing fæces in the halls, and the picture of this haunt of the lowly may be pronounced complete.

Thus the patient, Kate Dooley, aged 35 years, who had been whitewashing on the 1st throughout the entire day, after a repast upon some bread and meat at 3 P.M., was surrounded by the very influences to invite the vomiting and purging which seized her the next day at 2 o'clock A.M. She, however, rapidly recovered.

Efficient sanitary measures have been adopted to arrest the spread of the disease, which, in these instances at least, is not traceable to any violations of quarantine laws.

Overloading Passenger Ships.—Mr. Washburne, U. S. Representative from Illinois, has given notice to the House that the Committee on Commerce have prepared a very important bill in regard to overloading passenger ships, considered in its relations to the question of cholera.

Changes and Appointments in the Metropolitan Health Board.—Dr. Stephen Smith has been appointed Hospital Superintendent of the district. Dr. Chas. McMillan, late Surgeon U.S.V., has declined the position of Chief of the Barracks Hospital, recently tendered him. Dr. Chas. W. Packard, promoted from a clerkship to an inspectorship, vice Dr. Alba Blaisdell, resigned. Dr. Thomas F. White, elected clerk, vice Dr. Packard, promoted. Two Homœopathic practitioners have also been elected clerks, agreeably to the petition of the New York County Homœopathic Medical Society. They are to have the exclusive medical attendance upon one-fourth of the patients expected to occupy the Barracks Hospital, and one-half of those admitted into the Five Points Hospital.

New Hospital at Hoboken, N. J.—A new four story and commodiously arranged hospital has been opened at Hoboken, N. J., under the auspices of the "Sisters of the Poor," at a cost of thirty thousand dollars. It will contain one hundred beds, and be supported by charitable donations. All the physicians in Hoboken have volunteered their professional services.

Wisconsin State Hospital for the Insane.—The Trustees of the Wisconsin State Hospital for the Insane have invited proposals for enlarging the State Insane Asylum, the work to be completed by the 1st of July, 1867. This is the asylum for building which, on so large a plan, Governor Barstow was so severely censured by his political enemies.

Sanitary Matters at Halifax, N. S.—The municipal authorities of Halifax, N. S., have designated Lawler's Island a Quarantine Station, and have ordered the burning of the infected bedding, clothing, and other débris thrown overboard from the England, and found floating in the waters of the harbor.

Magnesium.—Magnesium is made in Boston from dolomite or magnesian limestone, by the Sonstadt method. The actinic power of this metal is 1-36th that of the sun, and the intensity of the light is 1-525th that of the same luminary. In consequence of its expensiveness, various substitutes have been proposed by photographers, among which the following mixture seems to have found favor: 24 parts of well dried and pulverized nitrate of potash, 7 of sulphur, and 6 of red sulphide of arsenic. It is claimed that this combination has as great actinic power as magnesium, though not so suitable for indoor use on account of the odor.

Sulphate of Quinine in Photography.—The window of a photographer's "dark room" may be painted with a mixture of an acid solution of sulphate of quinine in dextrine or gum arabic. The mixture should be applied on a sheet of paper, and this placed on the glass, and it is said no actinic rays, even on the brightest day, can pass a window so prepared.

Speculations Regarding the Sun and Earth.—Prof. Thomsen, of Copenhagen, assigns to the sun's heat, supposing it to be maintained by the fall of aërolites, a limit of 300,000 years, and to the period of the cooling of the earth from universal fusion to its actual state, 98,000,000 years. These calculations are the lowest given by any mathematician.

Dr. Herman Guleke, Assistant Physician to the Emigrant Hospital, Ward's Island, resigned his position on the 2d inst.

Dr. Philo G. Rockwell, of Waterbury, late Surgeon of the Fourteenth Connecticut, has been appointed Surgeon-General on the staff of General Hawley, the recently elected Governor of Connecticut.

Vital Statistics of Great Britain.—The Registrar-General of England states that for one week the births registered in London and twelve other large towns of the United Kingdom, were 4,419; the deaths 3,506. The annual rate of mortality was 30 per 1,000 persons living. In London, the births of 1,175 boys and 1,099 girls—in all 2,274 children—were registered in the week. In the corresponding weeks of ten years, 1856–65, the average number, corrected for increase of population, was 2,072. The deaths registered in London during the week were 1,574.

The Hydrate of Lime.—Liebig suggests that, in close rooms and on shipboard, deficient ventilation may be compensated by the use of hydrate of lime. Eighteen or twenty pounds of slaked lime will absorb thirty-eight or thirty-nine cubic feet of carbonic acid gas, which would be immediately replaced by an equal volume of fresh air entering through the crevices.

The Cretinism Theory.—M. Saussure's theory that cretinism did not exist in places 1,000 metres (or 3,280 English feet) above the level of the sea, was disproved by the Sardinian Commission, who found numerous cases in localities elevated 1,600 metres (or 5,248 feet) above the sea. In one village of this elevation, ninety cases of goitre and cretinism were found in every 1,000 of the population.

The Iridoscope.—At the last sitting of the Academy of Sciences at the Institute of France, Dr. Jules Cloquet presented a very interesting optical instrument called a "Iridoscope" by its inventor, M. R. Houdin, and by means of which the spectator may see deeply into the interior of his own eyes, and follow the movements which take place during the process of vision. The Academy referred the instrument and the paper which accompanied it to MM. Becquerel and Foucault for examination.

The New Metal "Indium."—Fresh sources have been discovered of the new metal indium. Prof. Schrotter communicates to the Vienna Academy that Dr. Kachler, a pupil of his, has found it in the zinc blende of Schonfeld, near Schlaggenwald, where this mineral occurs associated with tin ore and other minerals in a bed of steatite, in such quantity that a few grammes of this mineral yield an appreciable amount of this substance. The blende is roasted, and then dissolved in sulphuric acid; on treating this solution with metallic zinc, the indium and some traces of other metals are precipitated, from which it is afterwards separated.

St. Vincent's Hospital, Dublin.—The Managers of St. Vincent's Hospital, Dublin, Ireland, have purchased the splendid residence known as Lyndon Castle, Blackrock, for the purpose of converting it into a sanatorium, to which they will send the convalescent patients to enjoy the benefit of country air, sea-bathing, etc., previous to returning to their homes. This is the first sanatorium ever established in Ireland.

Aluminate of Soda in Soap-Making.—A Philadelphia company are now using, instead of caustic soda, aluminate of soda for soap-making.

Dr. John H. Slayter, who volunteered his services in connexion with Drs. Garvie and Gossip, in the capacity of Health Officer upon the occasion of the arrival of the cholera ship England, at Halifax, N. S., died of cholera, April 17th, after an illness of twenty-four hours. His remains were interred at the Quarantine Station, McNab's Island, on the succeeding day. The House of Assembly have unanimously voted $2,000 to his widow, accompanied with encomiums on the courage and devotion of the deceased in risking his life for the preservation of others. The monument proposed to be erected to his memory by the people of Nova Scotia, will occupy a conspicuous point on McNab's Island.

Dr. Benjamin Vreeland, Surgeon U.S.N., with rank of Lieutenant-Commander, according to recent advices, died on the Coast of Africa, on board the sloop-of-war Kearsarge. Date of death not given. Since the above was in type, we have learned additional particulars from a letter to the New York *Herald*, dated Madrid, April 24. According to this authority, "the first victim of the dread disease (yellow fever) was the amiable, skilful, and accomplished surgeon, Dr. Vreeland, who expired after an illness of five days, during which time he was unable to prescribe for a single fellow-sufferer."

Another letter from the commander of the sloop is in this likewise quoted to the effect that "the fever made its appearance on board on the 15th of March, immediately after leaving Sierra Leone."

Cholera and a bad Odor from the Mouth.—Under this heading a writer in *The Dentist* (or *Zahnartzt*), Leipsig, 1866, speaks of the dangers in the present cholera season from bad odors arising from the mouth, in consequence of caries of the teeth. He says: "It has already been noticed how much the dentist is exposed to evil influences from this cause, since he is constantly in the treatment of caries, removing fungous growths and infusoria, which, being the cause of all putrefaction, may bring disease into his dwelling." He then recommends to patient and physician as a mouth disinfectant, lozenges composed of twenty-four grains each of hypermanganate of potassa and hyperoxydate of baryum, rubbed up with sugar and glycerine—dividing the mass into 144 lozenges. The mass should be well triturated and become soft and homogeneous, similar to the lozenges of confectioners. The trial of this remedy for a bad odor from the mouth is said to be "extraordinarily satisfactory." Every ill-smelling mouth will become by their use entirely odorless.

Dr. William Goodell (late of Constantinople—for many years medical attaché of the U. S. Legation in Turkey), having returned to this country, has recently been appointed Resident Physician to the Preston Retreat—a lying-in hospital established in the city of Philadelphia for indigent married women of good character, by the liberality of the late Jonas Preston, M.D.

Health of Dr. B. Ogden.—We are happy to announce a progressive improvement in the health of Dr. Benjamin Ogden, who was prostrated by paralysis in November last. We trust that he may soon be able to resume his labors in the special vocation to which he has devoted so many years of his life. His many friends will rejoice in his restoration.

Guadalupe.—The last dates from Guadalupe state that the cholera is disappearing. The official statistics published by the government show a mortality from this disease of 10,806 out of a population of 149,107.

Original Communications.

REPORT OF A CASE OF APHASIA FROM APOPLECTIC CEREBRITIS.

By HARVEY E. BROWN, M.D.,

ASSISTANT SURGEON, U.S.A.

In the first number of the "Medical Record" is an article by Prof. A. Flint, Sr., on the subject of aphasia in connexion with hemiplegia, together with a report of cases. In this article the distinguished author expresses the hope that others may "contribute to the accumulation of facts for the elucidation of the affection." The case which follows, occurring in the hospital under my charge during the past winter, may perhaps be adding something to the history of this curious affection, and is presented with that view; and although differing in some material points from the cases presented by Dr. Flint, is yet, I think, of the same general character.

Private Joseph Bois, Co. "C," 3d Battalion, 17th U. S. Infantry, a Canadian by birth, aged thirty, unmarried, apparently a hard drinker, was admitted to the Post Hospital, at Hart Island, N. Y., about 6 P.M., February 2, 1866. At this time the following symptoms, principally, it is true, of a negative character, presented themselves:

The patient was in a state of profound insensibility, from which it was found impossible to arouse him. The pulse was natural as to frequency, but full and tense. The pupils were fixed, but neither contracted nor dilated; there was no strabismus. Respiration was rather slow, but otherwise naturally performed. There was no stertor. The under-clothing he had on was wet, and gave out an odor of recently passed urine. A careful examination of the head failed to discover any wound or injury of the scalp. Nothing could be learned of the previous history of the case, except that the man had been found lying insensible in his company quarters, and was at first supposed to be drunk. There was no odor of liquor about the breath.

February 3d, 9 A.M.—Condition of patient very much the same as yesterday, except that he continually draws his knees up towards the abdomen as if in pain. No abnormal symptom could be discovered on examination of the abdomen. He has no paralysis.

About 3 P.M. to-day he rose from his bed and walked to the water-closet at the end of the ward. When stopped by the nurse, he evinced no perception of what he was doing, but stared stupidly at him and passed on. Having had an evacuation from his bowels, he returned without trouble to his proper bed. In the course of the afternoon he repeated this action twice. Otherwise he shows no signs of returning consciousness. The pulse and respiration remain as before; the eyes are fixed and staring; the countenance otherwise being natural. The skin was moist; the condition of the tongue was not noted, it being found impossible to get him to protrude that organ.

February 4th.—A decided change has taken place since last night. The pulse this morning is 100, and weak and feeble; the respiration preternaturally slow. The patient remains insensible, but to a less extent than before. When spoken to sharply he opens his eyes, but without evincing any recognition of objects or persons about him. The bowels and urine are natural and regular. It is noticed that a blister, which was applied to the back of the neck, was unusually long in producing its effect.

February 7th.—There has been no material change since last report in either the condition of the patient or the symptoms. The pulse continues feeble and quick; respiration slow; bowels regular. Patient has gone as before to the water-closet. This morning, for the first time, he makes a reply to questions asked him. He answers invariably "Oui," or "Yes," without any regard, however, to the nature of the question.

February 8th.—This morning the pulse is 115; small and weak. The respirations are slow and labored. The extremities are cold; the insensibility more profound. The countenance has a haggard look; the eyes are closed, and on the lids being raised have a fixed and glassy appearance. Everything about his condition indicates approaching dissolution. Sinapisms were applied to the feet and epigastrium, and carbonate of ammonia gr. v. given every hour, with beef-tea *ad libitum*. In the evening there was a decided improvement in his condition.

February 9th.—Improvement continued; pulse normal in frequency and stronger; respiration, bowels, etc., natural. He again replies as before to questions. His appetite seems to be very good, for although he expresses no desire for food, he eats freely what is fed to him by the nurse.

February 12th.—Well marked ptosis of the left eyelid appeared this morning. There is no paralysis of the seventh pair. The patient to-day for the first time protruded his tongue. It is natural in appearance, and has no inclination to either side. Apart from the ptosis, there has been for the past three days a decided improvement.

February 17th.—A gradual improvement has taken place since last report. The pulse is now natural; the bowels regular; appetite good, etc. The ptosis is still persistent, and on his protruding the tongue this morning, a slight deflection was noticed to the left side. He has improved in his speech to the extent of adding the word "Sir" to his vocabulary. He now says "Yes, sir," or "Oui, sir." to everything said to him. He also rises from bed and stands at attention when the surgeons visit the ward.

March 3d.—Improvement gradual. The patient has gained in flesh and strength, and has now the appearance of a well man. The ptosis has partially disappeared, but the deflection of the tongue to the left side still continues. He has improved considerably in speech, and makes efforts to express himself in French, but his speech is thick and faltering, and he talks with great difficulty. He will commence a sentence, speak a few words, then stop and point to his head as if to imply that the difficulty was there and not in his tongue. The trouble now appears to be a want of association of ideas. He knows what he wants to say, but cannot associate the proper words to give expression to his idea. This is further shown by his using words of both French and English in the same sentence.

On the 3d of April he was discharged from hospital, by reason of his regiment being ordered away from the post. At the time of his discharge he was to external appearance as well as ever. The ptosis had nearly disappeared; the inclination of the tongue to the left entirely. The aphasia, however, remained the same as stated in the last note.

A day or two after he joined his company for duty I noticed him on evening parade, and observed that during the exercise of the manual of arms he was a moment behind the rest of his company in executing the various commands, as if it took him time to arrive at an accurate conception of the orders given.

The treatment adopted in this case consisted of cups and blisters to the back of the neck and temples, and subsequently, by the advice of a distinguished Army Surgeon, of the application of a moxa of camphor along

the course of the spine. This was several times repeated, and under its use he improved rapidly. In addition to this his strength was supported during his state of coma, when he was unable to swallow, by enemata of beef-tea and other nourishing articles. Subsequently he was placed on a tonic mixture, of which the sulphate of cinchona was the basis, which he continued to take until discharged from hospital.

The diagnosis was apoplectic cerebritis, followed by but slight softening of the brain. There was a remarkable disproportion between the amount of paralysis present and the persistence of the aphasia; the former being confined to the left eyelid, and a very slight deflection of the tongue. The fact of his walking as he did to the water-closet, when otherwise in a state of profound coma, is an anomaly which I cannot explain; perhaps others with more experience may do so. When he first did so I was inclined to think he was malingering, but the subsequent history of the case convinced me that in this I did him injustice. The case is further of interest in that the paralysis existed on the left side.

A CASE OF POISONING BY MORPHIA.

ARTIFICIAL RESPIRATION—HYPODERMIC INJECTION OF BELLADONNA—RECOVERY.

By THEODORE R. VARICK, M.D.,

OF JERSEY CITY, N. J.

I WAS called on the 18th of April, 1866, between one and two o'clock P.M., to see S. K., who had taken, two hours previously, two ounces of the following mixture: ℞ Tr. digitalis, ʒ iij.; Tr. lupulin, Tr. valerian, āā ʒ iss.; Spts. vini Gallici, ʒ j.; Sulph. morphiæ, gr. iv. M.

I found him in profound coma; pupils contracted; inspirations eight per minute; pulse eighty and full; countenance livid; stertor; surface warm and bathed in perspiration.

The cold douche to the head was resorted to, and persevered in for thirty minutes, without effect.

Respiration becoming less frequent, and the stertor increasing, he was taken from the bed and laid on the floor, when artificial respiration by Hall's method was commenced. This was continued until four o'clock, when it was suspended for a minute and a quarter, during which time it was evident that there was a total suspension of all reflex action, there being no effort at inspiration, and the only evidence of vitality was the continuance of the circulation, which retained its force and rhythm to a remarkable degree.

The lividity, which had nearly disappeared, was rapidly returning. Artificial respiration was again resorted to, and continued until five o'clock, when it was again suspended for a period of a minute and a half.

During this time, as in the first instance of suspension, the same absence of the "besoin de respirer" existed as before, while the pulse alone encouraged a perseverance in the efforts at restoration. Lividity increasing.

Dulness on percussion as high as the fifth rib on the right side; while above that point, and on the left side, the thorax was resonant and the respiratory murmur distinct during the artificial process. Accumulation of frothy mucus about the fauces, producing a gurgling, sucking sound, with paralysis of the muscles of the larynx and tongue, reudering asphyxia imminent.

The tongue was seized with a forceps, drawn forward, and secured by passing a needle armed with a double ligature through its substance, which was held by an assistant. The artificial process was again resorted to with feeble response.

At this period the vital forces seemed rapidly failing, and I determined to try the effect of belladonna hypodermically administered. I procured the following: ℞ Ext. belladonnæ, gr. x.; aq. destillatæ, ʒ j. M. Of which I injected four minims under the skin of the left arm, near the insertion of the deltoid.

No perceptible effects following, artificial respiration being in the meantime kept up, after the expiration of thirty minutes, I again injected four minims near the same place, with no better result. 8 o'clock P.M.—Pulse seventy, with some intermission. Pupils contracted. Profound coma. Responds seldom and feebly to the artificial efforts at respiration.

Belladonna, four minims, injected as before, with a slight improvement in reflex action.

Hall's method was continued from this time until about ten o'clock, with no further improvement, when belladonna was again injected in the same quantity as before, in the right arm, just below the deltoid. The effects were very marked, respiration being carried on with slight and occasional assistance. Stertor subsided, and almost a total disappearance of lividity. No effect on the pupils.

At the expiration of thirty minutes belladonna was injected in the same quantity as before, and near the location of the last, with almost magical effect, the pupils rapidly dilating, with a return to consciousness in less than fifteen minutes.

The subsequent treatment consisted in the administration of strong coffee and the keeping up of constant excitation for two hours longer, when, as there remained but slight drowsiness, he was permitted to rest for the balance of the night.

Apart from the fact that artificial respiration was kept up for over eight hours, one of the most noticeable features of the case was the force and regularity of the circulation, which was probably due to the cardiotonic properties of the digitalis contained in the mixture. The antidotal properties of belladonna were manifested to a remarkable degree, by the return of consciousness as soon as its physiological effects were produced. The results obtained in this case commend the treatment to the profession as a speedy and reliable resort in similar emergencies.

APPROPRIATIONS TO DIFFERENT MEDICAL INSTITUTIONS.—Under the act to enable the Board of Supervisors of the County of New York to raise money by tax for the use of the Corporation of the City of New York, and in relation to the expenditure thereof, the following, among other appropriations, have been made:—Board of Health, $2,500. City Dispensaries, $8,000. For the construction of an Inebriate Asylum in the city of New York, established by chapter 141 of laws of 1864 (to be paid by the Comptroller, from time to time, on the requisition of the Commissioners of Charities and Correction), $100,000. For "Ophthalmic Hospital," under resolution of Common Council, approved December 30, 1865, $2,000. For "St. Luke's Hospital," under resolution of Common Council, approved December 30, 1865, $4,000. For "Magdalen Female Benevolent Society," to be disbursed under direction of the Commissioners of Correction and Charity, $3,000. For Ophthalmic Hospital, to aid in erection of Building, $3,000. For "Hospital of the Sisters of St. Francis," $5,000. Nursery and Child's Hospital, $5,000.

PUBLIC BATHS.—A resolution to establish public bathing facilities for the people of this city, passed the Board of Councilmen on the 23d ult.

Original Lectures.

ON CHOLERA.

By A. CLARK, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

Lecture V.

The Natural History of Cholera as bearing on the question of the Contagiousness of the Disease.

You perhaps feel, gentlemen, that I said enough on the question of the contagiousness of Cholera at our last meeting; but I wish you to be informed regarding many other facts that belong to its natural history, some of which appropriately fall into the line of the argument.

I have already stated that personal communication and contact with the sick does not seem to increase the liability to the disease. The eight physicians of Astracan, where this disease first appeared in Europe, who wrote to the authorities of Moscow, before it had reached any other part of Russia, said: "We have handled our patients, we have rubbed the sick, we have visited the hospitals with due care, the wards being crowded with patients, and we have not feared to respire the breath of these sick persons." They state that the breath had an odor of something burning. They took no precautions either for themselves or their families, and none of them suffered from the disease. This was, at the time it was made, a very important statement. Then they go on to say that nurses and persons who had emptied the utensils were as free as themselves from the disease. It is further stated that the patients in the hospitals were frequently clothed in the garments of persons who had died of Cholera, and yet were in no manner affected more than others. Dr. Houston, in a paper recently published in the *Richmond Medical Journal*, states that a newspaper editor of Wheeling, as a sort of bravado, put on the clothes of a person who had died of cholera, and lay through the night with these garments upon him, and did not suffer by the disease, though "distilled to jelly by the act of fear." The European physicians frequently refer to the fact that the wife, or child, or husband, has slept with the sick person, and not taken the disease. Infants are spoken of in hospital reports as drawing their nourishment from their sick mothers' breasts almost to the moment of death; and yet these children have not taken the disease. These facts, added to what was stated to you the other day, seem to make a pretty strong case against contagious emanations from the bodies of the sick. Dr. Houston states (and this is a statement I repeat in the name of humanity) that at Wheeling, where the disease prevailed with great severity in 1833, the proportion among those interested in the sick, who sought them out and nursed them, and who had the cholera, was much less than among those who carefully avoided the sick-room. The brave and humane resist epidemic influences under which the timid and irresolute sink.

There are certain other considerations that bear upon this question. Small-pox, measles, scarlet fever, are always to be found in this city, and in every large city; they do not become extinct at any time. Cholera has a different history. It comes in a great wave of invasion; it lasts a variable period, from four to fifteen months, and then disappears, after an interval, to come again by progressive steps in the same manner as at first. If the disease is really contagious, the question arises where, in large communities and crowded places, would the communicability cease, or why should it suspend its ravages any more than small-pox or scarlet fever? It has nowhere, so to speak, become naturalized. It remains in its native land, to break out and spread from time to time; but it has reached Europe only as a foreigner, and this country in the same character.

Again, the invasion is too rapid. When it strikes a particular community, large numbers fall sick in a period of time much too short to countenance the supposition that the poison is generated in a particular person, and from him communicated to others, and so spreading from person to person. This implies time for incubation and development. When cholera appeared in Paris for the first time, it was in the latter part of March, and during the month of April it had accomplished the greater part of its work. Eighteen thousand four hundred and sixty-three persons died of cholera that year in Paris, and nearly thirteen thousand had been made the victims of it before the end of April. In eighteen days from the time it commenced, seven thousand had fallen. When it appeared for the first time in New York it was declared epidemic on the third day of July; during that month of July seventeen hundred and ninety-seven persons had died of it, out of a told mortality during that epidemic of three thousand five hundred and thirteen. During the first month of the disease the mortality exceeded the half of all the mortality. Perhaps the matter can be studied better in smaller communities; and for the purpose of letting you see how it sometimes operates in villages, I refer to a history, given by Dr. Houston, of an epidemic in a small village named Bridgeport, on an island opposite Wheeling, in the Ohio river. The village contained at the time a population of between two and three hundred persons. It is screened by a border of trees on the side towards Wheeling, but the track of the great western travel from this city crosses the island. Cholera appeared in Wheeling on May 15, 1833. This little village remained untouched, though in free communication with Wheeling; the communication being limited only by the fears of the people, whose necessities, however, compelled them to go there frequently, until quite the end of June. Then a single cholera case occurred of an evening, and in thirty-six hours twenty-two persons had died in neighboring houses; and this number of deaths would probably stand for a considerably larger number of cases. In another hamlet, five miles below Wheeling, screened from the river by an undisturbed native forest, on alluvial ground, and backed by hills that protected it considerably from the winds, were a few houses inhabited by poor people, and during the prevalence of cholera in Wheeling and Bridgeport, no one was afflicted in this village. After it had entirely gone from Wheeling in a single night, nearly all the people of this hamlet were attacked, and in twenty-four hours one-fourth of them were dead. Now this does not look like contagion. Contagion cannot reproduce itself and spread in this way, if we can judge from what we know of it in other diseases, in this short time. There was some poison operating upon these people, and affecting them all in the same manner and nearly at the same time. A somewhat similar history is reported by Dr. Jackson, and recorded in the third volume of the *Transactions of the American Medical Association*. He says that during the prevalence of cholera in Philadelphia in 1849, at a healthly locality, twenty-six miles distant from Philadelphia, lived two farmers, father and son. None of their families had been to Philadelphia within a period of three weeks before the occurrence of cholera among them. In one of the families, that of the son, there were three boarders, carpet-weavers.

One of these weavers had been to Philadelphia within a week of this outbreak. On July 11th, these two families, living three-eighths of a mile apart, but in continual communication, were simultaneously seized with cholera. In the father's house, the father and one other person were attacked; and in the son's house a young man who was living with him. This was in the evening, and at midnight two other persons were attacked in the house of the son; and from that time on, in the course of eleven days, six more were attacked, making eleven out of fifteen persons, of whom five died. How shall we account for the attack of the father and one inmate of his family, and of one of the son's family, seized as it were almost at the same instant? The physician who makes the report states that the neighborhood was healthy till the 11th, and that on the 12th he was called to see some cases of cholera-morbus—he does not denominate it cholera—and in a period of two weeks there were a great many cases of dysentery, several of which proved fatal. You may say this weaver brought the poison from Philadelphia. That is possible, but he was not sick; the three weavers all escaped. Whether he brought any baggage or goods of any kind does not appear in the report. Pettenkofer advocates the opinion that the diarrhœal evacuations are as dangerous as the choleraic, and he would doubtless urge that either the weaver had a diarrhœa, or that a diarrhœa had continued three weeks in some other member of these families who had previously visited the city. It seems to me if the weaver brought anything poisonous from Philadelphia he must have brought something that could be let loose, and produce a similar state of air in the house of the father and the house of the son, and could soon infect the neighborhood.

Then refer to the occurrence already cited in the Massachusetts State Prison. Dr. Morris was called up to see one patient who had been in solitary confinement seven years, and before he could return to his bed he was called to four others in distant sections of the building; and within forty-eight hours two hundred and five persons were attacked. Such occurrences are not in conformity with any of the known laws of contagion.

There are facts of another class. The mode in which the disease subsides in many instances is worthy of notice. Many of you have heard of the cholera in the grand army of the Marquis of Hastings, in India (1817). Marching through a low country affected by the disease, he lost, in twelve days, seven hundred and sixty-four of his soldiers, and the report runs, thousands of camp followers. He crossed a clear bright stream, ascended its high, dry banks, encamped there, and the cholera ceased at once, having had a course of twelve days instead of twenty-eight or thirty, which has been regarded as the usual term of the disease in the armies of India. If it had been contagious it would seem that the poison must have been already introduced into the bodies of many, who would still become sick in the new situation; indeed, its duration should not have been materially influenced by change of place. Another account, somewhat analogous, is given of a regiment of English troops that arrived during the prevalence of cholera on the Ganges. They were reported to have been in the very best condition of health. They were to be sent into the interior, and were to go up the Ganges in boats. They started in two divisions, one a month after the other. Immediately after the first division came into the portion of the river along which the cholera was prevailing, they began to suffer; the disease proved more severe as they passed into those regions most intensely affected, and grew less severe as they passed into districts where it was less violent; and when at length they emerged from the affected region, the disease ceased altogether among them. One month after the second division undertook the journey in the same way, was affected in exactly the same manner, and relieved under exactly the same circumstances. It is true that armies marching in India have often carried the cholera with them into healthy districts, and it has prevailed among them as an epidemic in such regions, the usual duration of which is given as thirty days, and the term of its greatest severity eighteen days. In the instances now cited the disease was not governed by these precedents, but appears to have been wholly under the control of local influences.

Dr. Bryson, a surgeon in the English navy, reports that the fleet to which he was attached in the Mediterranean, coming from an entirely healthy region, touching at no port where cholera prevailed, and coming into the eastern region of the Mediterranean Sea, the men were attacked with cholera on the ships while yet some miles from the land, and before any communication had taken place. This statement is cited as an evidence that the winds can transport the efficient cause of the disease, whatever that may be. But admitting such transportability, the question still remains whether the thing transported is a contagious principle or a poisonous product from the air or earth. So far as we know, there is no possibility of carrying the poison of typhus, or smallpox, or measles, or scarlet fever, upon the wind for any such distance. Indeed, it is not probable that either of these diseases can be communicated beyond a few feet—certainly, under ordinary circumstances, not exceeding a hundred—while miasmata are much more widely diffusible. Facts have been observed in the harbor of this city which justify the belief that the yellow fever miasm can be carried on the wind over the unobstructed surface of the water a distance of one mile; and that the cause of intermittent fever can be transported by the same agency over an open country a still greater distance, is generally admitted.

There are some other facts that bear upon this question. It is reported by Drs. Ball and Gull that in Oxford, England, the disease just divided the town, and only one case occurred in the exempted portion; and the statement is, that that part which was affected with cholera was low and incapable of drainage, and that the people were of less virtuous habits, and less cleanly. It would hardly be probable that a disease that was contagious would not have passed this line, particularly since the persons who lived in the poorer part of the city would be continually employed by those who lived in the better part, for the intercourse was be uninterrupted. In India it appears that it is not very uncommon that one part of a town will be entirely or almost entirely exempt, and another part heavily afflicted. This fact was noticed again in the same report. There is, it appears, a portion of Manchester, England, where there are pigs and pig-styes, low undrained ground, uncleanliness, and every source of insalubrity, called "Little Ireland." When cholera visited Manchester it pervaded nearly the whole town except this "Little Ireland," and there the number of cases was but five. In the neighborhood, only three hundred yards distant, was a somewhat similar district, that suffered very heavily. Analogous facts could be cited in considerable numbers, all of which seem to point, not towards contagion, but rather to some special local agency existing in one district and not in another; for the five cases in Little Ireland were quite enough to have generated and diffused the contagious principle, if it exists, though the disease in each may have been contracted in another part of the city.

Then there is another important fact—that cholera in Europe, and with certain limitations in this country, has

its avant-courier. The diarrhœa and other disorders of the bowels, of which I have already spoken, precede the actual advent often for weeks, sometimes for months, affecting not alone those who are afterwards to be the subjects of the disease, but to speak a little widely, the whole population; affecting not alone the towns and places to be afterwards scourged, but large districts which are not otherwise visited. Now, is there anything analogous to this in the history of contagious diseases? Does it not seem that the elements are tainted by the breath of the far-off pestilence, as no human emanations can taint them; that the air or earth, or their constituents or accidents, have already assumed an unfriendly attitude towards man, and are in league with the coming scourge? This fact will appear more strikingly by contrasting the approach of cholera in Europe with its advent in this city. It has been my fortune to have witnessed all the epidemics that have occurred in this country. I remember that of 1832; and though a student of medicine in my first year at the time, I observed and feel authorized to say that previous to the invasion, on the 24th of June, there was no diarrhœa prevailing among the people. When the cholera became epidemic diarrhœa became general. I scarcely knew a person at that time who was not more or less affected by it, and it has been the same, if I can trust my recollection, in every recurrence of the disease; and yet as the disease spread through the country, after making a lodgment in New York, it was preceded, at least in most instances, by the same precursors as in European towns, while in many places diarrhœa prevailed, and cholera did not follow it.

The conditions of insalubrity that I just now referred to are very conspicuous in the history of cholera. Everybody knows that it chiefly selects those parts of towns that require the most and receive the least official cleansing. Is that the case with the recognised contagious diseases? It is true that wherever people are crowded together in great numbers, there typhus, and small-pox, and scarlet fever, and measles, will assail a larger number, and a larger proportion even, than in portions of a town where the people are more favorably situated; but overflowing or uncleansed privies, neglected cesspools, a leaking or obstructed soil pipe, a soil saturated with decomposing organic matters, imperfect drainage, well-water contaminated by infiltration from drains and excrementitial impurities, imperfect ventilation, personal uncleanliness, open sewers, and similar causes of ill-health or sickness, do not aid in multiplying the cases of these affections, although they doubtless augment their mortality by depressing the vital powers.

In the greater number of places where cholera has prevailed, it has been most mortal in the warm months of the year. There is an impression that the cholera does not prevail in the cold seasons. It is undoubtedly true that when it is on its march as an epidemic from one region to another, its progress is frequently checked by winter and renewed in the spring; and yet I read you an account of a severe epidemic occurring in that very large pauper school at Tooting, which began in the winter. In St. Petersburg, and particularly in Moscow, the disease has prevailed twice in winter, and has been severe. In Scotland it prevailed in the winter 1848–9. It was most severe in Glasgow and Paisley at that particular period, and it diminished in severity as the warm weather came. But that you may get a better idea of the exact facts in relation to this subject, I will read to you from the Registrar-General's reports the number of deaths that occurred in England in the successive months, from July, 1848, to December, 1849. In July, 1848, in all England there were 189 deaths; in August 232; in September 187; in October 325; in November 386; in December 400; in January 658. And now it begins to decline. In February there were 371; in March 302; in April 107; and now as warm weather comes you observe it begins to increase. Its minimum is in April; in May there were 327; in June 2,046; in July 7,570; in August 15,872; in September 20,379. You observe the greatest fatality in winter was 658, in the month of January. The greatest fatality in the warmer months is 20,379, in the month of September. From this point it again declines; in October 4,654; in November 844; in December 163. Then again you are to bear in mind what I just now stated regarding the occurrence of the disease in Paris in 1832. Its greatest mortality was in April, before the warm weather had fairly begun; and as the summer came on it had nearly disappeared.

But when you take the great history of the epidemics and sum up all the facts, there is no manner of question that it produces many times greater mortality in summer and the first month of autumn than in all the other months of the year.

Indeed the statistics we have just been considering give 43,821 deaths to the months of July, August, and September, 1849, leaving only 8,034 for all the other months.

Is anything like this true of the contagious diseases? I know very well there are severe epidemics of the three of the diseases I have taken as types of the contagious affections in summer; but when you look through a series of years and mark their occurrence in different places, as we have considered the relations of cholera, we do not find that they prevail more extensively or are more fatal in summer than in winter. On the contrary, when houses are closed and there is but little chance for ventilation, they prevail in greater severity. This is eminently true of typhoid and typhus fevers in New York; autumn and winter are the seasons for these diseases; and in summer they diminish. In these many respects, then, there seem to be broad contrasts between contagious diseases and cholera. And now, without attempting to exhaust this topic, I pass to another, adding, however, by way of explanation, that what I have said of contagion relates to emanations, vapors, or effluvia arising from the sick person, the dead body, the freshly discharged evacuations, and the fluids and solids of the body, as commonly exposed and handled in a post-mortem examination. I am not prepared to deny or to admit the doctrine that cholera is produced by the ingestion of minute portions of cholera discharges, though it appears to me improbable. I do not deny that the evacuations may become poisonous by fermentation, or that the soil and the evacuations may together produce the poison. One or other of these opinions, or the more vague idea, that in some undefined way the evacuations reproduce the disease, has taken possession of the minds of many ardent men in the profession; but a deliberate examination of evidence has shown, as it seems to me, that neither of the doctrines is fully proven. But admitting either one of them, even then the disease would be contagious, or infectious, if you prefer the term, only in a modified sense, not as typhus and small-pox are.

Although cholera is not contagious, it is portable, or at least its cause is. On this point will turn the wisdom or propriety of quarantine; and if I enter somewhat into detail in stating the facts which bear upon it, you will suppose that I am influenced by a desire that you should understand the question fully, and not prejudge it on the statements of those who have lost faith in this preventive measure, while at the same time you

acquire additional information regarding the habits of the disease. From our very first knowledge of cholera we have been familiar with the fact that it has marched from its home in the East along the great travelled roads; that it has kept time with the movements of travel, or at least has not out-marched it; that it has followed the lines of commerce; that it sometimes attaches itself to armies, and follows the course of their march over a large district of country, attacking certain towns and villages, and not attacking others in their course—thus discriminating because the conditions necessary for the regeneration of the poison exist in one and not in another. It has marched with caravans of pilgrims. Pilgrims from Mecca brought the disease into Egypt; and from Egypt it spread into various parts of Europe last year. It has marched with pilgrims from the East into Arabia. Indeed it is very generally asserted throughout Europe that only in isolated and exceptional instances is it found out of the line of travel and commerce; while Pettenkofer holds that no instance of supposed spontaneous origin will bear the test of close examination; that it always and everywhere in Europe originates in the action of choleraic evacuations upon the soil, these being discharged by a person arriving from an infected place, or by such a person travelling and leaving the noxious secretions on his way.

But the mode in which the disease crosses broad waters is more instructive. How, for example, did it first reach England? That country is separated from the continent by waters quite too broad to permit the wind to carry the poisonous principle from shore to shore; and as a matter of fact, the disease has first appeared there in regions where the sea is of the greatest width. The very first point invaded on the shores of England was Sunderland, near the parallel of 55°. To this place it was brought by trading vessels. The points where it has made its attack in every epidemic in England, except one, have been upon the eastern coast, and at one or other of the principal commercial towns, Hull, Sunderland, Newcastle; and in each instance the first cases occurred after the arrival of infected vessels. The same is true of its appearance at Edinburgh in Scotland, and at Dublin and Belfast in Ireland. It generally appeared in London only after it has made a landing in those more northern cities. In one instance, in the autumn of 1853, it occurred first in Liverpool, and a few days after at Newcastle, on the opposite coast. It occurred in Liverpool among the German emigrants who had just been landed there from Hamburg, where the disease was at the time prevailing. It was clearly carried there; it was in the ship during its passage from Hamburg to Liverpool. It soon became mildly epidemic in Liverpool, waiting, however, for the next warm season to become severely epidemic. Then it has crossed the Atlantic, and how? At one time it was fashionable to assume that the cholera marched by a certain steady progress; that it was caused by a great morbific wave rolling slowly and steadily eastward, and that it would envelop place after place at pretty regular intervals; but this opinion does not bear very close inspection. In its movements in India, at first its progress was about twenty-one miles a week; in its movements from the delta of the Ganges to Canton in China, going eastward, it travelled little more than ten miles in the week; when it reached Europe its progress was estimated at a greater speed, sometimes eighty and sometimes a hundred miles in the week; but a hundred was the highest figure assumed to represent its progress. Now dating from the time when cholera first appeared at Sunderland, in 1831, to the time when it first reached Quebec, and then in New York, the rate of progress would hardly be greater than that indicated by the highest of these figures; but in subsequent epidemics it has crossed the ocean at the rate of three hundred and fifty and four hundred and fifty miles a week. Then, too, it appeared in England before it had assailed the region intervening between Hamburg and the British Islands; and the question arises, if it depends solely upon any such atmospheric wave, why were these intermediate places exempted. Again, when it came to this country, it first appeared at Quebec and Montreal. If that wave had rolled across the Atlantic, and so reached these cities, it must have passed directly over Nova Scotia, New Brunswick, and the northern part of Maine; and yet no disease was found there until long after it had made its way to New York, and thence spread in various directions. But we find that the brig *Carricks*, and another vessel bringing emigrants to Canada, reached Gros Island, the quarantine grounds of Quebec, and thirty-nine miles below it, on the 3d June, 1832, having cholera on board, and that the emigrants of these vessels were taken by a steamer from the quarantine grounds; that some of them were landed in Quebec and some in Montreal; and in two days from the time this steamer reached each of these cities, that is, on the 8th and 10th of June, the disease broke out in those towns; and that it gradually spread to become a severe epidemic. Then how did it come to New York? It had now made a lodgment on this continent. On 10th of June it was at Montreal; June 24th it was in New York. Did it travel from Montreal to this city? That is the more common opinion. But if it invaded New York from Canada it passed over Burlington, Troy, Albany, and all the intermediate towns on its way, to return to them after establishing itself as an epidemic here. That was the day of steamboats and stage coaches. Railroads did not reduce the distance between Montreal and New York to a single day's journey. Travelling, though rapid then, was not so rapid as to make it probable on this supposition that these towns would have escaped. Dr. Vaché, however, states that the ship *Henry IV.* arrived in New York harbor with cholera on board, in the latter part of June. He makes this statement in 1850, and says he has searched for the records for the date of that ship's arrival, but could not ascertain the precise day, the volume in which the entry was made having been mislaid or lost. There is, then, a chance, a probability, that the disease reached us in New York as it reached Quebec and Montreal, directly from Europe, by emigrants or passengers; still, an affection that is transportable would hardly prevail long at Montreal without finding the means of extending itself to this commercial centre, so constant is the intercourse between the two cities. But if it came from the ship *Henry IV.* the mode of invasion would be in accordance with that of the subsequent epidemics in this country.

The history of the approach of cholera in 1849 is interesting. It began, indeed, in 1848. Two ships left Havre, one on the 31st of October, the other on the 9th of November, 1848. The latter ship, the *New York*, was bound for the city of New York. The first, the *Swanton*, was bound for New Orleans. The passengers in these two ships were of the same character, mostly German emigrants; they had been taken up in both instances at Havre, which port was at that time free from cholera. They had come to Havre for the purpose of finding a ship for this country. One report states that a portion of them had left infected places in Germany. The ships came out with a clean bill of health. The *New York* had been at sea sixteen days when cholera appeared—that is, on the

25th of November. The *Swanton* had been at sea twenty-seven days when the first case occurred, it being the 26th of November. They were one thousand miles apart. They were both off the coast of the United States, one in latitude 25° 47′, and the other on the parallel of 42°. The outbreak on the *New York* is by the captain of the vessel ascribed to the following fact: A very cold, chilly wind came up on the 24th, and the passengers found themselves in want of warm garments; in his own phrase, "there was a general overhauling of baggage for warm clothing." Then the next day became exceedingly hot, and on that day the first case of cholera occurred. On board the *Swanton* this cold day was not experienced; but, says the captain, "previous to the sickness, for twenty-four hours we were visited by a very hot south-east wind; such a one as I never felt before; indeed it was more like artificially heated air than anything else." Now, the question comes, where was the poison that produced this disease? Was there a layer of cholera-air stretching up and down the ocean, into which these vessels sailed about the same time? Such a supposition is unsupported by any other fact in the history of cholera, and is therefore in the highest degree impossible. The wind could have had no agency in the transporting of poison; for, during the interval of twenty-four hours which elapsed between the occurrence of the first case on board the *New York* and the commencement of the sickness on board the *Swanton*, the wind was blowing from the south-east, or nearly in an opposite direction. Then it would be waste of breath to express the idea that any animal poison could traverse a thousand miles upon wind. It seems to me far more probable that the poison was lurking in the baggage of these passengers, and that the emergencies which require the opening of unventilated trunks and packages, let loose in each of these ships that poison brought from the infected regions of Germany. There is, however, another explanation which is urged by those who have paid much attention to the researches of Pettenkofer and the Bavarian Commission. It is found in the period of incubation." This period, it is asserted, is long enough to admit the supposition that a person might receive the infection in Germany, then travel to Havre, embark and be at sea sixteen days, and after that have the disease declare itself in him. This would imply an incubation of above eighteen days, and it is claimed that it may be twenty-one, or twenty-five. But even this maximum requires a little extension to meet the circumstances of the *Swanton*. Twenty-seven days at sea and two days from Germany, would make an incubation of twenty-nine days, a period longer than has yet been claimed. Well, the two ships go on their voyage. One arrives in the harbor of New York on the 1st of December, six days after the outbreak, having lost seven of its passengers. The other goes into the Mississippi river and up to New Orleans, having lost several of her passengers, reaching the city December 11th. On that day, one patient was sent from the ship to the Charity Hospital. Two days after, a person not attached to the *Swanton*, but resident in the city, was attacked, and on the 15th eight persons were admitted into the hospital with the disease. This was the beginning of an epidemic which lasted during the whole of that winter in New Orleans, became more intense as the spring opened, and ascended the river from that place.

The *New York*, in the harbor of New York, discharged eleven sick passengers to the quarantine hospital, and the disease became locally epidemic at the quarantine grounds. The first person, not attached to the ship, who was attacked, was one who went on board the vessel and was seized forty-eight hours afterwards, dying the same day. A nurse who had had no communication with the passengers of the *New York*, as far as was known, was attacked at about the same time. Early in December, one of the passengers of the *New York* was attacked with cholera in the city and was sent back to quarantine. His room mate was also attacked. Both died. The disease did not spread in the city, but it became epidemic in the quarantine hospitals, so that among the steerage passengers detained, and the inmates of the hospitals, there were, up to the 28th of December, one hundred cases, one-half of which proved fatal. The disease seemed to have been checked by severe cold on the 1st of January, when it ceased. But it reappeared in the first week of April, 1849, and prevailed at quarantine for more than a month before any case occurred in the city. During the spring of 1849 several ships entered the harbor, having cholera patients, who were sent to the hospital at quarantine. Up to the 15th of August forty-one such persons were landed, and there had been in the hospital one hundred and ten deaths from cholera.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

ADJOURNED MEETING, MAY 9, 1866.

DR. JAMES ANDERSON, President, in the Chair.

MALIGNANT INFLUENCES OF THE UTERUS.

DR. GRISCOM, in a paper entitled as above, gave the details of two cases:

Case 1.—A lady aged 30, who had been married several years, and whose only child had attained her ninth year, consulted him with regard to certain symptoms, pointing in her view to the lungs as the seat of disease. She described her health as having been delicate for a while back, that her cough had become quite distressing; in short gave him a summary of the rational signs of phthisis. He found her much prostrated and suffering considerably from loss of sleep, to which her nervous excitability had subjected her. He could find, on auscultation and percussion, none of the physical signs of pulmonary disease; but by excluding the other organs, he was led to make a vagino-digital examination, and discovered the uterus in a condition of complete retro-flexion. The use of Simpson's sound and taxis *per rectum* effected restoration, which was further maintained by means of a horse-shoe pessary. All the symptoms then disappeared within a short period, and a robust infant was born within the year. In this case he was disposed to assign as the original cause for the displacement of the fundus a non-restoration of the tonicity of the muscular fibres of the uterus, which process was by some means delayed after the completion of her first labor.

Case 2.—A lady from Ireland, four months married, and in her twenty-second year, sought his advice for dyspepsia, with the usual train of symptoms, such as constipation, etc. The vomiting, tenderness over the epigastrium, and other symptoms, induced him to treat her for subacute gastritis by applications of croton oil and blisters, but without any good result. He at length discovered that the amenorrhœa, from which she had suffered since her seventeenth year, was co-incident with the constipation. She ascribed this derangement in the menstrual function to an unusual and severe exertion in leaping a fence to escape being injured by

a horned brute. Horseback exercise, for which she had something of a passion, doubtless also contributed to maintain the uterus in its deranged action.

On examination he found the *fundus* and *os uteri* nearly on a level with each other. He restored the organ and enjoined quiet in a recumbent position for a week. The result was a disappearance of the painful suspensions, which were wont to be the rule for three or four months at a time, and a return to her menstrual standard before the occurrence of the accident. The removal of all the other distressing symptoms also, added but another to the many instances of the controlling power of this organ in the female economy.

CONGENITAL ABSENCE OF THE UTERUS.

Dr. Chamberlain related a case which came under his observation at the Demilt Dispensary. The female presented herself several months ago at his class for Diseases of Women, with icterus, and anasarca, dependent upon albuminuria. Her condition requiring attention to physical wants as well as continuous treatment, decided him to send her to a hospital, from which time he had lost sight of her, until her reappearance at the Dispensary last week with secondary syphilis. He then found her with a general papular syphilide, together with the local manifestation of mucous tubercles. He discovered, on examination, also, that the vagina was a *cul de sac* one and a quarter inches in depth, the uterus absent, and the mons veneris and labia deficient. The mammæ were, however, fairly developed. She was herself altogether ignorant of her anatomical peculiarity. She affirmed that the sexual instinct was absent, but was conscious of a molimen at stated periods, from which he inferred the presence of the ovaries.

HYPODERMIC INJECTIONS OF MORPHIA.

Dr. Clark then illustrated the effects of hypodermic injections, by the recital of the following cases, recently under observation:

Case 1 occurred at the residence of a medical gentleman, in the person of a lady visitor. He found her with a cold surface, upon which there was present some perspiration, and with vomiting, as well as copious dejections from the bowels. She was restless, nearly pulseless, and apparently dying. Her condition indeed was looked upon by both as desperate in the extreme. He suspected that these exceedingly rapid disturbances—for the invasion was sudden—were due to the introduction of some poison into the system, and further inquiries elicited the fact that an over-dose of the saturated *tinct. rad. aconit.* had been taken. This had been prescribed some six months before by the medical gentleman alluded to, in five-drop doses, to be taken after dinner, with the usual caution against exceeding the directions. But the patient, while in a hurry, had poured out into a teaspoon and swallowed an unestimated quantity of the medicine, with the results as just described.

Stimulants, with a view of bringing up the heart's action, were then suggested to both, and owing to the gastric irritability, an injection *per rectum* was accordingly given, but immediately returned. They were then driven to anodynes as their next resort.

The hypodermic syringe, charged with fifteen drops of *Magendie's sol. morphiæ*, was tried, when, after the lapse of some fifteen minutes, the vomiting ceased, the pulse returned, the hands became warm, and a gentle slumber was induced, which lasted for two hours. Then another portion was introduced, which carried the patient through a period of quiet to the morning of the next day, when, at eight o'clock, he found her suffering from nothing but nausea.

Case 2 was, in its bearing upon this question of endermic medication, rather adverse. A patient, who had been the subject of an instrumental labor, was received eight days afterwards into one of our public institutions for the purpose of being treated for a decided trismus, accompanied by a spasmodic action of the limbs. To produce quietude and sleep, of which the patient was in much need, the house physician had used, but without effect, fifteen drops of Magendie's solution of morphine, endermically applied. This treatment he had himself ordered to be continued, according as the condition of the patient, who was to be visited every two hours, might warrant. The instructions were faithfully observed, and some four or five injections, varying in quantity from ten to twenty drops, at intervals of two to two and a half hours apart, employed. At 2 A. M., the physician finding her still unaffected by the narcotic, her spasms unrelaxed, her intellect clear, and as far as her nervous system was concerned, as sleepless as ever, again injected twenty drops of the solution. The nurse in attendance states that the physician had scarcely left before the patient fell asleep, but that supposing everything was going on well, she refrained from reporting her condition. On a succeeding visit, she was discovered profoundly narcotized, from which state she could not be aroused. The points into which the solution was introduced were carefully dissected, but only around the last one was there remarked an ecchymosis, from which the inference was drawn that the injection was sent directly into a small vein instead of being introduced through the more indirect medium of the areolar tissue. The action of the morphia was, in consequence, more prompt. There was likewise found a laceration of both the uterus and vagina, besides some adhesions, which shut in a certain amount of pus, the results of inflammatory action, but there was no general peritonitis. Before commenting upon this issue, he would preface it by another statement, that a case is recorded where the sister of a physician became the subject of some three thousand of these injections within the year, without any unpleasant result. Still, these possible accidents were to be considered; in fact, a physician in a neighboring state had informed him of the occurrence in a single season of three fatal cases ascribable to the adoption of this method.

Dr. Bacheldor had been in the habit of giving opium in tetanic cases, and looked for its effect in from fifteen to thirty minutes; should none then be produced, he had no hesitation in repeating the dose. He was also wont to watch for the nose-itch, which he regarded as the very earliest announcement of approaching narcotism. As a safeguard against accidents in these hypodermic injections, he would suggest a pinching up of a fold of the skin and the simultaneous introduction of the syringe.

A CASE OF PURPURA HEMORRHAGICA.

Dr. Bulkley had about a month ago attended a case of which he gave the following summary: A lady, aged about 23, married on a Thursday, was on a visit to the city and had put up at the Astor House. Her health remained as good as usual, until Sunday, and then only a certain yellowness of the skin, supposed to be that of jaundice, was remarked. On Monday, she breakfasted at the hotel table, when her husband noticed some redness at the tip of the nose. During the forenoon of that day she was attacked with nausea, vomiting, and some diarrhœa. She also threw up a dark fluid resembling blood, and passed blood from the bowels. Although urged to seek medical advice during

the day, she declined doing so, and was not accordingly seen by him until 10 o'clock P. M. Delirium, incessant jactitation, ecchymosis of the eyes, a pulse almost incapable of being counted, the nose markedly cold and of the hue of deep red wine-lees, together with a streak of the same color, which did not disappear upon pressure upon each side of the cheek, then severally formed the prominent features of her condition. During his attendance, which was continous, he ascertained that there was hæmorrhage from the vagina also. His prognosis was unfavorable from the first, but by the free exhibition of stimulants, as well as of external applications, her surface resumed in a measure its natural temperature. The pulse also rallied somewhat and became variable, ranging from 118 to 140, 150 and over. She finally rejected both stimulants and food, and died on Tuesday at 5 A. M. seven hours after he had first seen her, without any manifestation of coma during the progress of the disease. The case he thought remarkable for the rapidity of its termination. He recognised at once the symptoms of a malignant disease, and suspected that it was purpura hemorrhagica, complicating variola, of which he had seen several cases, and all of which had proved fatal. He therefore searched carefully for evidence of an eruption, but could find nothing to satisfy him. He had, however, subsequently heard from her husband that small-pox had been prevailing in the town where she lately resided, and also that she had been in the city a fortnight before her marriage.

Dr. Clark recalled a case where death had ensued in a single day, but it was after the disease had fully declared itself. Two other cases, which terminated fatally in five days, he had also seen in connexion with Dr. Bulkley.

The Academy then adjourned.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, May 7, 1866.

Dr. Thos. C. Finnell, President, in the Chair.

The President announced that the *Comitia Minora* had voted to grant certificates of membership to Drs. Wm. V. White, Edward H. M. Sell, William B. Lewis, Edward S. Dunster, Charles McMillan, and John O'Reilly.

Dr. Field, of the Committee on Diseases, reported that the mortality for April was less than in April, 1865, and that, with the exception of a slight tendency to pneumonia and rheumatism, there was no evidence of any prevailing epidemic. Two cases of cholera had occurred during the month, the histories of which were fully related, but the diarrhœa which usually precedes a visitation of this disease was almost entirely absent. The death of an old man at the advanced age of 106½ years was mentioned. The deceased was a native of Ireland, and although he had always been in good health, he died in the full belief that his days had been shortened by removal from his native land.

THE DEATH OF PROF. JOS. M. SMITH, M. D.

The President having announced the death of Prof. Joseph Mathew Smith, a member of the Society since March 13, 1820, a resolution offered by Dr. Stone to appoint a Committee of three to prepare and report suitable resolutions, was unanimously adopted. Drs. Detmold, Stone, and Bulkley were appointed, who subsequently recommended to the Society for its adoption, the following preamble and resolutions, which were unanimously adopted, and the Secretary was directed to have them published in professional and secular prints:

Whereas, Death has removed from among us our beloved and revered colleague, Doctor Joseph M. Smith; therefore,

Resolved, That while we bow in devout submission to this dispensation of Providence, we deeply mourn the loss of one to whom many of us have looked as a beloved preceptor, most of us as a tried and safe counsellor in difficulties, and all of us as a bright example of a distinguished and good Christian Physician.

Resolved, That while we tender to the bereaved family the assurance of our respectful and sincere sympathy, we may be permitted, for their comfort and consolation, to point to the long and well-spent life of the departed, the like of which is vouchsafed to few men; for he has died ripe in years, and rich in the love of his fellow-men.

Resolved, That we will ever cherish the memory of Dr. Joseph M Smith.

Resolved, That a copy of these resolutions be sent to the family of the deceased.

CHLOROSIS.

Dr. William H. Thomson then read a continuation of a paper on chlorosis, introducing the subject by narrating the history of a patient whom he saw in consultation, whose affection terminated fatally after nearly five months of suffering, from a train of singular symptoms which followed a sudden suppression of the menses, induced by exposure in a cold rain storm. The first trouble complained of was a persistent constipation, attended with anorexia and a great amount of noisy flatus in the intestines. This constipation resisted every cathartic exhibited, until finally stercoraceous vomiting set in, with great irritability of the stomach and other symptoms usually distinctive of mechanical obstruction of the bowels. After a time, however, cathartics would act occasionally with some freedom; but the color of the dejections indicated a complete absence of the bile, being as white as lime plaster, though as a rule, the intestines propelled their contents in the wrong direction, so that finally the poor girl was fed by enemata while she defecated by the mouth. Soon afterwards a like extraordinary reversal took place in other glandular organs. The urine (always when flowing loaded with biliary compounds) became suddenly suppressed, whereupon the salivary and lachrymal glands ran profusely for two, three, or four days in succession, until they also stopped for a few hours, at the end of which the bladder was full of urine, and this alternation between the kidneys and the parotids went on about twice a week for two months, generally concomitant with the analogous misbehavior in the alimentary canal, until the patient sank. Post-mortem examination revealed no mechanical obstruction in the alimentary tract, but instead, the mucous membrane and other coats of the intestines were reduced to an apparently single thin and transparent tissue.

Few, we think, who could have watched this case for weeks together would have doubted that these symptoms, extraordinary as they were, had for their original cause the suppression of the menses. It was an extreme case of a common affection, which consists in a peculiar disturbance of the particular system of nerves which secures and regulates that association of action between the many divisions of the nutritive organs, without which the component elements of the blood will fail to be elaborated. This affection has been unfortunately named chlorosis, after one of its least essential symptoms, a symptom necessarily absent in this case, for the patient never looked yellow or yellowish-green, as she happened to be a red Indian. Her malady, therefore, though exceptionally severe, was yet of the

same nature with many other cases, which, starting with a suppression of the menses, show first an arrest, and lastly a thorough perversion of the natural harmony of action between the various nutritive organs and glands.

We believe that without a clear apprehension, as a preliminary, of the regulated association in action between the many apparently independent glands and organs concerned in nutrition, we will fail to get clear views on the pathology of the affections classed under the terms, anæmia, chlorosis, hysteria, et cetera.

The general features of that inter-association, when derangements are often so perplexing, are these—first, as to the process of digestion. No sooner does a particle of food enter the mouth, whose glands at once respond to its excitation, than we find the same excitation propagated through set channels further down to secure for the savory eatable its right reception wherever it travels. The physiologist shows us what the preparation is when we find that with a hungry dog, in whose stomach a fistula has been established, the sight of a slice of meat causes an immediate flow of gastric juice from the wound. We might, therefore, say that on the entrance of every morsel each section of the alimentary canal is literally telegraphed to prepare for adequately dealing with what is coming. With the order comes also not only the requisite supply of blood, but, besides, a supply of vital power for the performance of the duty demanded. Let a gland receive through its appropriate channel the order, and all its vessels dilate, its circulation quickens, and its cells multiply, until even the veins which proceed from it pulsate, and bring away red blood. It is on account of this regulated inter-association that the state of the tongue often affords us a good criterion in judging the general nature of an affection which may reside perhaps thirty feet off in the course of the canal. But let that telegraphic order fail of reaching its destination, or let it be sent to some other part, or let it be interrupted altogether, owing to some derangement of the wires, and the immediate consequence is deficient, suppressed, or perverted proper action, whether of secretion, absorption, assimilation, or excretion. The blood-vessels will not dilate, the cells will not form, and a natural secretion will not flow, be the arrival of nourishment what it may. To maintain, therefore, true nutrition, we need first to maintain that regulated balance of life, that living influence which ceaselessly traverses back and forth from one organ to another, evolving the beautiful order and coöperation which are more wonderful than all the circular movements which the astronomer studies.

The source of this wonderful influence which presides over the infinitely varied processes of animal growth, which coördinates most diverse operations, and secures that consentaneous action which makes each perform its duty in the requisite time and manner, is derived from that most interesting part of the nervous system, well named by the old anatomist, "the great sympathetic." Its close connexion with the arteries shows how throughout the body the ever-changing distribution of the blood is by it controlled and directed according to the need of each vital act, while its ganglia or special centres are to be found near every great organ whose intermittent function demands very various diversion of force and blood, according to its state of action or rest. In the harmony of health, we find the whole process carried on through certain set channels of excitation, and, therefore, we would define chlorosis as not merely and primarily what it is termed in a leading medical work—a blood disease occurring in young females in whom the menstrual flux has been interrupted, but a disease which, beginning with a serious irritation of the ovarian plexus happening during the crisis of the chronometrical performance of one of the most important processes, soon involves through the ganglionic system of nerves every other function to whose due action the process of blood-making owes its perfection. The propagation of this irritation will, if not checked, extend to the arrest or perversion of every function in systemic nutrition, through a suspension by that irritation of the normal current of nervo-secretory excitation

This view of the nature of the primary lesion in chlorosis seems substantiated by the general change in the views of the profession as to the significance of the menstrual flux itself. The former conception of the uterus acting at such periods as an eliminating gland to remove from the system a certain quantity of too highly carbonized blood, has been abandoned, as it became clear that the essential elements of the process are to be found, not in the uterus, but in the ovaries, and that the natural flow is no more a proper uterine secretion than an epistaxis is a nasal secretion. The influence of the old view is still apparent in the therapeutics, from the means usually sought to simply secure a flow of blood, as if that constituted the whole cure in a case of suppression, though there are perhaps few practitioners who, after obtaining by the stimulating emmenagogues a fair return of the flow, have not been often disappointed by a persistence of ill health. Menstruation is not due to some excrementitious material which nature cannot get rid of only by rupturing the capillaries of the uterine mucous membrane, for ovulation and not bleeding is the essential thing, and it is to the conditions presiding over this great function of life that our attention should be directed.

How serious a sudden interference with the process of ovulation may be we can readily conceive from the peculiar relations of this region of the body, in both sexes, to the general vitality of the system, and which can be explained only through its intimate connexion with the sympathetic. No one can fail to be struck with the extraordinary susceptibility of the whole organism to any injury in this part, for we must certainly be near a vital point when we find that the most sparing and careful divisions of the knife, through which a calculus in the bladder can be removed, prove, nevertheless, more perilous than the sweeping cuts of operations on the extremities or face. It is not, therefore, the wound in the fibrous, muscular, or membranous tissues, with which the system sympathizes so profoundly, but because here is a centre of animal life, connected not alone with the physiology of the individual, but of the species. It is therefore not difficult to conceive that, with such an intimate connexion with one another, between the abdominal viscera and the relations they hold to vitality, it is primarily a lesion of the sympathetic which initiates the various disturbances of chlorosis, that end in paralysed digestion and impoverished blood. The primary irritation of the ovaries first suspends the normal chronometric increase in the pelvic circulation by shutting off the requisite nervous influence; but soon we note derangements widely removed as to their seat, but not as to their nervous connexion with the pelvis. The entire alimentary apparatus, from beginning to end, commences to act strangely. First of all, the nervous sensation of hunger disappears, to be replaced perhaps by the most curious and capricious manifestations indicative of perverted nervous transmission. The stomach frequently rejects food, or deals with it most uneasily. The liver equally fails in its action, as shown by the scanty and light-colored discharges. The secretions of the whole intestinal canal change in character. The nervous paralysis shows itself in a persistent constipation, owing to suspended peristaltic movements. The

nervous irritation does not confine itself only here, for the derangement in the distribution of the circulation is apparent in the cold feet and hands, while finally, as a natural result of these initial derangements, the formation of the blood becomes impeded, and we have the peculiar anæmia which was formerly considered the cause rather than the effect of this disease.

We have dwelt thus long on the pathology of this affection, because of the necessary connexion which such views have in determining the measures which we should adopt for its treatment. Thus, in the first place, the nervous in contrast with the hæmatic view of the pathology of chlorosis, would lead us to pay early attention to the persistent coldness of the feet, so generally complained of in these cases. Were this the result simply of poor blood, we should find it in the anorexia of phthisis, or cancer; but there is something distinctive in this symptom of uterine disturbance. In a case of displacement of the uterus, in a lady past middle age, caused by lifting, I found almost complete suspension of circulation suddenly occurring in the whole lower extremities, which passed off and warmth returned in a few moments after replacing the organ. That the distribution of the circulation in widely separated parts of the body is regulated according to nervous impressions, which are restricted to set channels, is too well known to need our citing more than one illustration. Brown-Sequard has shown that if a piece of ice be held in the palm of one hand, a thermometer held in the other hand will immediately show a decrease of temperature in that hand, which is not owing to the ice having cooled the whole body, and therefore the hand which holds the thermometer also, for thermometers placed in the axillæ manifest no change. The hand which had no ice was therefore cooled only from its nervous connexions with its fellow. Now, as injury at the nape of the neck affects the pupil of the eye, and cold applied there arrests an epistaxis, so will the impression of cold applied to the feet affect first the ovarian plexus and suspend the local determination of blood necessary to the function of ovulation; but also, *vice versâ*, let irritation be located in that plexus, and the circulation in the feet is sure to be impeded, while in other parts, as the head and face, the patient will complain of flushing heat and throbbing temples. We believe, therefore, that it is of real practical value to persistently endeavor to restore this disturbed balance of the circulation, for we have never seen a case of chlorosis that did not at once improve if the feet were kept warm for one whole day. This symptom often precedes for months every other of the more recognised signs of disordered menstruation, and we have often found that by attending to it alone we have markedly relieved other common female ailments, especially dysmenorrhœa and leucorrhœa. Our usual measures for this purpose have been a hot pediluvium, acidulated slightly with nitro-muriatic acid, at night; then in the morning to have the feet and legs rubbed with warm olive oil, which friction very soon causes to be absorbed so as not to soil the clothing in the least; and lastly, the old woman's remedy of rubbing black and red pepper in the stockings. The foot-bath should be as hot as possible, to escape the weakening influence of merely warm water, and secure the stimulating influence of heat, which is the only agent to be desired in such a case; nor, after the protective use of oil, have I found any increased susceptibility to catching cold from this treatment, though kept up for a long time.

Beginning with the other functional derangements in the order of their appearance, we come to the measures taken for the restoration of the appetite, and we would only remark that in the anorexia of females we have found no agents to compare with the mineral acids. We have repeatedly disgusted such patients with bitters, with no other result than no very pleasant feeling on their part towards physicians prescribing such disagreeable medicines. These patients, however, often crave sour things; and the nitro-muriatic acid especially, I have found to answer admirably. It may be recollected then, in the history of the case detailed above, we found this acid to produce a really tangible cholagogue effect, and I have no doubt that its reputed property of stimulating the liver has a substantial basis, and that its failure, as there stated, is generally due to the defective quality of the preparation. If so, this, taken in connexion with the torpidity of the liver in this disease, would seem to recommend its use, while it can hardly do any harm.

Constipation is another main symptom, and one of the most important of all. Some one has defined a woman as an animal who always has a pain in her side, and locked-up bowels. We have already adverted to the probable cause of the latter common sorrow of the sex—namely, nervous paralysis or deficient peristaltic action. But we cannot, on that account, fall in with the common practice of the use of cathartics in the treatment of chlorosis, except to a limited degree. We think this end can be reached, especially in weak and anæmic patients, without recourse to any exhausting discharges. We are not called in chlorosis to eliminate anything; and while small doses of aloes are undoubtedly beneficial, we regard that as owing more to their stomachic and stimulating effects than to their cathartic properties. Some physicians speak of the necessity of washing away by catharsis the slimy mucus which lines the intestines in these cases, and prevents the absorption of aliment; but if it was possible it would immediately form again, if the intestinal glands remained in the same condition as before. The agent which has oftenest given me satisfaction in relieving this, perhaps the commonest complaint addressed to a physician, is belladonna. I was led to try it by an article on its laxative properties by M. Hirtz, of Strasbourg, to which I paid the more attention from having noticed that its prolonged use had induced looseness of the bowels in three patients of mine, to whom I had administered it for nervous diseases; one of which, a male, had epilepsy, and another, a female, an asthmatic affection dependent on cardiac disease. M. Hirtz ascribes its laxative power to its relieving spasm of organic muscular fibre, which is owing to nervous irritation, and that in this way it relieves in women the constipation which is dependent on deranged nervous action from organic disturbance. However that may be, I think it will often prove a valuable remedy in such cases, without any disadvantage like inducing either exhaustion or interference with appetite. But in addition to belladonna we have another agent which, though not classed among cathartics, yet in these cases answers the purpose still better—namely, nux vomica. Owing to its reputed property of stimulating peristaltic action, it has been often administered for this purpose, and I have no doubt that it is of real advantage, and that it does not interfere in the least with the action of belladonna, but that the two rather coöperate to the same end. To secure, therefore, a natural and regular action of the bowels, with slight catharsis after prolonged inaction of the bowels, I have been accustomed to prescribe at night one pill, compounded of extract belladonna, gr. ¼; ext. nucis vomic. alcoholic, gr. ss.; extract colocynth co. gr. iij. In a few cases a second pill in the morning is necessary at first to induce the bowels to act; but soon one is found in my experience to be sufficient, and I have tried it now in a sufficient number of patients who had long used other means ineffectually, to make me quite confident of its benefit.

Of the other therapeutic measures for such cases which suggest themselves to all physicians, I will not now speak, except to refer briefly to the use of iron. This remedy, which has become routine because so valuable, is like all routine remedies, often given with poor if not bad results. One great reason of this is, I think, owing to the faulty way in which the mode of its action is explained to the medical student. He is told that chlorosis is a disease in which the red corpuscles are deficient. Iron is a part of the red corpuscle—therefore the real logic of the case, as put to the student, is—give iron and you will have red corpuscles. After the same fashion it was formerly reasoned, that to cure rickets, which consisted in a deficiency of phosphate of lime in the bones, give phosphate of lime. But such attempts are not a whit more reasonable than the Irishman's plan of having his cow milk ice-cream, by feeding her with a bucket of snow. Let all the iron possible be sent down the œsophagus, and if it is not digested, absorbed, and then assimilated as systemic food, just as the albuminous part of a beef-steak is, then it had better been introduced into the patient's pocket than into his stomach. For a particle of iron to become part of a red corpuscle, it has to be submitted to a vastly more complicated process than is requisite for a piece of that metal to take its place as a mainspring in a watch; and it is no more reasonable to suppose that we can remedy anæmia simply by administering iron than that we could mend a watch by putting it near a bag full of watch-springs. Something has to come between in either case to make the iron fit. We repeatedly see the administration of iron followed by anything but cure, and perhaps the main cause of failure is from the overloading which the mechanical physiology above alluded to induces. We would naturally expect a starved patient to be distressed with unexpected bounty which required him to dispose at one meal of ten times as much meat as he ever ate when he was not starved, but that is not relatively greater than is fifteen grains of solid iron a day made skilfully soluble by modern chemistry. In a healthy state all the iron which the blood needs reaches it in such infinitely divided and small doses through the food, that it would require a delicate test or scale to compute its daily renewal, nor do we believe it can ever become part of a blood corpuscle without coming in that shape and quantity. Meanwhile we administer it to delicate females with weak powers of digestion, giving them with each dose enough to last a month, and we need not wonder at the blackened fæces which show us where our iron is, nor at the nausea, headache, and dyspepsia which we have induced. In our experience two grains of the citrate of iron, combined with tincture of nux vomica and tincture of quassia in glycerine, act more speedily than ten grains, and with much more comfort to the patient.

We would allude, in closing, to but one other agent, and that is phosphorus. This administered in the form of four grains dissolved in one ounce of olive oil, of which the dose is from ten to fifteen drops, has, we think, oftentimes proved of essential service. Its chief effect we are disposed to attribute to the powerful influence of this medicine in stimulating the circulation. It is a favorite remedy on this account with me in the treatment of epilepsy, in which disease I think I have noticed a habitual weak state of the pulse during the apparently healthy interval between the attacks. In chlorosis I think it acts by restoring general circulation and heat, and only indirectly as a local excitant to the pelvic organs. But in my experience it is only the substance itself in solution which has these properties; and when given as above directed, I think it is a perfectly safe agent. Phosphoric acid seems to me to be almost inert, while of the hypophosphites I have no experience in these affections. In reference to the local or stimulating emmenagogues, such as the terebinthinate class, I have very little faith in their being more than adjuvants, to be used both cautiously and sparingly. It is not a flow of blood that we so much need, as a restoration of the chronometry of life; and without a vast renewal of this, the most striking phenomenon in the deep laws of nature, we will accomplish little though our efforts ended in a great show of blood.

Dr. Peaslee spoke of Dr. Thompson's paper as progressive, containing some new points, and those not new were put in a very practical way. It was very important that the feet should be kept warm, and this might be accomplished by immersing them in cold water every night at bedtime. The susceptibility of the system to the effects arising from exposure to cold might by this method be greatly diminished. An intelligent woman, aged sixty years, was sorely troubled with a bronchial irritation which could thus be prevented, but would return whenever the cold pediluvium was discontinued.

When there is constipation of the bowels, the liver should generally be acted upon. A pill given three times a day, compounded as follows, he had found useful:

℞ Extract. Belladonnæ, gr. ½; Ext. nucis vomic. alcoholic., gr. ⅙; pil. hydrarg., gr. ij.; ext. colocynth co., gr. j.—jss.

In some cases extract. aloes aquos. might be advantageously substituted for the colocynth. Iron, as usually given, was injurious. Our posology was derived from the English, and one-half the quantity mentioned in their works was generally amply sufficient in this country. The tinctura ferri chloridi might be given in five-drop doses largely diluted with water. The syrup. ferri iodidi, in the same quantity, ten drops of this being a large dose. The best chalybeate in this disease was the ferrum redactum, in doses varying from gr. j. to gr. iss., never exceeding gr. ij. One-sixth of a grain of capsicum might be combined with it, and in cases of nervous excitability, extract of hyoscyamus.

Dr. Chas. F. Taylor then read a paper on

"THE INITIAL CAUSE OF LATERAL CURVATURE OF THE SPINE."

The term "initial (or real) cause," is used for the purpose of drawing the attention from the *immediate* cause, which would be apparent to any ordinary observer—muscular weakness.

There are several varieties of lateral curvature produced by different causes, such as rachitis, paralysis, local arrest of development, reflex spasmodic muscular action, distortion of the limbs or joints; in fine, anything which disturbs dynamic equilibrium. Without noticing in this paper cases produced by such causes, we shall consider those other cases, which probably amount to four-fifths of the whole, and which owe their origin to a common cause.

A girl of twelve or fourteen years, in fair health, is found to have one shoulder higher and projecting further backward than the other, and the spinal column is seen to be more or less bent to one side. Here the apparent cause is weakness of the spinal muscles. There can be no doubt but the column bends by reason of the superincumbent weight being greater than the muscles can support. But what causes these muscles to give out? Not because of any weakness in themselves. Nor can the distortion be looked upon as actual disease. The spinal column is mechanically, not pathologically affected. Its muscles fail to give it adequate support for the

weight resting upon it, and consequently it bends; and if the weight continues long enough without adequate support, it remains bent. So much for the spinal column. How is it with the muscles? They are not the immediate cause of the curvature, are not in a pathological condition. Indeed, the form of curvature we are now considering, often occurs where there is every evidence of active nutrition and growth. To one source only, then, can be traced the *initial* cause of lateral curvature—the nervous system. The muscles fail to give support to the column from deficient innervation.

We find that these curvatures generally begin from the twelfth to the fourteenth year, or in other words, at the period of most rapid growth; and it is noticeable that those growing with the greatest rapidity are most liable to curvature. Then besides the growth, which is an exhausting process, both in vegetable and animal life, the girl, as she approaches puberty, finds all her powers taxed in no small degree to fit her for those special functions which she shall be called upon as a woman to exercise. But nature is kind if she be only allowed sufficient time for her work. And nature has decreed that a certain portion of life shall be devoted to growth and development. Now, as a very general rule, we find the subjects of lateral curvature living amidst the friction of intellectual and refined society. The brain and nervous system are strained, and the physical powers are subordinated to the mental. Unless this order be reversed, the patient will suffer. It is not too much to say, indeed it is the real truth, that *the lateral curvature begins in the brain.* Dull and stupid girls do not get this form of curvature. The school-girl's *position* has much less to do with lateral curvature than is generally supposed. It is rather her close attention to study, at a time when she has little nervous power to spare. If a law could be enforced that no girl should attend school from twelve to fourteen years of age, we should see few crooked spines in girlhood, and hear much less of "spinal irritation" and backache in after life. In prescribing for these cases of incipient curvature, in very many cases the directions have simply been to take the girl from school, have her lie down much of the time, avoid study and excitement of all kinds, do nothing, think of nothing, keep quiet, and grow. In a few months the patient would return entirely cured. It is the rule that if we can get the cases in their incipiency, before the osseous structure has become hardened, and if we can protect them from waste of nervous force, we can rapidly cure them. The difficulty is to make parents understand the great necessity for this protection. Mothers will hold up their hands in horror at the idea of one or two years spent away from school. But this direction must be insisted upon. There is no room for compromise here. We must be absolutely inflexible in our demands The mother and daughter should be told that it is not intended to abandon, but only to interrupt, the mental activity, until nature has had time to gather up her forces, when the brain-work may go on again with impunity. But if we temporize at this stage, and wait a year or two hoping that the patient will outgrow the trouble, it will be too late; we cannot then cure, we can only palliate. If, in this early period, while the bones are soft and elastic, the debility, as manifested in the curved spine, be not removed, the patient's health may afterwards become ever so robust, but nothing short of long, tedious, forcible effort will bring back (and that not perfectly) the spinal column to its proper position.

The Society voted that the papers read by Drs. Thompson and Taylor should be the special subject for discussion at its meeting of June 4, 1866.

The President announced that Dr. Alonzo Caulkins would at that meeting read a paper entitled, "Dysentery without the Intervention of the Doctor—A case."

EAST RIVER MEDICAL ASSOCIATION.

ADJOURNED MEETING, MAY 10, 1866.

DR. JOHN HART, President, in the Chair.

DISCUSSION ON MENINGITIS.

DR. TRUMAN NICHOLS, in behalf of the delegates from the Association to the *American Medical Association*, gave a summary of the proceedings of that body, and warmly eulogized the hospitality of their hosts at Baltimore.

Dr. WM. NEWMAN then opened the discussion on *Meningitis* according to previous appointment. He remarked that *tubercular meningitis* was by no means a rare disease in childhood. It was then that the brain, stimulated by impressions as yet novel, cannot be otherwise than expected to take on an occasional deranged action. The disease most frequently occurs between the period of dentition and the age of five years. The base of the brain shows the greatest amount of inflammation; and beneath the *arachnoid membrane* there may be some softening of the cerebral surface, accompanied by chalky white lines along the upper portion, to which the element of increased vascularity is superadded.

According to Professor Alonzo Clark, the characteristic lesion in the acute form of the disease has the appearance of a number of small whitish grains on the membrane at the base of the brain. These are supposed to be tubercles, and are composed of a fibrinous material. Children of a strumous diathesis, either inherited or acquired, are most liable to be attacked by these tubercles, which, aroused from a condition of dormancy, eventually originate effusion. The diagnosis may be confounded with fever of the *remittent, intermittent,* or *continued* type. Attention should be directed to the tongue, which in meningitis remains moist; to the pupils, which are dilated; and to the bowels, which are almost invariably costive. The usually pale face, occasionally lighted up by a bright red spot on one cheek, perhaps stridulous breathing, a marked photophobia, and an unexpected convulsion, change suspicion into the conviction that a dreaded enemy is aroused to action. The pulse becomes irregular, the patient drowsy and inclined to extend its head back upon the pillow and at the same time to roll it from side to side. The clenched hand with thumb turned inwards towards the palm, and vomiting more or less severe, are also valuable signs.

With the increased pressure consequent upon a further accumulation of fluid, the symptoms become aggravated, strabismus may appear, the convulsions increase in frequency and violence, and paralysis, complete or partial, supervene.

Professor Clark says that not more than one in six cases recover without some physical derangement, chiefly of the sight or hearing, but the functions of these may be restored after a few months.

The treatment consists in an evacuation of the bowels by enemas; leeches to the temples or behind the ears; cold affusions or evaporating lotions to the head, warm pediluvia, sinapisms to the feet, calves of the legs, and inside the thighs alternately; warm baths, antimonials, and diuretics; calomel from 5 to 10 grains, followed by smaller doses of from 1 to 2 grains every two, three, or four hours, until the total of 20 grains in all shall have been attained; croton oil, rubbed up with calc. magnesia from ½ to 1 drop every two hours, until the bowels freely respond; and the iod. potass., which after all is the

only reliable diuretic in these cases, may then be administered, in doses of from one to five grains every two hours.

In the comatose condition, pustulation by well diluted croton oil or the ung. tart. antim. et potass., may be resorted to, with perhaps some benefit. A quiet, cool, well ventilated chamber should also be insisted upon. He had witnessed surprising and gratifying results, when he wished to procure sleep, from the ext. hyoscyami, in doses of from a ½ to 2 grains every two, three, or four hours.

Dr. N. then closed with a graphic summary of the symptoms and diagnosis of the meningitis of adults, indorsing blood-letting in the acute form as a valuable therapeutical agent; but enjoining caution in the use of this remedy in the subacute form. He passed in review the claims of calomel and croton oil in purgative doses, iod. potass., and the agents before alluded to.

When meningitis was a complication of Bright's disease, not much could be expected from any remedy; but he would in particular ostracise the iodide of potash.

Dr. Abbot adverted to the peculiar sighing respiration, which in the infantile form of the disease he regarded as a pathognomonic symptom. His experience had convinced him that small repeated venesections were by no means as effectual as one strong full bleeding, and this plan Dr. Marshall Hall vigorously advocated. He also alluded to the method of mercurial inunction applied to the scalp after extensive vesication. This was recommended by a recent writer, but he had known of no instance where the plan had been adopted.

Dr. Skiff had found, when the second stage had fairly set in, that the cod-liver oil, especially where the tubercular element was present, had given results quite satisfactory.

Dr. Newman was in the habit of using the article in the cases of all children convalescing from depressing diseases. In reply to an inquiry of Dr. Morse, he stated that cream, when attainable, was equally good, and that he did not endow the cod-liver oil with any specific virtues. Besides, as far as results were concerned, the oil derived from the "head matter" of the whale, and quite extensively sold for cod-liver oil, was more generally given than supposed. He would rely upon very few experts in the detection of this fraud.

Dr. Hart had noticed among the symptoms of the disease in children, that described by Eberle under the quaint designation of the "odor of mice." He had found when anodynes were admissible that the ext. hyoscyami, particularly in combination with camphor, had been none too highly extolled by Dr. Newman. He also valued the pill of calomel, digitalis, and squills, as an excellent diuretic, but was disposed to be rather sceptical of the virtues of the iodide of potash.

Dr. Nichols dissented to this last view of Dr. H., but deemed hyoscyamus to be much more reliable in its effects than conium, which many used. Warm fomentations assiduously applied over the region of the kidneys, he had known to be followed by a copious renal secretion.

A CASE OF SUPERFŒTATION. (?)

Dr. Abbot related a case, which had recently occurred in his practice, where, immediately succeeding a delivery of twins, a well preserved three months' fœtus was born.

Dr. Burke was of the opinion that this was an instance of arrested development, unattended, for some reason, by decomposition, rather than as might be inferred of superfœtation. He recollected a case which had occurred quite early in his practice, where there was an interval of three months only between the births of two full term children. This anomaly was found to be owing to a double uterus.

The meeting then adjourned.

Erythroxylon Coca.—Dr. Reis, in the *Bulletin Gén. de Therapeutique*, of Feb. 28, 1866, writes with regard to the Erythroxylon Coca:

"In January, 1863, as some of my colleagues may remember, I published an account of some experiments made with the leaves of the *erythroxylum peruvianum*, *erythroxylon coca*, a plant which is used by the Indians of Peru as a masticatory, in doses of fifteen to twenty-five grammes daily, for the purpose of enabling them to undergo fatigue, hunger, and thirst, or the severe labors of the mines.

"I have subsequently verified the powerful yet inoffensive efficacy of this substance as a nervous stimulant. On the one hand results are augmented, and continued activity of the mental faculties, rendering elocution easy and animated, and inspiring resolution, courage, and perseverance; on the other, an increased disposition to muscular action as shown by facility in locomotion, which can be continued without fatigue for a long period during the mastication of the coca. Hence, my observations have led me to regard this stimulant as an agent well adapted to distract the mind from its habitual cares, and sustain temporarily the vital forces, with or without a moderate use of food. Doses of two, three, or four grammes of coca, renewed at seasonable intervals, are sufficient to produce these physiological effects.

"The experiments of MM. Gorse and Mantegazza have, however, shown that in large doses the Peruvian leaf causes an acceleration in the cardiac contraction four times greater than that produced by tea, more than twice as much as that resulting from coffee, and at least a third greater than that which follows the employment of the Ilex maté. When used in doses of thirty to forty grammes, an intense fever, accompanied with hallucinations and delirium, follows. Being among the first to call attention to the prompt, energetic, and almost poisonous action of the coca, I cannot but recommend its employment in diseases characterized by marked depression of the nervous and muscular system, and particularly in cholera."

Dr. Reis then goes on to state that he has used it during the recent epidemic, but adds that no severe cases came under his observation. In a few in which algid symptoms began to make their appearance, and the pulse was small and almost imperceptible, the use of the remedy was followed by apparently good results. It may be administered in the form of elixir, syrup, extract, infusion, masticatory, or may be smoked like tobacco. The experiments made in this country with the coca do not confirm the very sanguine opinions of Dr. Reis. The results have been contradictory. It is, however, a remedy worthy of further examination, since if half which has been told of it were true it would be very valuable in some nervous diseases.

Drs. N. Edsen Sheldon, of Glen's Falls, M. L. Lee, of Fulton, John G. Orton, of Binghamton, and Dr. H. C. May, of Corning, have been recently appointed Trustees of the New York State Institution for the Blind for the fourth, fifth, sixth, and seventh Judicial districts, respectively.

OVER-CROWDED EMIGRANT SHIPS.

"AN approaching pestilence," says some one, "unearths unsuspected filth." Probably had there been no fear of a choleraic visitation the secular press would have sounded no note of alarm regarding the condition of those whose means compel them to seek the miscalled comfort of a transatlantic trip in an emigrant ship.

We are informed, according to the statement of certain passengers on board the recently arrived steamship Queen, from Liverpool, that "the berths were only twenty inches wide, arranged in tiers, each tier forming a compartment about thirteen feet in length, ten in breadth, and eight in height," and that "twenty-four persons occupied one compartment."

With such a state of affairs, we are of course prepared to believe that "the foul smell in the compartments, especially during a gale of wind, which lasted the greater part of three days during the first week of the voyage, was intolerable. During the gale it was impossible for women and children to go on deck, and the stench in the steerage during that time was abominable."

"The most nourishing part of the food," says one who confesses to have traversed the Atlantic as a steerage-passenger out of eccentricity, "is served in the cabin." He complains of poor food, thirst, and the drinking of stagnant water, no washing, no undressing, filth in the hold of the ship, filth everywhere. We quote another paragraph in the protest, already cited: —"The dinner was fair, but in serving it out many often received none, owing to the insufficient number of stewards, and the small space allowed for passengers." In other words, during the scramble for food the strong were unmindful of the necessities of the weak, and the high order of talent required for the proper manipulation of large crowds was found wanting. To correct these very evils, Congress, by the Act March 3, 1855, provides "that no vessel shall have more than two tiers of berths; that the interval between the lowest part thereof and the deck beneath shall be not less than nine inches; that the berths shall not be less than six feet long and *two feet* wide, and no such berth shall be occupied by more than *one* passenger; that every apartment shall be *well* ventilated; provided with cabooses or cooking ranges;" that the apartments shall, "*at all times*," be kept "*in a clean, healthy state;*" that the decks and all parts of the apartments shall be so constructed that they "can be thoroughly cleansed;" and "a safe and *convenient* privy, or water-closet, for the exclusive use of every one hundred such passengers."

But the law-making principle being slightly in excess of the law-venerating element, particularly where inadequate penalties only add a piquancy to the violation of a well intended enactment, these waifs of humanity become the natural prey of venal corporations, that, in effect, even cut short their rations of untainted air. Let the owners of these liners be taught their responsibilities, as a cotemporary suggests, "by confiscation and forfeiture," instead of being *threatened* merely with a paltry fine of fifty dollars for carrying an illegal number of passengers, or of five dollars for every passenger in the event of the violated provision in the construction of the berths, etc., or of two hundred dollars for each failure to have the prescribed houses over the passage-ways, or the ventilators, or the cooking ranges, or the privies. We will admit that the statistical tables of Mr. Casserly, the Secretary of the Commissioners of Emigration, regarding the Atlantic steamship passenger-travel for the years 1864 and 1865, are most satisfactory exhibits; that one death to a thousand steerage-passengers, and only one to every 3,080 over eight years of age, are facts not quite as startling as the mortality ists of the Crimean war; we might even go a step further to prove that "Simon the Cellarer" *may* grow hoary-headed, but spare ourselves the task by propounding instead an enigma in which the cholera and the steerages of certain vessels can not well be omitted features. The power for mischief then being merely latent, not absent, we cannot but applaud the action of the present Congress, in pausing to devise means to secure the physical comfort of the immigrant, and through him to ward off, as far as human agency may, the attack of an impending pestilence.

WE regret to make the announcement that the building of the University Medical College of this city was completely destroyed by fire on the night of the 21st of May. The valuable museums of Professors Mott and Post have been entirely lost, together with the immense and costly laboratory of Professor Draper, and the rare collection of shells and minerals belonging to the Lyceum of Natural History. Notwithstanding, however, this appalling catastrophe, we are happy to be able to state that the Faculty have not allowed a single day's intermission in the spring course of lectures. The upper

portion of the Demilt Dispensary is now being temporarily used for a lecture-room. The friends of the College will be glad to learn that the institution is to be at once rebuilt, with many additions, and that the work will be carried on as rapidly as possible.

Reviews.

Successful Removal of the Uterus and both Ovaries, by Abdominal Section; the Tumor, Fibro-Cystic, weighing thirty-seven pounds. By Horatio Robinson Storer, M.D., of Boston. Philadelphia: Collins, 705 Jayne street. 1866.

This procedure, in the event of carcinoma, was merely proposed by Wrisberg in 1787, and again by Gutberlat in 1814; but it has been within a comparatively recent period that surgical interference to the extent indicated was attempted for the benign variety of tumor. Dr. Storer's case, as far as the attainable records go, is the sixth successful one. The details of this brilliant achievement, necessarily condensed, are as follows:—An unmarried lady, aged 47, whose catamenia had not yet ceased, in good health until within a period of five years prior to August, 1865, became conscious of the existence of an abdominal tumor, which soon began to steadily increase in size, until she became larger than a woman at the full term with twins. The diagnosis was rather by exclusion, and by no means certain. The operation, after the necessary preparations with a view of insuring as light a burden to the system as possible, was undertaken, with the assistance of Drs. Dix, Langmaid, and Tyng, on the 23d of September. Anæsthesia by ether was readily produced, the bladder emptied by catheter, and an incision of five inches made within the track of the right rectus muscle into the abdominal walls from just below the umbilicus downwards. The division of the several layers was carefully effected upon a director, and the very dark purple-hued tumor, which almost completely filled the abdominal cavity, exposed. To this adhered a very highly vascular omentum, the vessels of which were in part divided *en masse* by scissors, and the resulting hæmorrhage controlled by wire ligatures and torsion, while in a few of the instances resort was had to ligation before division. Upon the left of the tumor, and deep down, there were other extensive peritoneal adhesions, which were partly broken down and partly severed. The mass was now found continuous with another, also of large size and of very irregular outline, completely filling the cavity of the pelvis. For the sake of convenience in manipulation, a separation of the mass was effected by the écraseur, and the external opening enlarged by half an inch to allow extraction. The pelvic mass was found largely attached laterally, the morbid adhesions being chiefly to the left, very firm and vascular. Elevated sufficiently, although with great difficulty, to allow the passage of a clamp beneath to guard against opening the vaginal septum, the mass, as far as its broadened cervix was concerned, was, after much taxis, fully engaged, and excision accomplished by the écraseur. But owing to the firmness of the tissues and the cramped room, the jaws of the clamp were opened throughout nearly the whole of its extent, so that it fell from the stump the moment the tumor was cut away. Some six additional open vessels were treated by wire ligatures, several more twisted, and the operation practically completed. For the free blood oozing from the extensive surfaces of adhesion, alcohol and long exposure to the air were employed. In the interval, the blood in the cavity of the pelvis was finally sopped up by sponges, after repeated unsuccessful attempts for its removal by suction through a syringe and the use of a silver spoon. The incision was at length closed by the insertion of five wire sutures passing through the peritoneum, and the abdominal integument allowed to remain perfectly nude, and only protected from the bed-clothes by an appropriate wooden frame. During the operation, notwithstanding the flagging of the pulse, the ether was continuously administered to the extent of two pounds and a half.

The diet for the first day was nothing but ice; for a day or two subsequently, flour porridge with milk, or milk gruel, was repeatedly given. From this point greater latitude was allowed—twenty-four pounds of beef being consumed during the first month. From the onset, the pulse hardly exceeded one hundred. There was no nausea or vomiting; scarcely any jactitation was noticed, and but little pain or flatulence. No motion whatever of the body was permitted for ten days after the operation. Catheterism was employed until the third week to prevent effort on the patient's part, and on the fourth day a suppository of half a grain of morphia was introduced into the rectum for a like purpose.

An enema, however, on the sixteenth, and a natural stool on the eighteenth day, evacuated the bowels. The adhesion of the lips of the abdominal wound, which had not at all gaped from the beginning, was completed upon the third day; and the wires, untwisted on the tenth, were finally removed on the fourteenth. On the twenty-first day the patient sat up, on the twenty-eighth was out of bed, and on the thirty-seventh returned home from the hospital.

The first vaginal examination since the operation, which was made November 9th, discovered the cervix reduced to a mere nodule, and button-shaped. This loss of substance, the surgeon thinks, was due to the necessary stretching upwards of the pelvic mass, and consequent encroachment upon uterine tissue by the clamp and écraseur.

The tumor, now in the Medical College Museum, weighed in all thirty-seven pounds; the pelvic mass weighed eight, and the abdominal sixteen, after thirteen pints of fluid had been drawn from it. The character and relations of the mass were fully demonstrated before the Suffolk District Medical Society, on September 30th, by Professor I. B. S. Jackson, and Professor Calvin Lewis's examination leaves no doubt of the removal as indicated by the title.

The body of this interesting pamphlet is made up of the statistics and literature of the operation, interspersed with much ingenious reasoning and decidedly original views.

Eulogy on the late Valentine Mott, M.D., LL.D. By Alfred C. Post, M.D. Delivered before the New York Academy of Medicine, Nov. 27, 1865. New York: Baillière Brothers. 8vo., pp. 30.

Professor Post has, in the eulogy before us, given to the profession a very full and interesting history of the "Father of American Surgeons." He traces him from his cradle to his grave, and pictures the character of this great surgeon, not only as a professional man, but as a citizen and Christian. The narrative is truthfully told, and all the different points in the character of the distinguished subject of his sketch are well presented. The likeness of Dr. Mott which faces the title-page is well executed, and with the exception that it gives him a rather older look than belonged to him, is lifelike. The work is got up very tastefully, and is well printed. Every student and practitioner should become the possessor of this chaste memoir.

A Manual of Blowpipe Analysis and Determinative Mineralogy, by William Elderhorst, M.D., Professor of Chemistry in the Rensselaer Polytechnic Institute; Third Edition, revised and greatly enlarged. Philadelphia: T. Ellwood Zell, Nos. 17 and 19 South Sixth street, 1866.

Blowpipe Analysis is a department of science of very modern growth, when compared with the antiquity of many of the other appliances of heat. The art was founded and almost perfected by such men as Swab, Cronstedt, Von Engeström, Bergman, Gahn, and Berzelius. Very few advances have been made since the publication of Berzelius's Treatise, until within a very few years, when, in the hands of the German adepts, it accomplished quantitative results, while the ancient processes were extended and improved. Blowpipe analysis at the present time is, for practical purposes, a perfect science. It is of especial interest just now, as being, in connexion with certain discoveries in another department of the science, the germ of that most extraordinary result of modern chemistry—the "Spectral Analysis." The importance of a knowledge of the use of this instrument is now beginning to be universally recognised, furnishing as it does to the analyst a ready and swift result, to the experimenter an inexpensive trial, and to the mineralogist an unerring means of diagnosis, while the physician views with interest its applications in toxicology and the determination of calculi. The republication of this standard manual will doubtless be viewed with favor by student, teacher, and practitioner.

A manual on the blowpipe should be a very small affair that will readily slip into the coat-pocket, for it will be more frequently referred to in the field than in the work-room: we see at the first glance that our author has made this provision for the convenience of the student. The type too is large and distinct; but notwithstanding the small book and the large type, there is no improper excision of valuable matter, this point being gained by the adoption of a very condensed style —a great portion of the work being in the tabular form. This work is peculiarly adapted for the use of the beginner, and was "designed to serve as a text-book in the instruction in Blowpipe Analysis and Determinative Mineralogy, in the Rensselaer Polytechnic Institute." It has been endorsed by Professors Brush, Joy, Booth, Gibbs, Genth, Egleston, Chandler, and others.

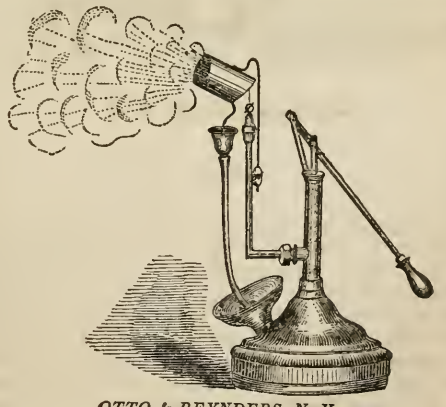
The first chapter treats of the auxiliary apparatus and reagents. The second gives the general routine of blowpipe analysis. A few engravings would not have been out of place in the two first chapters. In the third chapter we have special reactions for the detection of certain substances when in combination with others. The fourth chapter introduces us to the characteristics of the most important ores, their behavior before the blowpipe, and to solvents. This chapter "has been considerably enlarged by increasing the number of species, and by adding an Appendix containing the description and blowpipe reactions of the various kinds of fossil fuel." The fifth chapter is devoted to a systematic method for the discrimination of inorganic compounds. It is a slightly altered translation of the "*Division dichotomique pour reconnaître les minéraux*," from Laurent's "*Analyze au Chalumeau.*" The sixth chapter (not contained in the first edition) is on the discrimination of minerals by means of the blowpipe, aided by humid analysis. It is extracted from F. von Kobell's "*Tafeln zur Bestimmung der Mineralien.*" The book concludes with a series of three tables: Table I., on the behavior of the alkaline earths and the earths proper before the blowpipe; Table II., behavior of the metallic oxides before the blowpipe; Table III., the metallic oxides arranged with reference to the colors which they impart to the fluxes.

We notice that in the second section, page 21, which treats of the proper flame to be used, the sperm candle, the blowpipe lamp of Berzelius, and especially the common fluid lamp, is recommended; but no notice whatever is taken of that simple modification of Bunsen's burner now so extensively used. We can find no allusion to the use of the wedge containing a blue solution, or to the employment of colored glasses in the determination of a mixture of alkalies. Although these methods cannot compare with the refinements of prismatic observations, they are still of definite va'ue in the blowpipe analysis. Section eighty-nine, page 52, on the flame of lithia; and section ninety-seven, page 55, on the flame of potassa, are quite behind the age: the apparent elimination of the characteristic effect in these two cases by the presence of soda meets with no remedy in the text, and yet there were simple means of overcoming the difficulty before the introduction of the spectroscope.

New Instruments.

SPRAY-PRODUCING INSTRUMENTS.

So much interest has of late been awakened in reference to the treatment of disease by means of "pulverized fluids," that we have determined to present our readers with accounts of some of the most approved instruments that are now being used for that purpose The honor of originating this new method of treatment belongs to Sales Girons, who exhibited, in 1858, an apparatus for atomizing fluids before the Academy of Medicine, of Paris. Girons's instrument, by means of compressed air, forced medicated fluid through a tube with a fine aperture against a metal plate. By this procedure the stream of fluid was suddenly arrested, and was broken into a fine spray. The principle of the apparatus is exemplified in Fig. 1.



OTTO & REYNDERS, N. Y.

Fig. 1.

Dr. Bergson, of Berlin, next constructed an apparatus which was much simpler and more ingenious. It consisted of two glass tubes, each having a capillary aperture at one extremity. These capillary extremities were arranged at nearly right angles to each other, as

seen in Fig. 2. By blowing through the horizontal tube the current of air in the perpendicular tube is exhausted, the medicated fluid in the vessel rises to sup-

OTTO & REYNDERS, N. Y.

Fig. 2.

ply its place, and reaching the capillary orifice is instantly divided into spray.

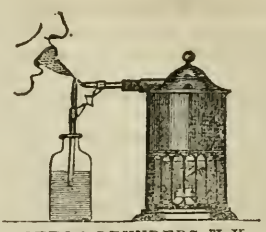
Dr. Siegle, of Stuttgart, has constructed an instrument by which Bergson's method of vaporizing is modified by using steam instead of air. The principle of this apparatus is shown in Fig. 3.

OTTO & REYNDERS, N. Y.

Fig. 3.

It consists of a copper boiler, A, fastened to a brass spirit-lamp, B, provided with a screw to regulate the amount of flame. To the tubular top of the boiler, the horizontal, the steam tube, C, terminating in a capillary orifice is attached. This is connected at nearly right angles with a perpendicular or exhausting tube, D, so that the upper extremity of the latter abuts against the lower half of the tubular extremity of the former. Into the top of the boiler is screwed a "thermo-barometer," or tube containing mercury, the lower end of which hangs in the space to be occupied by the steam; the upper end being exposed against a graduated scale. This scale serves to indicate the right temperature and pressure, for the production of the finest and most uniform spray. To insure perfect safety, a spring safety valve, F, is placed behind the steam tube, and readily permits the escape of superfluous steam.

Figure 4, is a simpler form of the same instrument.

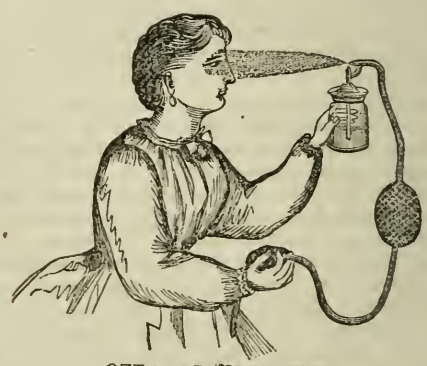


OTTO & REYNDERS, N. Y.

Fig. 4.

The advantages claimed for Siegle's apparatus are—First. That the spray produced is much finer and more uniform than that produced by any other instrument. Second. That the temperature of the spray can be raised to any elevation desired. Third. That the instrument when once set in motion requires no other attention than the most timid patient can give without trouble.

Dr. Andrew Clark, of London, has devised an apparatus (Fig. 5), which must be acknowledged to possess



OTTO & REYNDERS, N. Y.

Fig. 5.

great advantages in simplicity and extended application. It consists of an ounce bottle for holding the medicated fluid. Through the cork stopper of this, is passed the perpendicular limb of a Bergson's tube. To the horizontal limb is attached an india-rubber tube, terminating in two hollow balls placed at a short distance from each other. The one which is covered with network, is the air-reservoir, the other the air-pump. By alternately compressing and relaxing the end ball, the air-reservoir is distended as far as the network permits, when a continuous spray is produced.

This apparatus, as well as the others, can be used wherever it is necessary to apply a finely medicated spray to any surface. The patient in Fig. 5 is represented as applying the vapor to the eye.

Trichinosis.—This disease has not as yet appeared in France; but in order to be forearmed, a commission, consisting of Dr. Delpech, of Paris, and Professor Reynal, of the Veterinary School at Alfort—the first appointed by the Academy of Medicine, and the latter by the Minister of Agriculture—has been directed to proceed to Germany to study this disease in all its phases. On the way they will stop for a time in Belgium, where the disease has made its appearance at Huy.—*Boston Medical and Surgical Journal.*

Correspondence.

HYPODERMIC MEDICATION.

MEETING OF THE NORTHERN MEDICAL ASSOCIATION.

Philadelphia, April 15th, 1866.

SIR:—At the semi-monthly meeting of the Northern Association of this City, held last week, the following named gentlemen were elected delegates to the American Medical Association:—Drs. Slocum, Cohen, Richardson, Harlow, and Wittig.

Dr. Wittig presented in the name of an applicant for membership, a thesis entitled "*De Atrophia musculorum progressiva.*" This had been examined by several of the members, and is said to be a very valuable paper, and to be replete with authorities from the earliest records down to the present date. It will be translated and read before the Association at one of the meetings in May, when "Progressive Muscular Atrophy" will be the subject for discussion. I hope to be able to present you with an abstract of the paper for the columns of "THE RECORD."

The subject for discussion, at the meeting of the Northern Medical Association, held April 13th, was "Hypodermic Medication," and was opened by Dr. Robert Burns of Frankford, who stated that his intention was principally to open the subject for discussion, his own experience in the use of this method of therapeutics being as yet quite limited; although this experience, three or four representative cases of which he intended to narrate, was such as to corroborate the statements of many who, having give the subject mature consideration, had placed before the medical public a favorable record of their practical experience as to its utility. Dr. Burns's attention has been directed to this subject for several years, and he was particularly drawn to it from hearing a lecture on the subject by the late Dr. Mitchell, Professor of Materia Medica in the Jefferson Medical College of this City, upon which occasion Dr. Mitchell spoke much in favor of the subcutaneous injection of the salts of morphia in cases of Facial Neuralgia.

Since then articles have appeared from time to time in various of our periodicals laudatory of the practice. Within the past year the subject has been very handsomely brought before the public in a work by Antoine Rappauer, M D., Fellow of the Massachusetts Medical Society, and published in Boston in 1865. To this work he referred frequently during his remarks, considering it clearer and minuter in its details than any other of which he had knowledge. In May, 1860, Dr. Ruppauer published in the *Boston Medical and Surgical Journal* some notes entitled "*Researches upon the Treatment of Neuralgia by Subcutaneous Injection.*" In 1862 he read a paper before the Massachusetts Medical Society upon this subject, which was published in *Vol. X. No. II.* of their *Transactions.* "From that time to the present hypoder nic injection has had a more extensive trial among medical men than before." The practice has been used in other than purely neuralgic disease; by Mr. Hunter of London in *delirium tremens;* by Prof. Scanzoni in *puerperal peritonitis;* by M.M. Dupuy and Fournier in *tetanus;* by Mr. R. Ellis of Chelsea in *hysteria;* by Dr. J. H. Bennet of London in *uterine pains* and in *sea-sickness;* by Mr. J. Moore, of Bombay Medical Service, as well as by Dr. Classeaud of Smyrna, in *malarious fever;* by Dr. J. Mason Warren of Boston in *injuries of the nerves;* and by Dr. Von Graefe, who recently delivered a series of lectures on "*the employment of subcutaneous injections in Ophthalmic Surgery.*"

Dr. Ruppauer thus systematizes his work: 1st. The superiority of hypodermic injections as a therapeutic agent in the treatment of pain in many diseases. 2d. The diseases to which this treatment is applicable, and to which thus far it has been applied. 3d. Injections; their nature, extent, and limit. 4th. The instrument, operation, and point of injection. 5th. Cases treated in practice, and their results. 6th. Disadvantages arising from this treatment compared with its advantages.

Dr. Burns then went on to make some general remarks on the subject of pain, the dread sentinel of morbid action, whose approach is so dreaded by the patient, from which his physical nature shrinks, after alarming likewise friends and relatives by its frequence and violence. Happily the accumulated knowledge of the past and the accumulating discoveries rewarding scientific research, have provided us with agents great in power to subdue pain and relieve suffering. In the first rank of Anodynes we have Opium, with its numerous compounds; Chloroform, Sulphuric Ether, Nitrous Oxide Gas, Belladonna, Aconite, and many similar substances, through the instrumentality of which many a poor sufferer has been relieved of pain; and, if not cured, his tedious hours and sleepless nights have passed away in comfort. In order to produce this effect, various modes of administration have been practised; *by the alimentary canal, the respiratory organs, the dermoid surface,* and the *subcutaneous cellular membrane,* which latter method has excited a great deal of interest among medical men, for which there has been substantial reason.

In the first place, by injection into the cellular tissue, a medicinal agent comes into more intimate contact with the periphery of the nerves, and is much more quickly taken up by the absorbents into the circulation; hence in severe pain we have a means of prompt relief which we cannot obtain as effectually by the stomach, as in the latter case the medicine becomes mingled with the ingesta and stomachic secretions, by which, doubtless, it is often neutralized and slowly absorbed, to the disappointment of both physician and patient.

In many diseases also it is impossible to administer anything per os, as in convulsions, mania, delirium tremens, tetanus, hydrophobia, hysteria, tonsillitis; besides, many diseases affecting the nervous system are exceedingly obstinate, resisting the best directed efforts of the physician, and the usual remedies become inoperative in their effects, as in sciatica, ovaritis, uterine neuralgia, facial neuralgia, colica pictonum, intussusception, rachitis, and injuries attended with violent pain. In them, as well as in many others, much and decided relief can be obtained by the use of hypodermic injections; and not only in regard to the relief of pain alone is the method applicable, but bids fair to be resorted to to produce other effects on the organism in the treatment of morbid action. And, on the other hand, the method is likely to be attended with much danger in the hands of the rash or ignorant; for whom, however, it was never intended, and it is to be hoped that its use will never be extended beyond legitimate practice.

Dr. Burns then narrated the three following cases, selected from his practical experience, for the purpose of illustrating his grounds for considering favorably the utility of the method of medication:—

CASE I.—NEURALGIA; PRINCIPALLY OF HEAD AND STOMACH.—Mrs. Mary L——, a lady of wealth and refinement, whose physician Dr. Burns has been for a period of upwards of twenty years, during which time, and anteriorly, she has been a great sufferer from frequent attacks of *neuralgia,* confined generally to the head and stomach; but within a few years past the cardiac region seemed to become its favorite location. This condition often continued a length of time with excessive severity.

The whole catalogue of anodynes has at sundry times been used with but little benefit; cupping, blistering, and, in some congestive attacks, even venesection has been had recourse to; the tonic treatment has likewise been vigorously pursued in the administration of quinine, cinchonine, iron, bismuth, oxide and sulphate of zinc, &c. Antispasmodics have been given; valerian, with belladonna, and ammoniated valerian. Alteratives more especially directed to the condition of the digestive organs, as salines, bromines, mercurials, and even arsenic, which last could never be tolerated; all these, and many more which might be mentioned, were used time and again.

The last attack that this lady has experienced, began on the 16th of April, 1865, and was of more than usual severity. On the 5th, she was seized with fainting, severe pain in the hepatic region, with a congestive condition, and general impairment of the digestive functions. This state was relieved by venesection; blue mass, a blister over the liver, followed by quinine; and she was doing very well, although sleepless, and troubled with pains in various parts. About 10 o'clock on the night of the 15th, severe pain about the præcordium came on, which produced much suffering.

April 16.—No better. Ordered frictions with hot spirits and flannel to the extremities; bottles of hot water to the feet, sinapism to the spine; draught of brandy and water; and the following prescription: ℞. Acetatis morphiæ, grs. iv.; spts. ammon. aromat., f ʒ ij.; tr. aconit., gtt. xxxij.; chloroformi, f ʒ i.; aq. camphoræ, f ʒ ij.; Syrupi limonis f ʒ iss. M. ft. mistura. Of this, a teaspoonful was directed to be taken every half hour until three times; then every hour until easier. *At* 4.30 P.M., *Sunday*, she was very little better. The bowels had been opened, and five doses of the medicine prescribed had been taken. Having been so often disappointed with the usual remedies employed in this case, it was resolved to employ the hypodermic plan; therefore, at twenty minutes before five, the hypodermic syringe not being at hand, a puncture was made in the arm, near the insertion of the deltoid muscles, with a small bistoury; and with an Anel syringe for injecting the puncta lachrymalia, one-quarter grain of the acetate of morphia, dissolved in a drachm of water, was neatly injected, and the puncture was then closed by placing over it a small strip of adhesive plaster. The operation gave no pain, and was soon followed by a slight blush over the surrounding tissue for a considerable distance. *At* 6 *o'clock, same evening*, the patient was quiet, though she said she was no better, and was very anxious for immediate relief. Advised quietude and patience. *At* 10 *o'clock, same evening*, she was much easier, though there was still some pain. Still, on the whole, the patient felt much relieved. *April* 17.—9.30 A.M.—Had passed a comfortable night, with some sleep. Tongue much coated, but moist; some sense of coldness and indication of chill, though not decided. Gave directions accordingly. 9.30 P.M.—Has had a chill, but not much fever, and but little return of pain. *At her urgent request*, one-third grain of the acetate of morphia was introduced into the other arm, with but little loss. Ordered quin. sulph., in doses of two grains, to be taken before morning. *April* 18.—Has rested quietly through the night, and has taken the quinine. There is, at present, distress of stomach—inclination to vomit; the tongue is still coated. Ordered blue mass, grs. xv., with magnesia ʒ i.; and the effervescing neutral mixture of citrate of potash, made with fresh lemon-juice, to be given frequently in small doses. *April* 19.—Somewhat better; less sickness at stomach; bowels open; continues weak; tongue cleaning on edges. Ordered quin. sulph., grs. xxxij.; morph. sulph., grs. ij., elix. cinchonæ ʒ iv. made into a mixture. Dose, two teaspoonfuls every two hours until five or six doses are taken; afterwards, three or four times a day. *April* 20.—Doing favorably. *April* 21.—Appetite craving. *April* 23.—Better. Considerable debility. Still complains of soreness at the epigastric and hypochrondriac regions; bowels open; appetite improving; tongue cleaning. Has taken during the week, sixty-four grains of quinine, with the elixir of cinchona. Omit the quinine. Use the neutral effervescing draught; take animal food in small quantities. A little sweetbread with rice, which she desires, is permitted. *April* 25.—Introduced the third time one-third grain of acetate of morphia, upon the inner side of the arm, with very marked relief. Had a good night's rest, with much diminution of pain. The tongue is still coated. Ordered the following: ℞. Mass. hydrarg., grs. xxiv.; pulv. opii, grs. vj.; ext. taraxaci, q. s.; ft. pil, No. xxiv. Sig. One to be taken three times a day, with infus. pruni. virg. cort. The diet to be carefully guarded. Around one of the punctures there was a diffused inflammation, to which lead lotion was ordered. *April* 28.—For the fourth time, one-third grain acetate of morphia was introduced, this time on the mesial line of the left breast, where the pain so obstinately centred. *April* 29.—Has had a very comfortable night, and is to-day, upon the whole, much better. *May* 1.—Doing well and sitting up. Appetite is improving. Medicines to be continued. *May* 3.—Improving; sitting up; tongue cleaning; slight mercurialization; said she had a good deal of gastrodynia yesterday and last night. Discontinue the blue mass pills; continue the infusion of wild-cherry, and ordered ten-grain doses of the subnitrate of bismuth twice a day.

The inflamed puncture on the inner side of the arm continues troublesome and indurated. Directed the application of the lead lotion with opium. *May* 5.—Introduced one-third grain morph. acet. for the fifth time, selecting a spot between the scapula and vertebra. From this time forth, the patient continued steadily to convalesce, and regained her usual health, with less cardial distress than she experienced for years.

In this case the digestive organs were certainly at fault, with congestive intermittent, which materially aggravated the neuralgic diathesis, and from which she cannot be expected to be entirely exempt. By the use of hypodermic injections, however, she has derived much benefit, and places much confidence in them; and it is to be hoped that if there is a return of her much dreaded pain, there will be in them a speedy means of relief.

Case II.—Mania.—Jefferson C——, a young man to whom Dr. Burns was called on the night of May 26th, 1865. He was suddenly seized with mania, and became so unmanageable that it required four or five persons to restrain him from injuring himself or others. The administration of medicine by the mouth was impossible, and it even became necessary to bind him firmly to the bed. His loquacious noise was so great that it was imperative to produce quietude by some means. For this purpose one-third of a grain of acetate of morphia was injected into his arm on the first of June, which had the effect in a short time, and the night was passed in tolerable quietude. On the next morning he was more composed; but about 9 o'clock A.M. again became furious, when the operation was performed a second time. This was followed by similar results; and he continued under its tranquillizing effects until death relieved his earthly suffering. This was a very affecting case, and seemed to resemble low fever in a congestive form, affecting the meninges of the brain and medulla oblongata. The whole disease lasted but seven days, during three of which only Dr. B. was in attendance. In this

instance the hypodermic injection afforded much benefit by inducing quietude, relief of suffering to the patient, and satisfaction to his relatives and friends.

Case III.—Sciatica.—Charles Z——n, a blacksmith by occupation, and recently a volunteer in the Union army during the late rebellion. Dr. B. commenced his attendance on the 7th of March, 1866, he having then labored under his disease for the previous five weeks under the care of another physician. He is a German by birth, 35 years of age, of light complexion, and nervous temperament. On examination, he complained of an excruciating pain about the pelvis, groin, and entire right limb; that such was its severity, he had had no rest or sleep day or night for the previous five or six weeks. His entire limb manifested no unusual appearance, save apparent enlargement, with strong pulsation of the femoral artery, as it emerged under the crural arch, which at the moment favored the idea of an aneurismal condition. His pulse was good, skin natural, but tongue coated. He had been treated by blisters on the anterior of the thigh, and anodynes internally Dr. B. considered the case one of hepathic disorder, and neuralgia of the sciatic and lumbar nerves, communicating to the crural and cutaneous branches. Acting upon these views, he treated him with mercurial laxatives, Dover's powder with morphia at night, and quinine with iron. This course was pursued with constitutional benefit, and his condition was more comfortable. Still, the pain continued, and the anodyne at night was still urgently demanded. In order to break up this habit, and the more effectually to relieve him, Dr. B. resolved to employ hypodermic measures, and with the following result:

March 21.—Injected over the sciatic nerve. *March* 22.—Injected upon the anterior part of the thigh. These operations were not fully satisfactory from a defect in the syringe, yet marked relief was obtained; for, on *March* 23, he had three hours' sleep, the first refreshing rest he had for six weeks. *March* 24.—Injected by two punctures, one-third of a grain of acetate of morphia. *March* 25.—Quite easy, though the leg was weak and somewhat stiff. He was able to walk without support; had been down-stairs, and could sit upon the chair with comfort. *March* 30, and *April* 1.—He steadily improves, and has had no return of pain.

Dr. Burns also alluded to another case under treatment at the present time. A Mrs. McC——, who has been very sick for the past month with low fever and the most severe neuralgia of the pelvic viscera, especially the left ovarium and uterus, although both rectum and bladder were often affected, causing severe expulsive efforts. Under the use of general remedies she is improving, but great wakefulness and pain in the left groin and limb continue, with much violence at intervals.

March 31.—Injected ½ gr. acetate of morphia into the left thigh, a little below the inguinal region and inner side of the Sartorius muscle. *April* 1.—Has rested better than she had done for four weeks, and feels free from pain. *April* 2.—Pain returned last night, with pain also in the back, supposed to be premonitory of the menstrual period. Introduced ⅛ gr. of acetate of morphia into the inguinal region, where the pain is greatest. *April* 3.—Has slept all night, but this morning began to suffer exceedingly with pain in the back. Menstruation has taken place. A vaginal examination reveals the left ovarium very tender to the touch, and somewhat enlarged. The uterus is easy. Injected into the arm ⅛ gr. acetate of morphia. *April* 4.—Rested well; menstrual flow doing well. There is considerable debility. Ordered a table-spoonful of brandy every two hours until more invigorated, with 2 gr. doses of quinine every three hours; and in order further to control the pain of the ovary, applied over it a blister. *April* 5.—The blister has acted well, and pain is gone. Her face is covered with an exanthematous eruption of a rose color, which appeared before with several particles of *urticaria* on different parts of the extremities. *April* 6—She is this morning sitting up, having her hair cut off. She looks much better, and has no pain. *April* 7.—Last evening *urticaria* came out upon the surface of the body with most extreme irritation and excitement, causing her a night of great restlessness, with spasmodic action of the stomach and diaphragm. The eruption was red upon the face, but on the other parts of the surface pale. The itching was intolerable, and nervous scratching, accompanied with almost spasmodic action.

Ordered the following:—℞ Magnes. ust. ʒ ss.; spts. eth. nit. and tr. opii camph. *āā* ʒ ss.; ext. valerian, fluid ʒ j.; mucil. gum. acac. ʒ j.; sacch. alb. q. s. M. sig. A table-spoonful to be taken every three hours, and at bedtime one of the following powders:—℞ Sodæ bicarb. ʒ ss.; pulv. ipecac. comp. ʒ ss.; lupulin., grs. xij. M. Divide in pulv. vj. If one should not produce rest, to take another in two hours, and to have the surface sponged frequently with bran water.

April 8.—Much better. The magnesia mixture has operated very freely; had rest, but not much sleep; some perspiration; the urticaria is but little observable. Ordered the powders to be continued this evening.

The tormenting neuralgia appears to have passed away since the last hypodermic injection and blister. Query.—Had the morphia any agency in producing the urticaria? In this case Dr. B. presumed not, as it came out previously to the use of that medicine; and her tongue being coated, the condition of the digestive organs, with morbid secretions, seemed to be the cause.

April 9.—Much better. The eruption has disappeared. *April* 10, 11, and 12.—Continues better; appetite improving; tongue slowly cleaning; sometimes a little pain about the ovary, which is yet tender to the touch; the bowels are free. At the present time convalescence seems established.

In this case hypodermic medication certainly contributed materially to her recovery.

Thus Dr. Bourns felt justified, from the result of his own experience in this method of relieving pain, in being sanguine as to its advantages in a multitude of others; but he would not entertain the *one idea*, and have the syringe brought forth on every occasion; but when other means are used without relief, he deems it to be of valuable service. The use of it should be well guarded, and the medical remedies well studied and carefully selected.

The length of the remarks already made precluded attention to other uses of the method than already alluded to; and for the use of those who desired to pursue the subject, he would recommend the book of Dr. Rappauer.

In the discussion which followed, it seemed to be generally allowed that the advantages of hypodermic injection, as far as recognised by the members who had employed it, were principally palliative and temporary; the anodyne effects, when salts of morphia are employed, being more promptly exhibited than when administered by the mouth: but when the pain was so intense as to demand relief at all hazards, the production of relief in this way did not appear to compensate for the disadvantages produced by the puncture.

In army and hospital practice much benefit had accrued from subcutaneous injections of anodyne remedies in painful stumps, in procuring sleep after operations, and relief in the terrible sufferings at the terminal

extremities of wounded nerves; though in the majority of these cases the relief was temporary, requiring gradual increase in the strength of the injection to reproduce the effect.

None of the members taking part in the discussion had had personal experience in the subcutaneous injection of quinine in intermittent fever or articular rheumatism.

The benefit of relieving pain, even for a time, calling off the attention of the nervous centres from this symptom, and thus producing a general tranquillization favorable to the action of remedies administered as curative to the particular disease producing the suffering, was recognised; but even for this purpose it was thought the usual endermic method of sprinkling morphia over a previously blistered surface would generally fulfil all the indications that seemed to call for the endermic injection.

The space of this communication prevents the detailing of the arguments *pro* and *con.*; but the *résumé* given above is the impression left upon the mind of the writer by the remarks made, without reference to his own predilections, which are certainly favorable to the extended use of this hypodermic medication.

The relief of pain, however produced, is a great element of cure, and the prompter the relief, the sooner of course the beneficial effects of cessation of suffering. This can be no better exemplified than by alluding to cases of painful abscesses in young children, which must come under the observation of every practitioner. Whether a sequel of scarlatina, measles, or other affection, a felon, or otherwise produced, a physician will be called to prescribe for a painful swelling which has prevented the child from sleeping for several days perhaps. An abscess is recognised, the bistoury plunged in it; and if large, even before it is evacuated, the child will be dozing in the arms of its nurse.

Of course such cases are not parallel to these in which subcutaneous injection of anodynes is desirable; but the *pain* of the abscess is what prevents the child from sleeping, though the discharge of the pus is necessary to the cure; and so on in many affections, intense suffering prevents that *rest*, so invaluable as a therapeutic agent. As an adjuvant in the intelligent treatment of many painful affections, and other affections where remedies cannot be administered according to first principles, the hypodermic syringe should be given a prominent position in the armamentarium of the physician.

Yours truly,

C. J.

THE ALUMNI ASSOCIATION.

To the Editor of the Medical Record.

Sir:—You will allow me to notice an important omission in your account of the Eighth Annual Meeting of the Alumni Association of the College of Physicians and Surgeons. No mention is made of the elegant entertainment provided for the Alumni at the Ashland House (after the adjournment of the business meeting), by the exertions of Professor St. John of the Faculty, and of Dr. Jared Linsley of the Board of Trustees. I am unwilling that the labors of these gentlemen should be passed by without due acknowledgment, and have therefore great pleasure in making this announcement. The bountiful supply of Croton wine furnished by the liberality of Dr. R. J. Underhill (class of 1825) called forth a well merited compliment to the donor. The whole affair was a complete success, and demonstrated the advantage of holding our annual meetings under the "old roof tree," rather than in private houses.

One word more. The obituary notices of deceased alumni was a most interesting feature of the occasion, prepared with great labor by Dr. Ellsworth Eliot, Secretary. They should have received a special acknowledgment.

J. G. A.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK AND "ICONOCLASTIC TILTS."

To the Editor of the Medical Record.

Sir:—In the Record for May 1, a correspondent writes that he "almost failed to recognise *his* time-honored friend, the New York County Medical Society, under the name of the Medical Society of the County of New York." He asks, if "you can produce any authority for the violent change in nomenclature," and says, "the Society has certainly gained all its prestige under the terse, compact name of the New York County Medical, and not under the awkward, unmusical one recently sought to be given it." He then implores you "to desist from your iconoclastic tilts at authority, both written and traditional, and return with all possible speed to the good old usage," making thereby, in his opinion, a masterly retreat.

Having printed the proceedings of the Society as you received them, you are not responsible for the alleged outrage against authority and good taste, which has provoked an onslaught from your correspondent, calculated to alarm any one not familiar with dictionaries, even if the truth were on his side. In the present instance the reputation of your journal for accuracy will not be impaired.

In the first place *there is authority* for the name "The Medical Society of the County of New York." It is so written in the act of incorporation, and generally in its archives, and I am informed by one of its prominent members that the name of our sister society across the East River, is "The Medical Society of the County of Kings," which, in the opinion of your correspondent, is also a misnomer. Other authority, if called for, can be furnished.

Is the legal name of the Society in accordance with "good usage?" Is it "awkward" and "unmusical?" This point cannot be as authoritatively settled as the preceding, but it may be urged in its favor that it was given more than sixty years ago by its founders, among whom were Nicholas Romayne, Valentine Seaman, Samuel L. Mitchill, and David Hosack, and I can find nothing in their records to justify the belief that they or their successors, among whom may be named Mott and Francis, were dissatisfied with it. Under them and their name the Society did gain *some* prestige; and as they held high rank, not only as men of science, but of general culture, it may be excusable to trust to their judgment in regard to the name of an institution which they founded and cherished, rather than to the assertion of an anonymous dogmatist.

A few words in regard to the "iconoclastic tilt.' Should any one succeed in establishing the applicability of this high-sounding phrase to the question raised, perhaps the process which results in conviction will be sent to you for publication.

Is there any reason for a retreat? Were your correspondent your military superior, I suppose that his advice would be tantamount to an imperative order; but as you do not sustain that relation to him, I hope you will continue to abide by the advice of Davy Crockett, "Be sure you're right, then go ahead," to which also you may safely commend all your corres-

pondents. Then they will not be misled by terms loosely and inaccurately applied.

ELLSWORTH ELIOT, M.D.,
Record. Sec. of "The Med. Society of the County of New York."

Medical News.

THE LATE PROF. JOSEPH M. SMITH—IN MEMORIAM.—At a quarterly meeting of the Trustees of the College of Physicians and Surgeons in the City of New York, held on the 8th ult., the following resolutions, relative to the decease of Prof. Joseph M. Smith, were unanimously adopted:

Whereas, In the dispensation of an all-wise Providence, Joseph M. Smith, M.D., late a member of the Faculty of this College, was removed by death on the 22d April ult.;

Therefore Resolved, That this Board, while they deeply deplore the loss of such a Professor of such distinguished excellence and ability, cannot forbear expressing their gratitude to God, that in his mercy, the College was permitted to enjoy for so many years his valuable and uninterrupted services.

Resolved, That the uniform ability and fidelity with which for nearly forty years Doctor Smith performed the functions of Professor, first of Theory and Practice of Medicine and Clinical Medicine, and subsequently of Materia Medica and Clinical Medicine, have contributed in an eminent degree to the steadily advancing reputation and prosperity of the College.

Resolved, That not only the professional eminence attained and so long enjoyed by Dr. Smith, commanded our respect and confidence, as it did that of the medical profession and community at large, but his amiable and dignified manners and christian excellence of character won our affection and personal attachment.

Resolved, That a copy of these resolutions be entered on the minutes and communicated by the Registrar to the family of the deceased, with the assurance of our heartfelt sympathy.

EDWARD DELAFIELD, M.D., President.
GURDON BUCK, M.D., Registrar.

CHOLERA AND QUARANTINE.—At a meeting of distinguished medical men from all sections of the Union (numbering between sixty and seventy), who met at Baltimore on the 4th ult., at the rooms of the Medico-Chirurgical Society, at 8 P.M., the following proceedings took place:

Dr. Charles A. Lee, of New York, was called to the chair, and T. E. Bond, of Maryland, appointed Secretary. On motion of Dr. T. Donaldson, of Maryland, the following memorial to Congress was adopted:

To the Honorable the Senate and House of Representatives of the United States:

The undersigned, being deeply impressed with the necessity of prompt and efficient measures for protecting the community against the approach of Asiatic cholera, and believing that the scientific investigations since 1832 have demonstrated the portability and communicability of the disease, petition your Honorable Body to adopt a uniform and efficient system of quarantine at every port, on some such system as recommended by Dr. Marsden, of Quebec, whose plan we beg leave respectfully to submit.

On motion, a committee, consisting of Dr. Charles A. Lee, of New York; Dr. Edw. Warner, of Baltimore; Dr. Sayre, of New York; Dr. J. L. Atlee, of Penn.; and Dr. N. Pinkney, U.S.N., were appointed to present this memorial to Congress.

THE NATIONAL STEAM NAVIGATION COMPANY have decided to stop German emigration by their vessels, and the British government has ordered a strict examination of all German emigrants before their admission to England.

GUADALOUPE.—The bark Helena Morton, from Guadaloupe, an infected port, with a clean bill of health and nineteen days out, has had permission, after a brief quarantine, to come to port.

"SUGAR PREVENTING GENERATION.—Mr. Tanner, Professor of Rural Economy in Queen's College, England, is inclined to believe that by the use of sugar as food, any animal may be rendered incompetent to propagate its species. He was led to this opinion by observing that some stock which had been fattened on molasses, mixed with dry food, were rendered barren, and that heifers fed in the same way escaped the periodical excitement of the breeding season. It was doubtful whether the power of reproduction was ever regained. The effect is attributed to a fatty augmentation of the ovaries, from which recovery might be difficult."—*Pacific Medical Journal*

Ourselves as Others see Us.—Under the title "State of the Profession of Medicine in America," a writer from New York, in the "*Wiener Medizinische Presse*," gives quite a graphic picture of ourselves. We condense and quote:

"The practice of medicine is free in the widest sense of the word. The State scarcely troubles itself about the physician. No law exists which requires a diploma as a prerequisite to practice. Any one in America may give himself the title of 'Doctor.' * * * * Under such circumstances we need not be surprised, if an American celebrates its triumphs, which are often mournful ones, since there physicians spring from the ground like mushrooms. A nurse, without further ado, opens an office, and in the same way a barber. But many others whose pursuits have had no tendency to medical knowledge, who have been merchants, writers, clergymen, etc., take up the doctor's handicraft. Some learn the profession as the cobbler does his; that is, they stay for a while with a physician of long practice. Still, the greater number of those who enter the profession attend the medical schools, of which there are a great number in America. Not a few foreigners also figure here as physicians. This number is composed partly of regular graduates, and partly of those who have failed in their examination, or who have never come up for it. * * * * Wherever a great number of physicians find themselves together, there a medical college is formed, which is recognised by the State.

"The course of instruction in these schools is generally very defective. No preparatory studies are pursued. (!) The course of instruction lasts in these schools generally sixteen weeks. * * * * We may be certainly surprised if in spite of this, in America, not unfrequently physicians are found that are not only excellent practitioners, but who are fully conversant with the literature of the profession, even the foreign. With us Germans, many a one folds his hands, after the examination, and draws throughout his life from what he has learned at the schools. This is less apt to occur with the Yankee; a part of whose character is to pursue with ardor an avocation which he has once undertaken, and always to bear any kind of trouble and labor (even if he become rich), which his profession may bring to him. A good knowledge of Materia Medica and Therapeutics (arzneimittellehre) is most prominent among American physicians; but unfortunately, there is a great want of knowledge of pathological anatomy. Months pass before even a good and busy practitioner makes a post-mortem, and as to the others of the quack order, they never saw one; but it is all the same as if they did."

Changes and Appointments in the Metropolitan Health Board.—Dr. Samuel R. Percy has been appointed a special inspector, with title of clerk; his duties are to have reference to the milk offered for sale. Dr. George W. Bayles and Dr. J. Lawrence Hicks have been appointed sanitary inspectors; the latter for the town of Flushing, L. I.

Danger of Hypodermic Injections.—The London *Medical Times and Gazette* describes an accident which lately happened to Prof. Nassbaum, of Munich. Suffering from neuralgia he had injected morphia under his own skin more than 2,000 times, sometimes to the extent of five grains in twenty-five hours. On one occasion lately he injected two grains acetate of morphia dissolved in fifteen minims of water into a subcutaneous vein, and for two hours his life was in imminent peril. We do not see clearly why the result should be serious, unless a small portion of air was injected. The Professor must have gone to work very carelessly, either to do this, or to penetrate a vein. Nothing is more easy than to avoid both accidents. After all, we may excuse the one mistake in 2000 operations.—*Pacific Medical and Surgical Journal and Press.*

"Diabetes Cured by a Seton.—In the French Academy of Science a case was narrated of a man, aged thirty-eight, much wasted with diabetes, who had been treated unsuccessfully for eight months with the usual remedies, and who had a large seton put in his neck at the end of that time. The sugar in the urine diminished as the suppuration continued, and in six months entirely disappeared. The man returned to his work, and for a year had remained perfectly well. With what indication the seton was used, or how it acted, is not explained. Besides, it is a good rule not to accept the truth of such statements without good evidence."—*Pacific Medical Journal.*

Vaccination in Cuba.—According to official returns, 8,696 vaccinations were made in this island during the last six months of 1865. Of these there were in Havana only 1,210, of which 741 were whites, and 467 colored. The total number of whites vaccinated on the island, was 4,697 during those six months.

The Climate of Africa.—Doctor Livingstone recently stated in a lecture, that no less than forty missionaries succumbed to the deadly effects of the climate of Africa before a single conversion took place.

A New Material for Sculptors.—M. Henri St. Claire Deville lately communicated to the Academy of Sciences of Paris, the fact that magnesia obtained by calcination from chloride of magnesium will, when exposed to the action of water for some months, acquire considerable consistency, and become hard enough to cut like marble. A lamina of this magnesia of moderate thickness is translucid like alabaster. With this substance, M. Deville has been enabled to take casts as if with plaster of Paris, only the former sets under water. A mixture of chalk and magnesia in powder, made up into a paste with water, is good for moulding, and will become exceedingly hard under water.

Report of an English Burial Board.—The Liverpool (Eng.) Burial Board has adopted a report in favor of abolishing interments on Sundays, on the grounds that the moral effect of such funerals is bad, that they were conducted with less decorum than on other days, and were the direct cause of contagion and death.

Appointments in the College of Physicians and Surgeons, N. Y.—Dr. Freeman J. Bumstead has been appointed Professor of Materia Medica and Clinical Medicine to fill the vacancy occasioned by the death of Prof. Joseph M. Smith. Dr. Henry B. Sands has been promoted Professor adjunct of Anatomy, and Dr. Erskine Mason elected Demonstrator of Anatomy.

Surgeon E. S. Bogart has been detached from Naval Hospital at New York, and is waiting orders.

Original Communications.

INTUSSUSCEPTION OF THE SMALL INTESTINES IN INFANCY.

By J. LEWIS SMITH, M. D.

CURATOR OF THE NURSERY AND CHILD'S HOSPITAL, PHYSICIAN TO THE PROTESTANT EPISCOPAL ORPHAN ASYLUM, PHYSICIAN TO THE CHARITY HOSPITAL.

Simple intussusception—or, as Rilliet and Barthez express it, intussusception without symptoms—is common in the infant, and its seat is always the small intestines. It is reduced by slight traction, and it is attended by no anatomical alteration, except the displacement. The invaginated mass is found in the upper part of the ileum, or in the jejunum, and usually more than one is present in the same patient. I have counted ten at variable distances along the jejunum and the contiguous part of the ileum. Simple intussusception is supposed by many to occur at the moment of death. Not being attended by symptoms, it is a matter of little pathological and no therapeutic interest.

Intussusception with symptoms, in infancy—or as writers variously term it, making no account of the simple form—intussusception, invagination, or volvulus, usually occurs in the large intestines. Some of the most eminent authorities in infantile pathology say that it always does. The purpose of this paper is to show that intussusception, irreducible and even fatal, may occur in the small intestines during infancy, though less frequently than in childhood or adult life. This is indeed admitted by Bouchut, who says (Diseases of Children): "M. Rilliet states in a recent treatise, that in infancy the intestinal invagination is always accomplished at the expense of the large intestine, and that there is never invagination of the small intestine. I have observed the small intestine invaginated in the adjacent inferior part. Taylor has reported a case of this kind in a child twenty months old, who died after an attack of acute peritonitis. M. Marage has seen another case in a child thirteen months old, who recovered after having voided the invaginated portion, furnished with two of these diverticula, so frequent in the small intestine of the fœtus."

Objection may be raised to the cases cited by Bouchut. From all that appears, the one reported by M. Marage may have been, and probably was, an example of the common form of intussusception, that of the ileum into the colon, the internal or iliac portion being expelled, while the external portion of the colon formed new attachments and remained. Mr. Taylor's case was probably included in the statistics of a paper published by myself in the "American Journal of Medical Science," in 1862, as one of the cases in the table contained in that paper was an infant of twenty months, observed and treated by a Mr. Taylor. In this patient, the invagination was really of the ileum into the colon, although a small portion of the ileum next to the valve had not been inverted, and it therefore constituted a part of the exterior of the mass.

The following cases, I believe, are genuine examples of irreducible intussusception of the small intestines in infancy. They were observed and in part treated by myself, the first in the family of a physician of this city, the second in the New York Infant Asylum, and the third in the children's department of the Charity Hospital. Probably at first the intussusception in these cases was of the simple variety, but continuing, and the displacement increasing, the return of the intestine soon became impossible.

Case I.—This patient's health had been uniformly good, and nothing unusual was observed in its condition till the age of four and a half months, when it became restless, as if in almost constant pain, with occasional exacerbations. Castor oil was prescribed, which operated freely, and then the following mixture:

℞. Magnes. calcinat. ʒi.; Tinct. opii. camphor. ʒii; tinct. asafœt. ʒ ss.; aq. anisi ℥ i. M. *Dose*, ten to twenty drops, repeated according to the pain.

These remedies failed to give relief, as did also chloroform, given in doses of two drops. After two or three days, another set of symptoms arose, those characteristic of pneumonia, namely, hurried respiration, accelerated pulse, short suppressed cough, and expiratory moan. He was treated with the oil-silk jacket, moderate counter-irritation, and an expectorant mixture containing carbonate of ammonia; and in a few days the pulmonary disease was evidently subsiding, but the pain in the abdomen, with occasional exacerbations, continued. His countenance was pallid, and bore an expression of suffering. There was no distension or tenderness of abdomen, and no abdominal tumor. He took little nutriment, and seldom vomited. In the last part of his sickness the dejections were scanty, and the last three days they consisted mainly of mucus and a little blood. The pain seemed to be growing less, when he was seized with convulsions, and died the same day, precisely two weeks from the commencement of his sickness.

Sec. Cadav.—Head not examined; body slightly emaciated; mucous membrane of trachea and bronchial tubes vascular; posterior portion of the lower lobe of each lung solid, of a greater specific gravity than water, and not susceptible of inflation; it was in the second stage of pneumonia.

Stomach, duodenum, jejunum, healthy. In the upper part of the ileum was an intussusception two-thirds of an inch long, presenting no trace of inflammation, either within or around it, and its vascularity not notably increased. Above the intussusception, the intestine was empty; below it, and chiefly in the small intestine, was a dark substance, evidently blood, and giving in a few hours the offensive odor of decaying animal matter. There was a passage through the intussusception, at least two or three lines in diameter, as shown by a probe.

The intussusception sustained the weight of sixteen inches of the intestine, and it would apparently have sustained considerably more. The remaining organs were healthy.

Case II.—F. S., a female infant, four months old, was treated at the New York Infant Asylum in June and July, 1865, for entero-colitis, the usual infantile epidemic of the summer season. The following records show the state of the bowels immediately before her death.

June 24th—Has five or six stools daily; *June 30th*—Two stools in twenty-four hours; *July 1st*—Had two stools since the last record; no vomiting; *July 3d*—Four dejections in twenty-four hours; *July 4th*—The diarrhœa continues as before; dejections about four daily. On the 6th of July she died.

Her pulse during the time these records were taken, generally numbered about 128 per minute. She was much emaciated at the time of her death. The medicines employed were mainly alkalies and astringents.

Sec. Cadav.—Parietal bones united, serous effusion lying over the convolutions of the brain, under the arachnoid; occipital bone depressed; commencing at a point about two feet below the stomach were four intussusceptions, two or three inches from each other. The invaginated masses were from one to one and a

half inches in length, and three of them were found to be very vascular in their interior. Above, between, and immediately below the intussusceptions, the intestine was healthy. One of the invaginations was tested by weight, and was found to sustain one and a half feet of intestine, and would have sustained more. Water poured above these intussusceptions, escaped through them very slowly. No fibrinous exudation; descending colon vascular and thickened, and solitary glands enlarged.

Case III.—M. M., female, aged four and a half months, was admitted into Charity Hospital, in good condition, on the 6th of April, 1866. It was nursed by its mother till the time of its admission, after which it was bottle-fed. Nothing unusual was observed in its condition until April 12th, when it began to vomit frequently. The bowels were open, but the dejections were small, and not frequent. On the 13th, he vomiting continued, and the records state that there was no diarrhœa. She was becoming emaciated; her countenance was pallid, and it indicated grave disease. On the 14th, the stools were scanty, and the vomiting continued at short intervals. She was sinking rapidly. On the 15th there was much prostration, and the vomiting had nearly ceased. The substance vomited had a dark color. The stools, which were scanty and infrequent, seemed to be chiefly fœcal, containing no blood, and little if any mucus. On the 15th convulsions occurred, attended by an upward direction of the eyes, and the following night death ensued.

Autopsy.—In the haste of the examination, the cranium, unfortunately, was not opened. The lungs seemed healthy, with the exception of slight sub-pleural emphysema; the stomach and upper part of small intestines were healthy, with the exception of a few vascular patches in the latter. In the ileum, perhaps two feet above the ileo-cæcal valve, was an intussusception, two and a half inches in length, firm on pressure, of a reddish livid color, about one inch in diameter, whereas the intestine above and below measured about half an inch. There was no plastic exudation, or other evidence of inflammation. Below this intussusception the intestine, examined through its coats, presented also a livid appearance, as if containing blood. It contained fœcal matter and mucus apparently tinged with blood; but no blood discs were found in the examination by the microscope. The invaginated mass was a little larger above than below, and it had a crescentic shape, the concave side corresponding with the attachment of the mesentery.

Thirteen inches below this intussusception was a second one, in which the lower part of the ileum, the ascending and transverse divisions of the colon, were engaged. The mass occupied the site of the transverse colon: it was three inches long, by an inch and one-eighth in diameter, and was also crescentic. Its color was not so livid as that of the first intussusception, and it presented no evidence of inflammation. Below it the intestine was nearly empty, and it contained no blood. The mucous membrane of the descending colon, and the rectum, were slightly injected, but otherwise seemed healthy. The intestine was removed entire from the stomach to the anus; and it was suspended first from one and then the other extremity without any appreciable effect on either extremity. An attempt was made to force water, by a syringe, through the upper intussusception, but the water escaped just above the mass; I am not certain that any penetrated it.

The irreducible character of the intussusception in the above cases, was shown by the fact that they sustained weights which doubtless produced much greater traction than that exerted by the intestine in its normal action.

That the displacement existed prior to the moment of death, was shown by the symptoms, and by the congestion of the incarcerated portions, which in one, if not two of the cases, was so great that the capillaries were ruptured.

TEMPORARY PARALYSIS OF THE VOCAL CHORDS AND APHONIA,

THE PARALYSIS OVERCOME BY DIRECT STIMULATION IN A SINGLE OPERATION, AND THE VOICE RESTORED BY LARYNGEAL AND VOCAL GYMNASTICS AT THE SAME SITTING.

By J. SOLIS COHEN, M.D.,
OF PHILADELPHIA.

On the 6th of March, 1866, Mary Ann C—r, of Bristol, Pa., æt. 40, married, childless, was brought by her husband to my office, having been sent by my friend S—, to be treated for a complete aphonia that had existed for several months.

Mrs. C— is a sparely built woman, of good height, of light complexion. She has been married twenty-one years, without issue; has always been "regular;" has always been in good health, and led a pretty active life. Her appearance indicated a tuberculous diathesis, but physical exploration and hereditary history gave no evidence of this condition.

She has unaccountably lost her voice on four or five occasions, the first one occurring about ten years ago. Her voice would return suddenly after a day or two; on one occasion her voice had left her for ten days. More than a year ago her voice suddenly left her, and did not return, despite local (probanging) as well as general treatment, for several months, when it suddenly returned. These attacks of aphonia occurred during the winter and early spring months. In February of 1864 she lost her voice, and remained in this condition for seven months, when she recovered it just previous to an attack of typhoid fever. On none of these occasions had she been exposed to sudden or excessive change of temperature, diet, or habits of life.

The present condition occurred at Christmas. December 24, 1865, was a cold night. She went to bed as well as usual, and when she awoke in the morning she could not utter a sound; in which condition she had since remained.

The aphonia was complete; by no effort I could direct her to make, could a sound be produced. The voice was altogether oral, and in a very low and feeble whisper. Laryngoscopic examination revealed no organic lesion, but the arytenoid cartilages moved but slightly, and that sluggishly; and the glottis remained patulous. The condition appeared to be an idiopathic paralysis of the thyro-arytenoid and other muscles moving the vocal chords.

I told the patient that in all probability her voice could be restored, by passing a current of galvanism through the vocal chords, and to suit her convenience, appointed March 13 for the operation; and directed her meanwhile to practise before a looking-glass, extending her tongue and keeping the base hollowed, and at the same time touching the uvula and pharynx with the handle of her tooth-brush.

At the day appointed she presented herself, and so well had she followed my instructions, that I was able with my probe to touch the vocal chords at the first attempt. Feeling confident of being able to restore the natural condition by a few applications of galvanism, I felt no hesitation in performing an experiment to see

whether other stimulation would not be as effectual; so, without advising her of my change of plan, I dipped a laryngeal brush in tincture of iodine, and inserting it between the lips of the glottis, swept from behind forwards the whole inferior face of the vocal chords. As the instrument and mirror were withdrawn, I saw the tremulous motion of the vocal chords, though reflex action supervened before I could see how closely they approached.

After my patient recovered from the suffocative effect of the application, I again introduced the mirror, and was pleased to discover during respiration a proper movement of the arytenoids.

Directing a vocal effort, the anterior extremities of the chords were seen to approximate, though they did not touch their whole length. The paralysis being overcome, I *insisted* on the patient making a sound, but for a long time without effect. Eventually a short, sharp note, like the sound of a mouse, was produced; and from this I worked, pursuing the gymnastic efforts recommended by Bruns. I first selected the sounds easiest to make, those earliest employed by the infant, as *ah, ah, ah*, making the patient repeat after me. Finally, she was able to make this sound feebly. Then I began with *eh, eh, eh*, with similar result. The sound of the vowel *o* was the most difficult; next that of *u*, next *i;* the sound of *e* and *a* about alike. As soon as my patient could make the sound of *a, e, ah*, I began adding consonants, thus *mam, mam, mam*, as a child does. Notwithstanding she could say *ah* very well, and make the *m* sound with the lips closed, she could not make the syllable except in a whisper. Then I made her hiss between the closed teeth, and during the hiss rapidly make an easy vowel sound, she following all the time the sounds as I made them myself. Thus, *s* prolonged, quickly followed by *a* or *e*, making *say, see*, and so on. As she would make one sound, I would continue it, repeating it gradually more and more rapidly, until she could make it by her own effort. Even when she had succeeded in making the easier vowel sounds, on attempting to utter a syllable, it would come in a whisper.

Suffice it to say, that by continuing this exercise, gradually enlarging the difficulty and number of syllabic sounds, at the end of two hours she was able to converse audibly; but her voice had not its natural strength, though it was of proper pitch.

Her voice daily improved, and on the following Sunday, five days after her gymnastics, she sang in church with a great deal of gusto.

A full month having elapsed without a return of the aphonia, I feel justified in placing this case on record, and recommending the example to be followed in similar cases.

I do not think that the *iodine* was of any benefit, and I attribute the overpowering of the paralysis to the stimulating effect of the direct application of the alcohol of the tincture.

At a future date I propose to present a tabulated statement of similar cases, in which the paralysis having been overcome by direct application of galvanic or other stimulus, the voice has been restored after a few gymnastic exercises.

I shall also have something to say about the therapeutic effect on functional aphonia of vital induction or cerebral energy on the part of the operator.

Produce of Mercury.—The produce of the New Almaden (Spain) mines for the last ten years has averaged about two thousand five hundred flasks, of seventy-six and one-half pounds each, of mercury per month.

SINGULAR WOUND OF TONGUE—OPERATION.

By HAZARD A. POTTER, M.D.,

GENEVA, NEW YORK.

Col. E. Sherrill, of the 126th Regiment New York Volunteers, September 14, 1862, at the battle of Harper's Ferry, received a wound in the face from a minié ball, which entered the left cheek, immediately anterior to the lower border of the masseter muscle, and passed out at a corresponding point on the opposite side.

I was called to see Col. Sherrill immediately after his arrival at his home in this place—about one week after the injury—and found him in an extremely feeble condition. There had been almost constant hæmorrhage from the mouth since the wound was received, and it was evident he could live but a short time unless it was immediately controlled. The buccal cavities were distended with coagula and speech was almost entirely prevented. In order to make the examination thorough and find the cause of hæmorrhage, and to control the same, the patient was placed in a sitting position to prevent the blood interfering with respiration, and chloroform administered to full anæsthesia. I was assisted in the operation by Drs. Dox, Stone, and Gilbert. Having removed the coagula, I found that all the teeth of the lower jaw, except two molars on each side, and some of the upper jaw, had been knocked out. Failing to discover any hæmorrhage from the gums or dental arteries, the examination was continued, and a small hole finally detected on the under and posterior surface of the tongue, from which a constant oozing of blood was apparent. Upon introducing a probe, a hard substance was encountered about two inches from the external orifice. Owing, however, to extensive granulations, it was found impossible to extract the body through the opening. The tongue was thereupon forcibly extended and an incision one inch in length made on the dorsum of the tongue, directly down upon the foreign body, which was withdrawn and found to be a large molar tooth. The ranine artery of the left side and two small branches were secured with silk ligature, the lips of incision closely approximated and the operation was concluded, and the patient rapidly recovered, and in a short time returned to the army. He served with eminent distinction in the Army of the Potomac, and fell mortally wounded while bravely leading his brigade at the memorable battle of Gettysburg.

Effects of Civilization upon the Floral Kingdom.—The Flora of the State of Pennsylvania is found to have undergone remarkable changes, plants that were formerly rare being now quite abundant. This effect is attributed to the spread of railways, and the change is so marked that some botanists think the "foreign" Flora will supplant the native. The valley of the Susquehanna has already been taken possession of by the invaders.

Action of Hydrofluoric Acid upon Glass.—By carefully attacking glass with hydrofluoric acid, microscopic crystals are developed, which proves that we are not yet acquainted with the true composition of this substance. The crystals vary with different glasses.

A New Mineral.—Professor Knop, of Leipsig, while searching for crystallized specimens of crysolite, has found a new mineral, to which, from its appearance, he has given the name pachnolite, from a Greek word, meaning "frost."

CLINICAL LECTURES
UPON
DISEASES OF THE GENITO-URINARY ORGANS,

DELIVERED AT THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF NEW YORK,

By W. H. VAN BUREN, M.D.,
PROF. OF ANATOMY, ETC.

Lecture I.

On Traumatic Stricture.

February 6, 1866.

Gentlemen—We have before us a boy of seventeen, who was subjected to the operation known as "perineal section" for an impassable traumatic stricture of the urethra, at St. Vincent's Hospital, on the 16th of December last, by Dr. Gouley. He has recovered happily from the operation and is cured, as far as a stricture of this sort is curable, by the art of the surgeon. He has been taught to introduce, for himself, a full-sized steel sound (No. 14) into the bladder, and I wish you to witness the facility with which he uses the instrument, and to impress upon you the clinical fact that this is the sole condition by which a cure can be rendered permanent in stricture which has resulted from mechanical injury of the urethra.

You will remember, also, a patient who applied for relief at our last cliuique; he was passing his water with great difficulty, drop by drop, with great straining, and constantly recurring desire to empty his bladder. He was a fine, honest, healthy-looking mechanic, and told us he had fallen astride a beam and bruised his perinæum some six weeks before, whilst at his work as a carpenter. It was ascertained that a full-sized sound was arrested by an impassable obstruction near the triangular ligament; and the point of a fine conical bougie was with difficulty engaged in a hard, resisting, sensitive stricture, through which it could not be passed.

I saw this patient on the same evening with Dr. Gouley, and after a careful examination of his case, I advised that he also should submit to the operation of perineal section. The grounds for these opinions were, first, that the sensitiveness and rigidity of his stricture, in view of the intractable character, established by experience, of traumatic strictures, forbade any reasonable hope of success from the use of dilation; second, that his urethra, behind the stricture, his bladder, ureters, and kidneys, were suffering serious injury from the impediment to the escape of the urine, and that he was in momentary danger of complete retention.

The operation was done by Dr. Gouley on the day but one afterwards, by a process which I will describe to you in detail, and the patient is to-day (the fourth from the operation), passing his water freely by the urethra and through the perineal wound, which is already commencing to heal, and he promises to make as fair a recovery as in the case before you.

The coincidence of these two interesting and important cases furnishes me with a text for some remarks in regard to the proper treatment of traumatic strictures, a subject in which I have taken great interest, and concerning which you will find but scanty and unsatisfactory information in the standard surgical authorities.

Let me promise that over 90 per cent. of the cases of stricture to which the term *traumatic* is properly applied, are the result of contusions of the perinæum, a region of the body which you would suppose was sufficiently protected by its position from external violence; and yet I speak advisedly in asserting that stricture from this cause is more frequent than is generally supposed, for I have collected, without much difficulty, trustworthy details of more than a hundred cases of this nature.

The mode in which the accident most generally occurs is by a fall across a beam, a log, or a fence-rail, or by falling with one leg through a hatchway, a trap-door, or an imperfectly-fastened coal-hole in the sidewalk. A large proportion of the sufferers are boys or young men, and the existence of a bad stricture in early life affords good ground for suspicion that it has resulted from injury, rather than from the more common cause of this disease—gonorrhœal inflammation.

A glance at the anatomical relations of the urethral canal to the pubic arch as it passes through the triangular ligament, in emerging from the pelvis, will explain the frequency of this variety of stricture. The subpubic ligament which forms the summit of the arch, is a dense, fibrous structure of a crescentic shape, presenting a sharp, concave border towards the urethra, which traverses the triangular ligament a short inch below it. Between the urethra and the integument of the perinæum are the more yielding muscular and fascial layers of tissue. Now it is obvious that any violence applied to the perinæum in the way of contusion, would tend to crush the delicate structures which constitute the walls of the membranous divisions of the urethra against the upper border of the hole in the triangular ligament through which it passes, or against the sharp concave border of the sub-pubic ligament. The membranous division of the urethra is surrounded by a cylinder of very vascular, erectile tissue, derived from the *corpus spongiosum*, and, like it, inclosed by an elastic fibrous membrane, and a contusion of the perinæum produces a transverse wound of the mucous membrane lining this division of the canal, and involves the cylinder of erectile tissue which envelops it, just in proportion to the degree of violence of the injury.

We have recently performed some experiments upon the dead body, by bruising the perinæum and afterwards dissecting the injured parts, in order to study the nature and extent of the resulting lesion, employing different degrees of force in different subjects. The result varied with the amount of force employed. In some, the mucous membrane of the canal was marked by a narrow livid circle, with partial division of the membrane; in others, the mucous membrane was entirely cut through, and the erectile tissue exposed; and in others, again, the whole canal was cut across transversely, as with a dull knife, the external layers of tissue maintaining their integrity. The instrument used to bruise the perinæum was the broad end of an ordinary axe; and the degree of force employed in producing the lesion last described was less than you could have supposed.

You will infer from this statement that the usual seat of a stricture caused by perineal contusion is the membranous division of the canal; and this constitutes another point of difference between traumatic strictures as they ordinarily occur in practice, and the more common form of the disease following gonorrhœa. The latter, in accordance with the experience of the best observers, are most frequently encountered in the bulbous expansion of the spongy portion of the urethra, from 4½ to 5½ inches from its external orifice; the for-

mer, an inch, or thereabouts, further from the orifice of the canal.

The symptoms immediately following an injury to the perinæum which has involved the urethra, are first, bleeding from the orifice of the canal, which is almost always present, and generally spontaneous; second, difficulty in passing water, which exists always in some degree, and often amounts to complete retention of urine. When blood does not flow spontaneously from the urethra, the urine is always more or less tinged with it, frequently for several days after the accident, and in these cases the blood has flowed backwards into the bladder. But the remoter consequences of the urethral lesion are far more serious. These become apparent after a variable interval of time, often, in serious cases, within a month after the occurrence of the injury, and they are due to the contraction which accompanies the healing of the urethral wound. A gradually diminishing stream of urine; the necessity of a longer time and more effort to empty the bladder; and, sooner or later, indications of retention of urine, with other symptoms characteristic of urethral obstruction, announce the formation of a stricture, which is found, on examination, to be dense, unyielding, and generally sensitive to the contact of instruments.

These traumatic strictures constitute the worst cases of this disease which are encountered in practice; they are constantly occurring, and are very often badly treated. The opinion recorded by Civiale, the great French authority on diseases of the genito-urinary organs, you will find repeated, with very little variation, by all surgical writers who treat of the subject. He says, "These strictures are for the most part very serious; they are difficult to cure, and often irremediable by the ordinary methods of treatment." This statement accords entirely with my own experience. I have succeeded in curing but one case of traumatic stricture out of nine, by the ordinary method of treatment, viz. dilatation; and the fact that traumatic strictures are not ordinarily curable by dilatation is what makes them so serious. The difficulty of effecting a cure by the process of dilatation is due to several causes: first, the presence of dense, unyielding cicatricial tissue, of which the stricture is formed; which requires great patience to dilate, if indeed it can be dilated, which is not always possible, and which necessitates the constant employment of instruments to preserve the dilatation when secured, so great is its resiliency, or tendency to recontraction; second, the great liability to extreme sensitiveness in these strictures, which is an almost insuperable obstacle to the steady and persistent use of dilating instruments; third, the fact that traumatic strictures so frequently occur in young persons who will not keep up dilatations, when it has been accomplished.

Now as the ordinary method of *dilatation* cannot be relied upon for the cure of traumatic strictures, the question that interests you is—what other method of cure is available which promises better success? I answer, without hesitation, that the best chance of cure in most of these cases is by the operation of *perineal urethrotomy;* that which was performed upon the patient before you, and the successful issue of which, in his case, you can estimate by witnessing the readiness and facility with which he introduces for himself his full-sized sound.

As this case is somewhat classical in its features, I will give you a brief note of its history, deferring, for the present, what I have to say as to the mode of performing the operation.

W. S., a healthy boy of seventeen, messenger on board of a man-of-war, fell with one leg down a hatchway, striking his perinæum against its raised edge, but without a very great degree of force, on the 22d of February, 1864. He was immediately conscious of bleeding from the urethra, and lost, in a pretty continuous flow, about a gill of blood. He refrained from attempting to pass water, through fear of pain, for about fourteen hours, and then failing in the attempt, a catheter was introduced, but no urine flowed—apparently from clogging of the eyes of the instrument by coagulated blood. Half an hour afterwards, while lying in his bunk, a few drops of urine escaped involuntarily, but on rising and making an effort, the stream ceased; when he fell asleep shortly afterwards, his bladder relieved itself spontaneously, and for two days afterwards he passed a pretty full stream, but on the third day contractions commenced, and in two weeks afterwards he had retention again, but no instruments could be passed although attempted daily for two months, his urine being passed meanwhile with great pain and much straining, and only in drops. In this condition he was subjected to perineal section on the 19th of August following, and a No. 8 silver catheter retained in the bladder. Severe chills recurring daily the catheter was removed on the fourth day, and it could not afterwards be reintroduced; but the chills ceased, and the patient was able to pass his water partly through the urethra, and partly through the perineal wound. As the latter tended to heal, the urethral stream was noticed to be again diminishing in size, and at the end of three months it had become quite small, and the wound in the perinæum had contracted to a fistulous orifice which showed no further tendency to close, more or less urine escaping through it at each effort to urinate. On the 16th of December following, I saw the patient in consultation with Dr. Gouley at St. Vincent's Hospital, and recognising his condition as just described, and also that his stricture was apparently impassable by large or small instruments, I advised a repetition of the operation of perineal urethrotomy with the modifications to be detailed presently. After the administration of ether, I succeeded in passing a very fine filiform bougie, which I here exhibit to you, through the stricture, and into the bladder; and with this as a guide or conductor, the operation was satisfactorily completed. The urethra was divided longitudinally in front of and behind the stricture, in addition to the division of the stricture itself, so that a full-sized sound, No. 14, could be readily passed into the bladder; but no catheter was tied in the bladder, according to the usual custom of surgeons in this operation. The same sound was introdnced daily for five days, and after this every second day. He had no chill, or fever; the urine came freely through the wound until it closed entirely at the end of three weeks. To-day, you see, he has been well taught to introduce the sound for himself, and this capacity which he has acquired to act as his own surgeon, will render his cure permanent as long as he deals honestly by himself.

How far this mode of dividing a stricture from the perinæum will prevent subsequent recontraction, where a full-sized instrument is not systematically introduced at regular intervals by the patient, I am unable to tell you; but I am confident that it affords a better chance of escape from this misfortune than any other mode of treatment which is available. I hesitate in speaking to you more positively as to this point—the danger of subsequent recontraction—only because I have not watched the results of cases operated upon in this manner for a sufficient length of time as yet to warrant me in doing so. The feature in the operation upon which I mainly rely to secure this result is, the *free division of the healthy urethra in front of, and behind the stricture, in a longitudinal direction, in the median line, to the extent of at least a half-inch in either direction,* in addition

to the divisions of the stricture itself. This point in the operation is especially insisted upon by Mr. Syme, in the performance of the operation which bears his name, and which, in its general result, is identical with that which we are considering. He claims that it does always prevent recontraction, and bases his assertion upon the experience of over a hundred cases. But the credit of first demonstrating that thorough division of a stricture, together with the healthy urethra in front of and behind it, will prevent recontraction, belongs to the French surgeon Reybard, who asserted the fact as early as the year 1844, after long and careful study and experiment, and in 1852 received from the French Imperial Academy the prize bequeathed by the Marquis d'Argenteuil to the author of the greatest improvement in the treatment of stricture, amounting to $2,500.

I emphasize this point in the operation especially, because I believe that it explains the failure of the first attempt to cure the patient now before you; and I will endeavor to make this more plain when we come to the consideration of the second case. You will remember, in the note I have just read to you, that a catheter was kept in the patient's bladder, after the first operation, until the fourth day, when, in consequence of the daily recurrence of chills, it was removed; and after this it could not be again got to pass, and recontraction rapidly succeeded. Now, in my opinion, this recontraction was not due to the removal of the catheter, but to the absence of a sufficiently free division of the urethra before and behind the stricture at the time the latter was divided. In the second operation this free division was effected, so that a much larger instrument, No. 14, was admitted with ease, *and no catheter was kept in the bladder.* The large steel sound was simply passed daily, for the first five days, and afterwards every second day. Now this leaving a patient whose urethra has been freely divided from the perinæum, without a catheter tied in his bladder, is an innovation in the usual practice of surgeons after this operation; and as I am about to recommend you to adopt it as a measure which will render the patient's recovery more safe and speedy, it is but right that I should lay before you the reasons which appear to me to justify a measure which is somewhat bold as well as novel.

Twenty years ago I was called to a young gentleman of 21, who was suffering with sympt ms of extravasation of urine, and who gave me a history of long-continued difficulty and straining in passing his water. I found a very tight stricture in the membranous portion of the urethra, through which I was unable to introduce my smallest instrument, and ascertained that he had never had a clap, but had bruised his perinæum severely upon the edge of a chamber-vessel in early childhood. Fortified by the counsel of my friend, Dr. Gurdon Buck, I proceeded at once to incise his perinæum in the median line, and succeeded in dividing the stricture and introducing a silver catheter, No. 12, into the bladder, which I retained by a proper bandage, removing and cleaning it from time to time for nearly five weeks. He recovered entirely in about two months, and has remained under my observation ever since. I taught him to pass a steel sound for himself, and he uses a No. 10 at the present time; but I have had occasion very often to recognise the remains of the old stricture, and a distinct although not serious tendency to recontraction. This I attribute to my failure to divide the stricture more freely into the healthy urethra before and behind it. I also recognise very distinctly a hardness and rigidity of the walls of his urethra throughout its whole length; and this I attribute to the suppurative inflammation and submucous exudation caused by the long retention of the catheter in the canal.

Not long after this, in a case of impassable stricture with perinæal fistula, in which I did the same operation at Bellevue Hospital, and left a silver catheter in the bladder, an ulceration through the floor of the urethra, at the angle of junction of the penis with the scrotum, occurred in the third week from the pressure of the instrument. I find from examination of hospital records of similar cases, that this accident is not very rare at this point of the urethra. In consequence of the insertion of the suspensory ligament of the penis just opposite to it, this is one of the points in the canal upon which a solid catheter retained for any length of time in the bladder, is always likely to exert undue pressure. If I felt at liberty to cite the mishaps of others as well as my own for your instruction, I could detail to you numerous examples of serious injury resulting from the prolonged retention of the catheter in the bladder—flexible as well as metallic. Besides chills and urinary fever, and ulceration of the urethra from pressure, I have encountered instances of cystitis, calculous formation, ulceration of the bladder, and fatal peritonitis from this practice. Moreover, I have satisfied myself by personal observation, as well as by the study of recorded cases, that the presence of a catheter in the bladder after this operation, retards the healing of the perineal wound, and thus increases the danger of permanent perineal fistula. The convexity of a catheter of ordinary curve, unless the point of the instrument is projected into the cavity of the bladder further than is consistent with the safety of this organ, will make pressure more or less directly over the seat of the urethral incision; and this is especially the case in traumatic stricture, where the incision necessarily involves a part of the membranous portion of the canal.

Influenced by this experience, I had long since abandoned the practice of leaving a catheter in the bladder, after incision of the urethra through the perinæum, for a longer period than forty-eight hours; further experience and observation have recently satisfied me that it is better for the patient, unless in exceptional cases, that the catheter should not be left in the bladder at all—as in the cases which form the basis of these remarks.

In justification of this conclusion, I think, in the first place, that the experience of practical surgeons will confirm the operation, that the tying of a catheter, either metallic or flexible, in a man's urethra and bladder, is a proceeding always attended by more or less discomfort, and often with danger. In some cases, the instrument cannot be tolerated from the moment of its introduction; in many, pain and uneasiness are constantly present; in others, chills and febrile reactions necessitate its removal—as in the case before us. It is, therefore, to be regarded as an evil, in a greater or less degree. Now, in the second place, what is the compensating good which justifies the practice? It is the general impression, I believe, that the presence of the catheter in the bladder, by preventing the flow of urine through the newly-made wound, will obviate the bad consequences attributed to the contact of urine with a recently-cut surface, and will subsequently facilitate its healing; it may be, also, that extravasation of urine through the walls of the incision is apprehended by some.

I question the correctness of these views, on the following grounds: 1st, The presence of a catheter in the bladder does not prevent the escape of more or less urine through the wound, which almost invariably occurs in some degree, either at the time of the operation or subsequently. I have observed this fact in quite a number of cases, and it is mentioned in a large proportion of recorded cases. 2d, The consequences of contact of urine with the walls of a recent incision are not

serious, as is demonstrated after the operation of lithotomy. 3d, In the recorded cases which I have studied, the closure of the perinæal wound is certainly delayed by the presence of the catheter in the bladder; and it takes place most rapidly where no catheter is worn. Finally, a fistula following the operation of lithotomy is exceedingly rare, and here the urine flows through the wound from the moment of the operation. As to the danger of extravasation of urine through the walls of the incision, it is only to be apprehended where the deep layer of the triangular ligament, the pelvic fascia, has been divided; or, to the extent of a few drops, when the scrotum has not been properly supported after the operation—a precaution too often neglected. Abscess in the scrotum, generally trifling in extent, and occurring in the second week after the operation, occurs because the anterior extremity of the perinæal wound involves its base posteriorly, and in consequence of its depending position. I notice the occurrence of this accident in some of Mr. Syme's recorded cases. It may always be averted by the use of a sling bandage for two or three days, or until the wound has suppurated.

These, then, are the considerations by which I am induced to recommend you to adopt a practice different from that usually advised, after division of a stricture of the urethra from the perinæum. It remains for me to demonstrate to you, by the results of actual practice, that it possesses the advantages I have claimed for it. Besides the case of the boy now before you, which, in regard to this point of treatment, furnishes the most satisfactory evidence, Dr. Gouley, who, as far as my knowledge extends, was the first to adopt this practice, has also employed it with equally favorable results in other cases. And this brings me to the case of the carpenter who was the subject of the operation five days ago, whom I hope to bring before you in a fortnight or so, when we will study its progress and result.

Reports of Hospitals.

JEFFERSON MEDICAL COLLEGE OF PHILADELPIA.

Surgical Clinic, March 24th, 1866.

SERVICE OF PROF. GROSS.

URINARY CALCULUS—LITHOTOMY.

Wm. D——n, æt. 21 years, by occupation a collier, has suffered from symptoms of vesical trouble for eleven years; an examination with the sound reveals the existence of a stone apparently of a considerable size. His general health is pretty good, but he is somewhat pale. He has a good appetite, sleeps well, and is not obliged to pass water as frequently during the night as when up and walking about. He is unable to perform his work as a laborer, and suffers locally with the ordinary symptoms of stone in the bladder, such as difficulty in passing water, necessitating straining and bearing down in relieving himself, and the peculiar pain in the penis, which is always the result from the contact of the stone with the mouth of the urethra or the neck of the bladder. The penis of the patient is unusually large, the prepuce elongated and in a state of hypertrophy.

Whenever a patient labors under stone in the bladder, there is a constant uneasiness of the parts reflected to the anterior portions of the penis and the foreskin, which constitutes a prominent symptom. The individual is obliged to take hold of these parts, and they are often found, especially in children, completely sodden, as are also the hands of the patient; this condition being the result of maceration from the contact of urine. There is also in the patient presented, as is frequently the case, though not generally so, more or less of urinous odor, not occurring from any transpirations of urine, but from the fact that the urine is brought into frequent contact with the clothing, leaving its peculiar odor in this manner, and this odor is sometimes thought characteristic of the nature of the affection. During micturition, there is frequently, often constantly when the stone lies loose in the bladder, a sudden arrest of the flow of urine, caused by the calculus coming into contact with the mouth of the urethra and occluding the orifice, so that the patient is obliged to change his posture for a position favorable to effect a change in the position of the stone before he can evacuate his bladder. He may have to lie down, or to sit down, or elevate his hips, or assume some other position; sometimes it is necessary for him to bend his body forwards until his head comes in front of his thighs.

In consequence of the constant straining in many cases of urinary calculi, the patient is apt to suffer from *hæmorrhoids*, and from *prolapse of the bowel*, especially in children and elderly persons, in whom the parts are easily relaxed. *Hernia* is not uncommon in these cases, brought on merely from the immense amount of straining to which the patient is subjected during the process of micturition. Sometimes there is *hydrocele;* occasionally *orchitis;* and not unfrequently *neuralgic pains in the sacro-lumbar regions.*

Though a patient with stone in the bladder may be in very good health, his system becomes deteriorated after a time; he becomes susceptible to atmospheric changes, ultimately becomes dyspeptic, emaciated, worn out by the disease of the bladder; the mucous membrane of the bladder may take on inflammation; there may ensue hypertrophy of the organ; inflammation may extend along the ureters to the substance of the kidneys, and, if not relieved, the patient may die from the affection.

The patient presented to the class is from a region of country where the water is freestone, and, what is somewhat remarkable, Dr. Gross has had under treatment ten or fifteen cases from that region, all within a narrow compass. The opinion was formerly very prevalent, and perhaps is still so, that calculous diseases are most common in limestone regions, because the subjects drink lime-water. Dr. Gross is not prepared to endorse this view. It is certain that, in this country as well as in other countries, stone in the bladder is most frequent in regions of that description; but it is not proper to claim that the habitual use of limestone water exerts any influence on the induction of the disease. The fact, if it be one, has not yet been established. In his own experience, Prof. Gross has known numbers of instances where stone has been developed in individuals residing in regions of country where the water was entirely freestone in its character. He had several cases from Georgia, where there is no limestone water.

The most common variety of calculus is the *uric acid* calculus. In this, and also in other countries, the *phosphatic calculus* is exceedingly uncommon, and is met with chiefly in persons who have experienced injury of the spinal cord. The *oxalate of lime calculus* is uncommon in this country, as is also the *ammoniaco-magnesian* variety. The great majority of calculi are of the nature of the lithic acid or uric acid variety. There are other varieties of calculi besides those mentioned, but they are also exceedingly infrequent.

This disease is liable to occur at any period of life. It is sometimes congenital, sometimes makes its appearance soon after birth. The youngest patient Prof.

Gross ever cut for stone was an infant about fifteen months of age, operated on before the class some ten years ago. He has performed the operation repeatedly on children before they had reached the age of three years. The best subjects for the operation are young children and elderly persons. Dr. Gross has performed the operation on patients upwards of eighty years of age. In one instance, he removed five calculi, of variable dimensions, from the bladder of a gentleman seventy-three years of age, who had considerable enlargement of the prostate gland, and who recovered without a single untoward symptom.

The operation to be performed in preference to any other is the *lateral operation*, so called because the incisions are made on the left side of the middle line of the perineum. The incision should begin about one inch above the verge of the anus, just on the left side of the raphe, and be carried down obliquely outwards and backwards, nearly midway between the anus and the tuberosity of the ischium, but nearer to the tuberosity than the anus, so as to terminate a short distance below the verge of the anus. The incision should not be more than one and three-fourths or two inches in length. Prof. Gross formerly made longer incisions, but now finds advantage in making his incision small, and has experienced no ill effects from infiltration of urine or otherwise since he has adopted this plan. The size of the incision made in the adult by many surgeons is three inches or three and a quarter inches in length. The surgeon makes his first incision through the skin and superficial fascia; in the next place, introducing the left index finger in the upper angle of the wound, he carries the knife through the transverse perineal muscles, dividing, of course, the transverse perineal artery running along its posterior border; he divides the deep layers of the perineal fascia, some fibres of the elevator muscle, the transverse ligament, and the membranous portion of the urethra, to the extent of about three or four lines, sufficient to enable him to introduce the point of his index finger, which is brought into contact with the groove of the staff; he inserts his instrument into the groove, and divides the left lobe of the prostate gland in a direction obliquely downwards and outwards, which is that of its long axis. He imparts a horizontal direction to his knife, so as to avoid interfering with the rectum, which is pushed towards the right side with the finger.

This constitutes the operation of lithotomy, divided into three stages, for the sake of convenience of illustration.

When the perineum is large, loaded with fat, presenting great depth; and when it is very narrow, as is not infrequent, especially in elderly subjects, the operation is embarrassing and even difficult; but under ordinary circumstances it is sufficiently simple.

The knife employed by Dr. Gross is a slightly spear-shaped, sharp-pointed bistoury, cutting at one edge. It is a very delicate instrument, the blade being three inches in length, and a trifle over two lines in width. With this knife the entire operation is performed. The staff employed is catheter-shaped, and always sufficiently large to distend the urethra moderately; the handle is large and rough, to enable a good hold to be taken, and the vesicular extremity is rough; the groove is deep and wide, and placed a little towards the left side; it is warmed, then oiled, and introduced as an ordinary catheter would be. It is held firmly under the pubes by a trustworthy assistant, and hooked up under the arch, with a very slight inclination of the handle over towards the right side. Care must be taken that it be not pressed upon the rectum, lest that tube be interfered with. The instrument must be securely lodged within the bladder.

In performing the operation of lithotomy, if the incisions made have not afforded sufficient room for the extraction of the calculus, the parts should be lacerated by means of the finger to the necessary extent.

The moment the incisions have been made into the bladder the urine gushes out in a full stream, and the stone is propelled down against the upper extremity of the wound. The surgeon introduces the forceps into the bottom of the wound, and carries the instrument into the bladder. When it comes in contact with the substance the blades are expanded, a firm grasp taken of the stone, and an effort made to effect extraction on the same principle as the head of a child is extracted in labor, moving it from side to side and forwards and backwards. After the extraction of the calculus the bladder should be washed out with tepid water, thrown in a full stream from a large syringe.

Sometimes it is necessary to divide the right lobe of the prostate to a greater or less extent; but such a necessity rarely presents itself.

Hæmorrhage may occur merely from division of the transverse perineal artery, which occasionally becomes considerably enlarged, and affords a large flow of blood. Or the superficial perineal artery may be divided, as rarely happens, and that may bleed; or the artery of the bulb may be divided. This is a short, thick, stunted trunk, situated deep down between the layers of the triangular ligament, and is cut sometimes when the incision is made too high up.

There may be serious hæmorrhage, even to a fatal extent, where there is an anomalous distribution of the internal pudic artery running along the side of the left lobe of the prostate, when the knife cannot avoid it.

Before operating for stone, the patient should be subjected to some necessary preparatory treatment; and shortly before the operation the bowels should be emptied, because it will be necessary that there should be no motion of the bowels for some days after the operation. As it is of importance that the bladder should be full during the operation, the patient is always directed to hold his urine for several hours.

After an operation for stone, the surgeon experiences considerable anxiety for the first twelve or fifteen hours, for fear of hæmorrhage. If the urine comes away kindly, not blocked up by coagula, it is a favorable indication. If coagula are expelled from time to time, it is evidence that bleeding is going on, and this is not always easily arrested. Hæmorrhage is to be arrested by ligature or torsion, and, when this is impracticable, by compression. A canula pierced with two holes at its perineal extremity, to secure it to a proper bandage, is introduced into the bladder, and serves to compress the bleeding vessel, and also conduct off the urine. This, of course, will interfere with the union of the wound. Styptics, cold water, exposure to the air, etc., may serve to arrest hæmorrhage.

Dr. Gross gives his patients some sulphate of morphia before he operates, and as soon as they revive from the effects of the chloroform, which is the anæsthetic he employs, he gives half a grain more. Patients who have been operated upon for stone must be treated antiphlogistically. Spasmodic bearing-down pain comes on until the urine finds a free outlet, when it gradually subsides. Dr. Gross does not introduce any tube into the bladder to conduct the urine off. He considers this altogether unnecessary. The tube retained in the wound cannot fail to act as an irritant to the parts and provoke spasm.

The patient before the class was operated upon in the manner described, and a large lithic acid calculus

extracted, weighing nearly two ounces, and measuring two inches and a half in length, two inches in width, and one inch in thickness.

NEW YORK ACADEMY OF MEDICINE.

STATED MEETING, MAY 16, 1866.

Dr. JAMES ANDERSON, President, in the Chair.

Drs. S. W. FRANCIS and F. H. HAMILTON were complimented by a vote of thanks for their several donations to the Academy of fifty-nine illustrated volumes of the *Dictionnaire des Sciences Medicales* and two volumes of Dr. Hamilton's work on *Military Hygiene*.

RESECTION OF THE ELBOW-JOINT.

Dr. POST, for the purpose of showing a result which some might never have an opportunity of seeing, introduced a lady, now in her 21st year, who had been the subject of an operation by him when ten years old. About a year before this the patient had received a violent injury of the left elbow-joint which had been neglected, and which, in his opinion, was essentially a fracture, but of what character he could not determine. At all events, the resulting anchylosis which prevented her carrying the hand to the mouth was firm though not bony. For the relief of the difficulty he resorted to a longitudinal incision upon the posterior side of the limb, and removed about one-half inch of the *os brachii* at the end; but this not having secured the requisite mobility, he took away at the second operation about one inch more. He preferred the single longitudinal incision, notwithstanding its difficulty, to the transverse method, because by it the fibrous structure which contributes so much to the strength of the articulation was not divided. Both bones of the forearm remained undisturbed at each operation. Her deformity amounts to a shortening of about two inches, and a certain attenuation of the limb, but these deficiencies are more than counterbalanced by the restored functions of the joint; she can carry a pail of water and perform her household duties quite comfortably.

THE RESULT OF A CHEILOPLASTIC OPERATION.

Dr. BUCK presented to the notice of the Academy two plaster casts and several photographs by way of illustrating the results of two operations for the relief of a deformity consequent upon a shell wound received during the month of September, 1864. This patient he had been privileged to operate upon at the Central Park Hospital during the succeeding February by the courtesy of Surgeon B. A. Clements, U.S.A., then in charge. The patient's mouth was then quite contracted, his under lip drawn in, adhesions and cicatrizations interfered with both articulation and deglutition, and he was compelled to wear a tin gutter underneath the chin to carry off the constantly-escaping salivary secretion. He had removed the right half of the lip and detached the remainder. This and other details occupied two hours or more, but notwithstanding the loss of blood, which was considerable, and the continued anæsthesia by ether, his pulse was not at all depressed. In eight days the sutures were all removed. The result of the whole was an improvement in mastication and articulation as well as a confinement of the saliva to its proper office, but the mouth was defective in symmetry, three-fifths being on the right side, and the remaining two-fifths on the left. He, therefore, induced him to return to the city, and, in January last, resorted to a second operation, by which that difficulty was overcome, while the recession of both lips, which was due to the loss of the front teeth by the original accident, was remedied by the ingenuity of Mr. Bishop, of Twelfth street, who adapted a plate to both maxillæ.

MEASURES FOR THE PREVENTION AND RELIEF OF CHOLERA.

Dr. STEPHEN SMITH read a paper entitled as above, in which, after demonstrating that the too often neglected preliminary diarrhœa was curable, he advocated "house-to-house visitation." This plan, and the inducements held out to the poor to seek relief for the slightest derangements of the bowels at the various charitable institutions, denominated for convenience sake "Medical Centres," had proved, as shown by statistics, eminently successful. Transportation of patients to far distant hospitals had been attended with a greater amount of mortality than treatment at patients' homes. For this and other reasons he favored small hospitals in the locality of the epidemic. He also advised temporary accommodations for the poor while their abodes were undergoing purification.

This paper, on motion of Dr. BATCHELDER, was referred to the Council for publication, after which the Academy adjourned.

NEW YORK PATHOLOGICAL SOCIETY.

STATED MEETING, JAN. 25, 1866.

DR. FRANK H. HAMILTON, President, in the Chair.

GUNSHOT WOUND OF BLADDER—A CALCULUS WITH A FRAGMENT OF BONE FOR NUCLEUS, ETC.

DR. LIVINGSTON presented a specimen removed from the bladder of a man whose history he gave as follows: The patient, 26 years of age, was wounded in the battle of the Wilderness, May 2, 1864. The missile was supposed to be a minié ball. It entered the body near the right inguinal ring, and passing through the bladder, made its exit near the median line through the centre of the sacrum. He lay upon the field some five weeks without any treatment, and in the hands of the enemy. The only shelter he had was a canvas screen. He kept the wound cleansed by the use of cold water. The urine then passed constantly through the anterior opening. About the 10th of June he was removed to Lynchburg, where he was under the care of Dr. Chalmers. About the first of July the urine began to pass through the urethra, and by the middle of the September following the anterior opening was entirely closed, all of his water passing through the natural channel. The posterior opening, of which very little notice was taken, must have also closed by this time.

About the first of December, after having suffered from chronic diarrhœa for six weeks, he was transferred to a hospital at Annapolis, in which institution he continued until the first of January, when he was discharged and sent home

In the middle of September, about the time the anterior opening closed, he began to experience the first symptoms of stone in the bladder. These symptoms continued to increase in severity while at the Annapolis hospital, but no particular attention was paid to them by his attending surgeon except by the occasional administration of a diuretic. He continued to grow worse up to the sixth day of August last, having in the meantime received no treatment or counsel whatever. That day I saw him for the first time, he was then spending the whole

of his time endeavoring to relieve his bladder, being able to urinate only by drops. There was a large abscess seated in the lower part of his abdomen; he was in a very low condition, and was evidently destined to live but a short time. The seat of the anterior wound was covered only with a slight membrane, which, after protruding a half or three-quarters of an inch during every effort to expel urine, would at length give way, allowing the water to escape by the opening thus formed.

A sound was passed into the urethra, and at the membranous portion of the canal came in contact with a hard substance; and on passing beyond this point, another hard substance of larger size was encountered. The indications were then clear enough; the abscess was immediately emptied and a poultice afterwards applied; stimulants were freely given; and from the very fact of overcoming the obstruction in the urethra by the passage of the instrument, the irritation of the bladder was in a measure relieved and the patient enjoyed a little rest. On the 18th of August his condition was so much improved that it was determined to remove the foreign body, which was of course supposed to be a calculus. On that day, assisted by Prof. Markoe and several other medical gentlemen, I removed this stone. I did this by the median operation. I selected that operation for two reasons. In the first place, his condition was so low that every drop of blood was a matter of a good deal of moment to him; in the second place, being satisfied that there was something within the membranous portion of the urethra immediately behind the bulb, I thought it better to open the urethra by the median line. Almost immediately after the operation, this little fragment, which proved to be bone, was felt in the membranous portion of the urethra. The operation was very simple; the stone was readily grasped and with very little effort extracted. I would here make one remark in connexion with this operation. Great stress has been laid upon the difficulty of removing calculi of any size through the prostate; in this instance there was no difficulty whatever, except only so far as it related to the cellular and integumentary tissue in that locality. Immediately after the stone was removed, a piece of bone of larger size than it, floating around free in the bladder, also came away. After finding that nothing further remained, I syringed out the organ with water, and afterwards applied cold-water dressing to the wound. In the course of ten days afterwards the urine passed entirely through the urethra, and the patient was able to walk about the room. About six days ago he called at my office to tell me that he had not the slightest pain or annoyance in urination since the operation. The ball must have struck the upper border of the pubic bone and chipped off some small fragments, which were driven into the bladder; and around one of these pieces, as is proved by the calculus here sawn open, the calcareous matter was deposited. There was no doubt but that the nucleus of the stone was bone.

Dr. Lidell remarked that the case, so far as his knowledge extended, was a unique one.

Dr. Hamilton stated that a number of cases were recorded in which balls found an entrance into the bladder and lodged, but he had never heard of an instance in which fragments of bone had been driven into the organ in the manner described by Dr. Livingston.

Dr. Livingston said that there were no other evidences that the bone had been injured than were presented by the appearance of the calculus, and by the positive statement of the patient himself.

CASES OF OSTEO-MYELITIS.

Dr. Lidell presented several interesting specimens of osteo-myelitis, and gave the following account of them:

This came from a patient who had suffered a gunshot fracture of the thigh, for which he was admitted into Bellevue Hospital on the 28th of September last, having been wounded on the previous night. The femur was fractured at about its middle. He was treated with Buck's apparatus for about eight weeks, and seemed to do well; but at the end of that time, when the apparatus was removed, union was found not to have taken place. It was also found, on exploring the wound, that there was a piece of detached bone in the interior of the thigh. A short time after, this was removed by operation. After that the case was treated with sand bags, together with a moderate extension of four pounds weight. It was soon noticed that the appearance of the soft parts was not so good as it had been, that the granulations were becoming changed in color and were paler than usual, and that the patient's health was beginning to be impaired. His appetite was getting poor, and he complained of feeling weak. After this he took pyæmic sweats, then his skin became sclerotic; he then was attacked with diarrhœa, and soon sank into a typhoid condition. He then had many of the symptoms which pertain to osteo-myelitis. I will mention one—that of *pain*—and say that according to the statement of the House Surgeon, it did not seem to constitute a prominent symptom at any time. He had pain in the thigh, which might be as well referred to the inflammatory mischief going on in the muscular tissue as to anything else. He died on the 4th of January. The autopsy was made ten hours after death, at which, besides infiltration of the soft parts of the thigh, there were abscesses in both lungs and sero-purulent effusion in both pleural cavities.

I hold in my hand the superior portion of the thigh which has been sawed open. On looking at its exterior you see about it a considerable quantity of new osseous deposit. Attached to one side of it you see a large fragment of new bone; this portion bridges over the chasm between these two fragments. It is still attached to the moiety of bone. Above this new osseous deposit the periosteum was thickened, loosened, and reddened. The surface of the bone is also roughened; the longitudinal grooves are much larger and deeper than normal. The surface of the bone is somewhat redder than natural. On examining its interior, the medullary cavity is seen to be the seat of an enormous abscess, extending from the fractured extremity up to the cancellated structure of the superior epiphysis, surrounded by red marrow. The suppuration extended far up into the cancellous structure, even to the cancellar border of the bone. The so-called abscess was examined, and found to contain pus. The red medullary tissue was found to contain granular marrow cells in great abundance—an increased amount of connective tissue with spindle-shaped marrow cells. The interior moiety of this thigh has upon its external aspect a considerable quantity of new osseous deposit. Continuing the examination of the exterior of the bone, we find the periosteum, in the neighborhood of the new osseous deposit, red and thickened. It was not detached, except at points here and there. Examining the interior of the bone, we found the medullary canal at the fractured end of these fragments closed by a new osseous deposit. Proceeding further down, we found an opening in the nature of an ulceration extending from the exterior of the bone through into the interior of the medullary canal. A little further down we discovered a piece of old bone which had been driven into the medullary canal by the projectile. Lower still the medullary tissue was of a light red color throughout, except at the epiphyseal extremity, where it was a little yellow. The microscopical examination of the red marrow showed it to consist of highly granular marrow cells, mostly having but one nucleus, a small amount of

connective tissue, a few fibrous cells, blood-vessels, a few fat vesicles, and some free fat. The seat of the slough examined by the microscope was found to consist of granular matter, connective tissue, and free oil; the walls of the fat vesicles being broken down by the destructive process.

The next specimen is one of osteo-myelitis, which, like the preceding one, also occurred in the practice of Prof. Hamilton, in Bellevue Hospital. This patient was 28 years of age, and was admitted on the 22d of December, on account of a chronic diseased condition of the elbow-joint, having a traumatic origin. This man had suffered an injury of his elbow-joint, in the nature of a contusion inflicted by the recoil of a gun. This was followed by suppuration of the joint and surrounding soft parts. As the result, the joint was left in a carious condition, for which it was judged advisable that exsection should be practised. On going through the steps of the operation, however, and on cutting through the upper extremity of the radius, pus escaped; a second section through another portion was followed by a like result, whereupon it was deemed necessary to make an amputation higher up, which was done. On the following day pyæmia supervened, and the man sank afterwards and died on the seventh day after, of pyæmia. At the autopsy visceral abscesses were found in both lungs, and sero-purulent fluid in the left pleural cavity.

Examination of this bone shows the medullary tissue to be inflamed, and to present a decidedly striking contrast to the other case.

Looking at the exterior of this bone, you do not see any new osseous deposits. The periosteum, however, is detached for the distance of an inch and a half in some situations, and an inch and a quarter to an inch and a half from the sawed extremity of the bone upwards. Here the periosteum was reddened and considerably thickened. I may say, likewise, that the loosening of the periosteum extended some distance above the place of complete separation. Where separated, the periosteum was pale, dry, and of the yellowish-white color of necrosis. On opening the medullary canal by a longitudinal section of the saw, the marrow was of a copper-red color, firm and flesh-like; it was so firm, that upon its surface it left wave-like lines after the saw. On introducing the handle of the scalpel between it and the bone, you could lift it all out as one piece of flesh. At the divided end of the stump bone it had a darker color, and was detached to some extent from the surrounding osseous wall. On examination by the microscope, this red marrow was found to consist in great part of a moderate amount of highly granular marrow cells, some with two, three, or four nuclei. Higher up, about opposite the surgical neck of the bone, the parent marrow cells were more numerous, and one was found containing as many as nine nuclei. There was also in this specimen of marrow a large quantity of fat vesicles, which accounts for the yellowish hue of the substance.

I have still another specimen of inflamed marrow, which contrasts strongly in some respects with the specimens already exhibited. This comes from a case of compound fracture occasioned by a railroad accident, which was treated at St. Vincent's Hospital. The young man was admitted to that house on the 14th day of November, having sustained an injury, fourteen days previously, between the bumpers of the cars. About two weeks after the accident pyæmia set in, with which he lingered until the 12th of January, when he died. At the autopsy, the cadaver was very much emaciated; the right thigh, which was the fractured one, was greatly swollen. On cutting open both the thigh and the leg, the limb was found extensively infiltrated with pus. The pus burrowed downwards into the popliteal space, into the leg and knee-joint, which was found to be stiffened by a process of anchylosis which was going on. The bones were in the condition which you will see here. There was no effort at union, the fractured ends being irregularly rounded off. You will observe also on each of these fragments new osseous growths in the nature of periostosis. On the upper fracture, above the seat of the new deposit, the periosteum is red and thickened, but not detached. You notice the same grooves which were seen in the first case, and which are so indistinct in the natural state. On cutting it open the marrow was seen at the lower end of these fragments to be gangrenous. The sphacelus was of a brown color, but had not proceeded so far as to make the marrow break down. Proceeding upwards in the medullary canal we find a new osseous deposit, following which we also find that the marrow becomes paler. Higher up again it is deeper in color, until at the end we find it a deep brown. The marrow was softer than in the other cases. In the inferior fragment the marrow had a pale red color.

But the most interesting feature was the condition of the joint. Here we see anchylosis occurring by a new osseous development from the articular surfaces of the femur. I may say that this joint, on being first opened, presented a deep red color, most intense at the point where the new osseous growths were taking place—very intense at the patella, which is already adherent to the femur.

I have still another specimen of osteo-myelitis. A young man aged 25, of robust and healthy parents, was admitted into Bellevue Hospital on the 9th January, 1866, in the service of Dr. Sayre, with a compound complicated fracture of the leg, resulting from a railroad accident the day previous. There was a lacerated wound on the inner side of the leg, about three inches in length, which communicated with the bone by a small orifice. There was no other wound, but all the soft tissues were very much contused. His general condition was good—suffering very little pain. "Jan. 11, limb very much ecchymosed, and more swollen. Jan. 12, pulse hurried—tongue furred—no appetite—limb swollen and tender—discharge of bloody serum from wound. Jan. 16, pulse 100. Erysipelas has attacked the limb, extends nearly whole length of thigh—sloughing of skin on outer side of leg. Jan. 17, line of demarcation formed. Gangrene of superficial tissues from below knee to a short distance above ankle on outer side of leg. Jan. 18, pulse 104—vomiting—large slough removed—tendon of muscle and fragment of fibula exposed. Jan. 19, pulse 90, slight delirium during night—vomiting continues. Jan. 20, pulse 90, tongue dry and furred, erysipelas disappearing from thigh—vomiting has ceased. Jan. 21, pulse 90. General appearance of limb is better, although there has been an immense destruction of tissue. 8 P.M., pulse more feeble. From this time he continued to grow worse, and died Jan. 22d, at 5 A.M."

I have read the history of this case to you for the purpose of showing that the patient did not die of those pronounced symptoms which we are in the habit of calling pyæmia.

We here see the protruding red marrow of the inferior fragment. Examined exteriorly, we have thickening, reddening, and detachment of the periosteum. No doubt, by sawing open the bone, the marrow will be found in an inflamed condition throughout.

In the case of the first specimen, there was pyarthrosis of the hip-joint. The cartilage of incrustation of the head of the femur was not discolored, though at two

or three points it presented an appearance as if holes had been punched through it, and that the cancelli underlying these holes were suppurating; and it appeared to us that the morbid process had extended from the interior of the cancellated tissue into the interior of the joint by this method.

Dr. Hamilton remarked that he had taken a great interest in the first case described by Dr. Lidell. The failure of Buck's apparatus was not due to any separation of the fragments, as they were found overlapped more than half an inch. The fact is, the patient had been for a long time suffering under chronic diarrhœa; the bone was much comminuted by the ball, and several fragments had been removed before he came under Dr. Hamilton's notice. The amount of extension employed had never exceeded twelve pounds, and during most of the period it has been much less.

CYSTIC DEGENERATION OF THE KIDNEY.

Dr. Reynolds presented a specimen of cystic degeneration of the kidney which had been sent to Dr. Clark from the Kings Co. Hospital, with the following history:

The patient from whom these kidneys were taken entered Kings Co. Hospital, January 15. She seemed rather foolish, and when questioned as to her complaint would answer "*chills.*" As far as could be learned from her, she had suffered from them for three months, and nothing more could be elicited concerning her case.

The third day after entering hospital she was taken with convulsions, and in a few hours became profoundly comatose. She remained so for forty-eight hours, and died. At post-mortem the kidneys were found in this state—one weighing *two* pounds and *four* ounces, the other *one* pound and thirteen ounces. She complained of no pain whatever, and the urine, though of less quantity than would be expected, seemed to be of the natural color and clearness. Nothing particular was noticed about the other viscera.

ANEURISM OF ARCH OF AORTA.

Dr. Reynolds also presented an Aneurism with this history:

Sarah Peterson (colored), aged thirty-eight, had suffered with pain in the chest for past five years, which was attributed to neuralgia. In November, 1864, the pain became more intense, and on examining her chest she discovered a small lump, the size of a black walnut, a little to the right of the upper portion of the sternum.

Dr. Parker saw her in December, and pronounced her trouble aneurism of arch of aorta. Dr. Clark saw her shortly after, and confirmed the diagnosis.

The tumor increased gradually in size till January 16th, 1866, when death was caused by exhaustion and interference with respiration. Shortly before death the tumor measured 18 inches in circumference at base; 6½ inches vertically and 6¼ inches transversely. There was no murmur audible anteriorly at any time, but over the spinous process of the cervical vertebræ a blowing murmur could be distinctly heard.

REMOVAL OF PISTOL BALL—USE OF ACUPUNCTURE NEEDLE.

Dr. Buck then presented a pistol ball, which was only interesting from the manner in which it was extracted from the wound by the successful application of the acupuncture needle. A colored man while carrying a pistol in his fob found it slipping out, and in attempting to push it down it discharged its contents into his groin immediately below Poupart's ligament, just two inches outside of the femoral. On introducing a probe into the wound of entrance, it followed a track over the inner condyle and a little above it, and at its bottom a firm body was encountered that was about the size and shape of the missile that was supposed to have been lodged there. This body could be slipped within a certain limit, and its movement would cause pain. Presuming that it was the ball, there was not certainty enough in the diagnosis to warrant an attempt at its extraction until the acupuncture needle was used. This was passed down in the situation of the deep-seated lump through the tissues, and encountered the foreign body. By certain manipulations it was found to escape from the point of the instrument and roll aside, which fact left no doubt in the mind of the presence of the projectile at that point. It was then cut down upon by a narrow-bladed knife, and removed without difficulty. Dr. Buck remarked that his attention had been first called to the needle by seeing a published account in some of the medical periodicals of its use by a Scotch army surgeon, whose name he did not recollect. Dr. Buck also stated in this connexion that he had employed the same procedure with success in discovering the existence of a calcareous body impacted in the prostate gland. The needle in this instance was curved, and was introduced into the gland upon the finger as a guide. The needle is very fine, and has a trocar point in order to facilitate its entrance into the tissues. The society then adjourned.

The International Sanitary Commission in Constantinople.—A correspondent under the date of 24th, writes from Constantinople that "the members of the International Sanitary Commission have resolved into two factions—English and French—the former headed by the Secretary of the English embassy, Mr. Stuart, formerly of her Britannic Majesty's legation at Washington.

"The chief subject of discussion is that of a quarantine to be placed upon all vessels arriving at the eastern ports of the Red Sea from those of British India. As the pilgrim passengers which these convey are all subjects of her Britannic Majesty's possessions in India, such a detention naturally affects them most. Some of the members hold that the epidemic can be checked and arrested by rigid quarantines and by thorough fumigating, while others, in the minority, say that, being an epidemic, it is not transmissible by contact with infected clothing or by diseased individuals. The question of a quarantine deeply interests also the Persian and Turkish pilgrims. The former, after visiting the Islam, sacred tombs of Mersched and Kerbellen, on the Persian-Ottoman frontiers, proceed by land to those of Mecca and Medina; and the latter travel hence (at least many do) through Asia Minor to Damascus, and thence to the holy cities just named. If the epidemic be introduced into Persia from India, or by the Persian gulf, it may be carried overland into the Hedjaz: but it will, most probably, be taken direct by sea to the ports of the Red Sea.

"The French have also a large number of pilgrims from Algeria visiting the Hedjaz through Egypt, and the works on the Suez Canal might be seriously retarded by the reappearance of the cholera in Egypt, and hence the conflicting reports of the French and English despatches.

"The small commission sent some months ago by the Porte direct to the Hedjaz for the purpose of ascertaining whether or not the remains of the sacrifices are there left exposed to the sun or concealed beneath the soil has reported in the latter sense. This is believed and just proven by the English deputation as a fact, but none others believe in its truthfulness."

HOSPITALS FOR THE INSANE.

THE question of distance and nearness, as they respectively influence the use of hospitals for the relief of insanity, is well put in an able and convincing paper, by Dr. Edward Jarvis of Massachusetts, in the *American Journal of Insanity*. The discussion was suggested, evidently, by the recent legislative action of New York, establishing a second State Hospital to be devoted to the incurably insane, and, like the institution at Utica, to be centrally located. These benevolent retreats are opened alike for all the people of the State. Yet the result is that distance is, to a large extent, actual exclusion from their benefits, so that every state hospital becomes, in some measure, a local institution. This, indeed, is what we might expect. "No liberality of admission, no excellence of management, no power of reputation, can entirely overcome the obstacles of distance and expense, the difficulty of transporting lunatics, or the objection of friends to sending their insane relatives far from home, and beyond the reach of ready communication."

To show that this probable result is the actual result, and that it follows with the certainty of a universal law, is the object of Dr. Jarvis's essay. He has subjected the question to the test of statistical accuracy and of mathematical exactness. To show, for instance, the actual operation in New York, he divides the whole State into four districts. Oneida county, which holds the great asylum, is number one. Number two contains eleven counties, mostly within sixty miles of Utica. The third district includes seventeen counties, which are from sixty to one hundred and twenty miles distant. The fourth district is composed of all the remaining counties, which are from one hundred and twenty to three hundred and fifty miles from Utica, excepting New York and Kings, which have hospitals of their own. The asylum at Utica has been in operation twenty-three years. The number of patients sent to it from each of the districts has been ascertained. The annual population of each district during the period has been carefully determined. Then, dividing the sum of the annual populations for twenty-three years by the number of patients sent in that time, we get the proportion of patients to population. Here is the result.

No. I. (Oneida Co.),	one	patient	out	of	2.772
" II.	one	"	"	"	5.820
" III.	one	"	"	"	7.351
" IV.	one	"	"	"	11.535

In other words, and in round numbers, we may say with sufficient nearness, that while Oneida (number one) sends *four* patients to the asylum, number two sends *three*, number three sends *one and a half*, and number four only *one*. Of course, there is not a shadow of reason for supposing that those districts which send the most patients to the asylum, have any larger proportion of insanity than those which make less use of its advantages.

To show that this is not an accident or peculiarity of our State alone, but that it is a necessary law of nature or humanity, Dr. Jarvis gives the result of similar inquiries into the hospital records of other States. Twenty-two States and two of the British Provinces are included in these calculations and statements. The investigation, which must have involved great labor and minute calculation, exhibits in all these States, a condition of things very similar to what has already been stated in regard to New York.

In some of the States referred to, the disadvantage of remoteness has been in part removed by the creation of additional hospitals. Massachusetts, for instance, though small in extent, when compared with many other States of the Union, has three public hospitals for her insane, besides the large and well endowed institution at Somerville.

The inference and the lesson which we should draw from these facts, are as clear as anything can be. We have some ground for believing that the community are awaking to a sense of what they owe to the insane. The late action of the New York legislature in regard to a hospital for the insane, to be placed somewhere on the Hudson, is full of hope and promise. That it will result in the establishment of a valuable and highly useful institution, we do not permit ourselves to doubt.

Under this act, commissioners are to be appointed who will locate the hospital. They may receive proffers of land and of material aid, and have power to contract for a suitable site. They are to make report of their doings to the legislature within ten days from the opening of the next session. Facts already stated show beyond a question, that the vast population of eastern and southern New York have a direct and most important interest in the successful prosecution of this enterprise. It will be strange indeed if it fails to receive hearty welcome and cheerful coöperation. We shall await with no common interest the appointment and the action of the commission. Meanwhile, we commend the object to the earnest consideration and efficient aid of all who may feel that they are directly or indirectly interested in its accomplishment.

The bill as originally brought before the Senate, giving extraordinary power to the Secretaries of War, the Navy, and the Treasury, "to prevent the introduction of the cholera into the United States," finally passed both houses of Congress in the following modified form:

"*Resolved, By the Senate and House of Representatives of the United States of America in Congress assembled*, That the Secretary of the Treasury hereby is authorized to make and carry into effect such orders and regulations of quarantine as in his opinion may be deemed necessary and proper, in aid of State or municipal authorities, to guard against the introduction of the cholera into the ports of the United States; and the Secretary of the Treasury is further authorized to direct the revenue officers, and officers commanding revenue cutters, to aid in the execution of such quarantine and health laws as may seem necessary."

This bill having received the signature of the President, has already become a law, but its exceedingly mild provisions and the merely discretionary power with which it invests a government official, will not, in all probability, give it any more force than "a paper blockade." Furthermore, just previous to its passage, an amendment was agreed to as follows:

"*Provided*, That all authority hereby granted, shall expire on the first day of January, 1867."

Reviews.

A Practical Treatise on Urinary and Renal Diseases including Urinary Deposits, illustrated by numerous Cases and Engravings, by William Roberts, M.D., Fellow of the Royal College of Physicians, London; Physician to the Manchester Royal Infirmary; Lecturer on Medicine in the Manchester School of Medicine. Philadelphia: Henry C. Lea, 1866.

The design of this work, by Dr. Roberts, "is to give an account of the organic diseases of the kidney, and of those disorders of which the chief characteristic is an alteration of the urine."

The author divides it up for convenience into three parts. The first, which may be regarded as introductory to the other two, is devoted to the physical and chemical properties of the urine, and to the various alterations which it undergoes in health and disease. In the second part we have the "urinary diseases," which may be severally enumerated, as diabetes insipidus, diabetes mellitus, gravel, calculus, and chylous urine; while the third part treats of "the organic diseases of the kidney," and forms the largest division of the work.

In the first chapter, he presents us with a summary of the properties and composition of the urine, only so far, however, as such is necessary for practical utility, and gives a sufficiently full account of the physiological and pathological alterations in the excretion. The methods of examining the urine are next taken up, and the apparatus required described.

The physical properties of the urine are next presented in Chapter II., and in Chapter III. we have the inorganic deposits treated of, while the consideration of the organic deposits is treated of in Chapter IV.

In the second part of the work treating of urinary diseases, an analysis of all the facts hitherto published in reference to the nature and treatment of the two forms of diabetes, and of chylous urine, etc., is first presented. Then follows the discussion of gravel and calculus. The very full consideration of these latter affections forms the most attractive portion of the whole work. Not only have we a well digested history of these diseases, but the author gives us the results of some original observations in reference to their treatment. He has taken up the solvent treatment for calculi, and re-investigated it. The results of his observations are very gratifying as far as they go, and will tend not a little to popularize the particular kind of treatment which he recommends.

In order to give our readers an idea of the author's views with reference to the utility of the solvent plan of treatment, we must be permitted to follow him step by step in his investigation.

Uric acid being the most common form of calculus, his attention was naturally enough more particularly directed to it, although numerous experiments were instituted with a view of testing the solvent power of certain substances upon the calculi composed of other ingredients. The inquiry respecting uric acid, he says, "set out from two data. *First:* That solutions of alkaline carbonates exercise a solvent action on uric acid. *Second:* That the urine can be rendered alkaline from alkaline carbonates, by the administration of certain salts by the mouth." Starting from these data, a number of questions presented themselves for answer before proceeding further. These questions were: "1. Whether is carbonate of potash or carbonate of soda the better solvent for uric acid? 2. What is the best strength of solution to employ? 3. What is the effect of varying quantities of the solution on the results obtained?" The first question was answered in favor of the solution of the potash. In reference to the second query, the greatest solvent power was found to reside in solutions containing 40 to 60 grains of the carbonate to the imperial pint." The effect of the quantity of solution permitted to flow over the stone, "within the limits necessarily imposed by the capacity of the kidneys to eliminate fluids, proved to be comparatively unimportant." These questions being settled, others in turn came up. It was then found necessary to ascertain, 1. "The best way of alkalizing the urine, so as to impart to it an alkalescence corresponding to that of solutions of carbonate of potash of maximum solvent power," and 2d. "To examine the actual effect of alkalized urine passed over uric acid calculi, in a vial, at blood heat."

The use of the acetate or the citrate of potash in frequently repeated doses was found to be the most convenient method of alkalizing the urine. These salts were well borne by the stomach, and presented nearly equal powers. In order, however, to maintain the urine at a requisite degree of alkalescence, it was found necessary to administer to adults from 40 to 50 grains of one or the other salt in three or four ounces of water every three hours.

After detailing a few illustrative cases, he proceeds to enumerate those in which the solvent treatment is and is not applicable. These may be stated in brief, as follows: "1. The solvent treatment is inapplicable to all cases in which the urine is alkaline. 2. When the urine is acid the case may be regarded, *primâ facie*, as suitable to the solvent treatment."

But to the universal applicability of the treatment to the latter cases, "there are," he says, "numerous limitations. It the first place, all those cases are excluded in which it is known or strongly suspected that the stone is composed of oxalate of lime. 2. In those cases in which there is no indication of the nature of

the stone, we are left in doubt (the urine being acid) whether it is composed of oxalate of lime, or uric acid, or of alternating layers of these two substances. 3. Renal calculi, however, differ essentially in regard to this point from vesical calculi." The former are generally composed of a single substance, uric acid. The latter, if they have sojourned any considerable time in the bladder, are frequently compounded. In cases of renal calculi, he judiciously considers, in view of the preceding facts, that the patient should have the benefit of the doubt, as no other treatment than the alkaline is open to the choice of the practitioner. If by a chance the calculus should be one of oxalate of lime, the treatment of it does no good, but does not aggravate the case. 4. "In cases of vesical calculi," he continues, "the question stands differently. The solvent treatment comes here into competition with the mechanical methods of lithotomy and lithotrity, which long experience has stamped with success. It is no longer a question of the mere possibility of removing a calculus by means of solvents, but of doing it with less risk than by lithotomy and lithotrity." And further on he says, "Probably the most advantageous course to follow, if the stone be small, would be to try the solvent treatment for a limited period—for six weeks or two months—and if unsuccessful at the end of that time, to proceed without further delay to operation."

In summing up the cases to which the solvent treatment for vesical calculi is applicable, he necessarily makes the number small, and only promises success in those in which "the urine is acid; the stone not large; its composition known to be uric acid, or strongly suspected to be such."

The frankness with which he makes his statements in reference to the solvent treatment, shows him to be an unprejudiced observer, and one whose opinions and assertions are entitled to respect.

It is very much to be regretted that the range of applicability of the solvent treatment is not more extended, but still more so is it to be deplored that the rules which are to be observed in carrying out the treatment, even in this limited number of cases, are, by virtue of their stringency, so difficult of observance. He insists, for instance, that the urine must be maintained in a continuous state of alkalescence, and that this can only be effected by dosing the patient "at intervals of not less than three hours," during all the waking hours, and every time he may wake during the night to empty his bladder.

The only hope which this system of medication has for itself is in the desperation which drives the particular class of patients who suffer from calculi, to adopt any means that may promise them relief.

The salts recommended for administration as the best, are the acetate and citrate of potash. Of the former, the dose for an adult should be from 40 to 60 grains, dissolved in three or four ounces of water; and for children, the dose should range from 20 to 30 grains.

On page 257 he refers to the objections which have been urged against the alkaline treatment. The first objection, viz. the danger of the precipitation of the phosphates on the surface of the stone, he answers by affirming that if there be an ammoniacal decomposition of the urine the phosphates are deposited, whether alkaline medicines be given or not; but if the urine be alkaline solely from fixed alkali, not a *particle of phosphate deposit takes place.* The second objection, that the urine being naturally acid, any effort to induce a continuous alkalinity must have a deleterious effect upon the general health, he does away with, by a reference to the fact long recognised, that the secretion is nominally alkaline (from fixed alkali) for several hours daily after meals. And third, in regard to the impairment of the digestion which the administration of alkalies is said to induce, he proves that, so far as the acetates and citrates are concerned, there is no foundation for such a supposition.

The solvent treatment of vesical calculi holds out no prospect of any useful application; and our author leads us to the same conclusion with reference to oxalate of lime calculi, either in the bladder or beyond it.

As regards phosphatic calculi, there is, according to Dr. Roberts' assertions, strong foundation for a hope that the injection into the bladder of a weak acid solution may be attended with gratifying results. This, however, is the only course left us in the medical treatment of these calculi, inasmuch as acids cannot be made to pass through the kidneys save in insignificant proportions. The whole subject of calculous disease is very well treated, and the prominence which has been given to the medical treatment of this class of diseases is, it seems to us, warrantable under the circumstances. Although the treatment does not offer a very flattering promise of success, and is necessarily limited to a very small class of cases, it nevertheless sufficiently commends itself to the attention of the profession to induce a trial of the author's method.

The organic diseases of the kidney are severally considered in the third part of the work. Bright's disease receives some considerable attention, but is by no means treated of exhaustively. An excuse for this is to be found in the author's conviction, as stated in the preface, "that the present moment is not favorable for a lucid description of Bright's disease and its allies." The disease, however, is fully and intelligibly enough treated of to repay perusal.

The less frequent affections of the kidney claim rather extended notice, and this, considering the poverty of English literature upon the several subjects, is quite desirable. These diseases we cannot refer to more than by name. They are: hydronephrosis, cystic degeneration, cancerous and tuberculous affections, and parasitic diseases.

The last chapter, on the anomalies of position, form, and number of the kidneys, is made very interesting.

The attention which the study of urinary diseases is receiving, will insure for such a work as the one by Dr. Roberts, a welcome reception. We can confidently commend it to the profession as a reliable, interesting, and instructive work.

It is well printed, and the illustrations, of which there is a goodly number, are capitally executed.

DIARRHŒA AND CHOLERA: their Origin, Proximate Cause, and Cure, through the Agency of the Nervous System, by means of Ice; by JOHN CHAPMAN, M.D., M.R.C.P., etc. Reprinted, with additions, from the *Medical Times and Gazette* of July 29, 1865. Philadelphia: J. B. Lippincott & Co., 1866. 12mo. pp. 57.

The theory advanced in this pamphlet is, that the ultimate causes of diarrhœa and cholera produce their effects by inducing a hyperæmia of those nervous centres which preside over the bowels. These are notably the superior and inferior mesenteric plexuses. It has been demonstrated by Brown-Séquard and other physiologists, that the sympathetic regulates the contraction of bloodvessels, and that the vitality of the branches of this nerve depends upon the amount of blood in the ganglia. When the ganglia are hyperæmic, the filaments are stimulated, and cause contraction in the muscular coats of the bloodvessels. "The bloodvessels nourishing the tube, receive a larger supply of nervous influence from

the vaso-motor nerve centres than before, and hence, contracting more vigorously than natural, cut off to a proportionate extent the supply of blood to, and consequently the nourishment of the intestinal walls. The bowels thus lose their wonted robustness, and so become like a delicate lady with very little blood in her system, 'highly nervous,' and susceptible of being excited and thrown into excessive or convulsive activity by a stimulus which, in their healthy condition, would but slightly affect them."

Hence, considering it as established that there is this hyperæmic condition of the ganglia in cholera and diarrhœa, Dr. Chapman proposes to lessen the amount of blood in them by the application of ice along the spine. He says: "As a matter of fact, it is possible to lessen the amount of blood in nervous segments along the back, at a considerable distance above or below these particular segments over which ice is applied. It is indeed a physiological fact, so regular in its recurrence that it may be denominated a law, that when one nervous segment is rendered either anæmic or hyperæmic, the adjoining one will assume a like condition, though in a less degree, while those further removed will, in proportion to their nearness, also participate in the state impressed on the one first affected.

Of course it will not be assumed that the application of ice along the spine is a novel method: but it has been systematized by Dr. Chapman, and a reason based on physiological discoveries assigned for the treatment. Experiments already made in cases of epilepsy, seasickness, and some spinal affections, as well as in diarrhœa and cholera, have been satisfactory enough to warrant a continued trial of the vaso-motor therapeutics, although it has not as yet received the warm endorsement accorded to it by its author. Nor would the profession be willing at present to regard it as more than an adjuvant to other remedies in cholera.

Space and time forbid the present discussion of the views entertained by Dr. Chapman as to the cause and contagiousness of cholera, and these are also independent of the treatment advocated. Opium is quite warmly denounced in the conclusion of the work, but apparently without a thorough appreciation of the fact that this drug, in small doses, is an entirely different agent from the same medicine in larger ones.

This work will amply repay perusal, and suggest much interesting matter for reflection. It cannot, however, but be regretted that any obstacle to the general use of the ice-bag should be caused by the patenting of an apparatus which is regarded by its inventor as a great boon to the sick.

Progress of Medical Science.

Local Anæsthesia by Ether Spray.—Dr. Greenhalgh, of London, lately performed a Cæsarean section, assisted by Dr. B. W. Richardson, the inventor of local anæsthesia by means of ether spray, who used the anæsthetic apparatus. No pain was experienced by the patient during all the incisions, the child was delivered, but lived but a short time. The mother, however, did perfectly well, making a speedy and good recovery.

Ovariotomy has been performed twice after local insensibility was produced by the ether spray, once by Mr. Spencer Wells, of London, and once by Mr. Braddon, of Manchester.

The anæsthetic method has also been successfully used by Dr. Thorbun, of Manchester, for the operation of femoral hernia.—*London Medical Times and Gazette, April 7 and* 28, 1866.

We may add that Dr. Richardson's apparatus is in successful use in New York. We saw it used in two cases at Professor Gouley's clinic in the University Medical College. The cases were tumors of the scalp.

Vesico-Vaginal Fistula.—A writer in the *Hannover Zeitschrift für pratische Heilkunde*, who has been visiting the hospital at *Rostock*, and especially the division of it under the care of Professor *Simon*, in speaking of the skill and success of the latter in his operations for vesico-vaginal fistula, says:—"Simon has up to this time operated on about seventy vesico-vaginal fistulæ, a number which before and contemporaneous with him, no operator has reached (?), and has attained results which by far exceed those of the Frenchman *Jobert*, and the American *Sims*. Of forty-three fistulæ occurring in forty women operated upon by Simon up to 1862 and published, thirty-five were perfectly cured, five almost perfectly, only one remained unrelieved, and two died. The result of the last two and a half years, which comprehends more than thirty operations for fistula, and which will soon be published, shows a much more favorable experience, so that of all those operated upon, which now amount to more than seventy, only two remain unrelieved, while two have died. * * It is not too much to say that *Simon* restores continence of urine, in every defect of the vesico-vaginal wall, including the defects of the uterus and of the recto-vaginal wall, when only a piece of healthy urethra remains, which is from two and a half to three centimetres long."

Local Anæsthesia: A New Agent.—M. Delcominète, Professor at Nancy, claims that the power of sulphuret of carbon in producing local anæsthesia, is much greater than that of any other substance now used for this purpose. The refrigeration is more complete than with ether, and is obtained in less than a minute. The only objection to the general use of this compound is its intolerably offensive odor.

Trichina in American Pork.—The committee appointed by the Chicago Academy of Science, to examine into the facts concerning the supposed existence of trichina in our pork, have presented a very elaborate report upon the subject. Portions of muscle of 1,394 hogs, taken from the different-packing houses and butcher stalls of Chicago, were submitted to careful microscopical examinations, and twenty-eight trichinous specimens were found. The committee conclude that in the hogs brought to Chicago, one in fifty is affected with the disease in a greater or less degree, which indicates with little doubt the startling fact that trichiniasis in pork is even more common in this country than in Germany. But notwithstanding this fact, there is conceded to be very little danger of the disease spreading in this country, as Americans are in the habit of thoroughly cooking the pork before it is eaten. 160° Fahr. is a heat said to be sufficient to destroy the worms. "Again," says the committee, "by properly salting and smoking the meat for at least ten days, the trichina, should they exist, will certainly be killed." Simple desiccation of the meat, if continued for a period of sufficient length, will also kill them. *They will never be found alive* in old hams for instance (!). On the other hand, mere pickling appears to have very little effect upon these worms. They contend that a strict attention to the feeding of hogs and their confinement in pens where no animal food is accessible, is an infallible preventive against trichiniasis in them. They also endorse the European authorities in reference to the disease, that it is impossible to diagnosticate it from external appearances.

Novel Treatment for Gonorrhœa and Gleet.—Mr. Henry Thompson, at the University College Hospital, has lately been employing a new method of treatment for gonorrhœa and gleet. Believing that the imperfect action of injections depended upon the very short time that they are in contact with the mucous membrane, Mr. Thompson conceived the idea of applying the astringent in such a form as would enable it to remain for a much longer period in contact with the inflamed surface. Acting upon this conception, he caused "soluble bougies" to be made of cocoa butter, and of two or three inches in length. These bougies contained the drug that was to be applied to the part "They are cast in moulds, are perfectly firm and smooth, and may be used in any length; but that named has been deemed the best. A soluble bougie is equal in size to about No. 8 or 9 of the catheter scale, and may be introduced, having been previously oiled, by the patient himself, into the urethra, where the material gradually melts in the space of ten minutes. The patient is directed to slip one of these bougies into the passage before going to bed." Mr. T. has adopted the following method for retaining the bougie *in situ*. "A piece of adhesive plaster is cut nearly an inch wide and five inches long. A piece of Taylor's stout lint, of the same size, is rolled up into a little pad and laid on the centre of the plaster, which is warmed and applied along the lower surface of the dorsum of the penis, the prepuce, meanwhile, being fully retracted. A second strip of plaster, half the width of the first, is then put closely around the glans penis transversely. The bougies are made to contain either a quarter of a grain of nitrate of silver, a grain of tannin, two-thirds of a grain of acetate of lead, or ten grains of nitrate of bismuth, as astringents; while others are sedative also, and contain two grains of opium or two of belladonna. Other materials can of course be employed." By this method, Mr. Thompson is satisfied that the remedial agent will remain in contact with the diseased parts for several hours at a time; and is moreover necessarily squeezed into the lacunæ. Assuming the supposition that these lacunæ are harboring the discharge and escaping treatment at the same time, to be a correct one, this method would seem to be the only one to be implicitly relied upon. At all events, every surgeon must be ready to admit that Mr. Thompson's plan promises better results than can be obtained from transitory injections.—*Lancet.*

New Theory of Diabetes.—M. Mialhe, in a paper recently read before the Academy of Medicine at Paris upon diabetes, advances the opinion that "the disease is a chronic-nervous complaint involving all the nerves engaged in regulating the secretions."

Ligature of External Iliac Artery for Inguinal Aneurism—Recovery.—Mr. J. Wright Baker (*Lancet*) operated during the month of June, 1865, upon a male patient twenty-four years of age, for aneurism in the groin, caused by a scrofulous abscess in that locality, ulcerating its way into the coats of the artery above Poupart's ligament. The patient made a good recovery, the ligature coming away twenty days after the operation.

Elephantiasis of the Clitoris.—Dr. H. M. Lyman (*Chicago Medical Journal*, May, 1866) exhibited to the Chicago Medical Society a specimen of elephantiasis of the clitoris, removed by Dr. McClure from a patient at the almshouse. The patient was twenty-five years of age, the mother of several children, and had suffered from constitutional syphilis. The clitoris commenced to enlarge about three years previous to the time of its removal. It formed a pendulous bifid tumor, dangling between the thighs, and reaching half way down to the knees. Its surface was nodulated, and was ulcerated at several points, exuding a most offensive discharge. The tumor was easily removed by amputation, after the application of a whip-cord ligature around its pedicle. The stump cicatrized in eight days after the operation. Microscopical examination showed fibrous and connective tissue as the principal elements of the mass.

The Baneful Effects of Nicotine prevented.—M. Melsens has found that tobaccos, from various countries, contain nicotine in very different proportions. In tobacco from some parts of France (*e. g.* the department of the Lot) there is 7·96 per cent. of nicotine; whilst Havannah tobacco contains only 2 per cent. He proposes to smokers a way of preserving them from the effects of the alkaloid, and advises them to put into the tube of the pipe or cigar-holder a little ball of cotton, impregnated with citric and tannic acids. As the smoke passes through the cotton, it will deposit the nicotine therein, in the shape of tannate and citrate. M. Melsens has made very ingenious experiments, which go a very great way to prove that he is perfectly correct.—*Lancet.*

Ligature of the Primitive Iliac for Traumatic Aneurism.—Prof. Ralph N. Isham, of the Chicago Medical College, gives an account of a case (*Chicago Medical Journal*, April, 1866,) of wound of the anterior trunk of the internal iliac within the sacro-ischiatic notch, for which he ligated the primitive iliac. The patient, a private in the 35th Wisconsin Volunteers, aged twenty-five, received a bayonet wound of the right buttock through the ischiatic notch, March 18, 1864. He bled to the extent of sixteen or twenty ounces, immediately after which there occurred a great swelling of the abdomen and right buttock. He was kept under treatment at Camp Washburn two months, when the swelling decreased and he began to walk. On the 12th day of July he was reported fit for duty, but when he arrived at his regiment the tumor rapidly returned, with much pain, and he was hardly able to walk at all, even with a cane. The swelling continuing to increase he was, two days after, sent to the hospital at New Orleans, shortly after which, not improving, he was furloughed and sent North. While on the boat thither the surgeon opened the tumor, mistaking it for an abscess, but finding that it gave exit only to blood, closed the opening immediately. Oozing took place from the wound after this, and the patient arrived at Chicago in an exceedingly debilitated condition. On admission, he was suffering great pain, referred to the tumor and the right leg. He was very anæmic. On inspection of the parts, there was a hard, tense, red and glistening tumor occupying the right nates, extending from the crest of the ileum to the natal fold, and from the right border of the os sacrum to and over the anterior spinous process of the ileum. The cicatrix of the original wound was nearly in its centre, and beside it was the recent wound made by the surgeon, dilated to the size of half a dollar, and filled with clots of blood through which (October 2) arterial blood, for the first time since admission, escaped. A bruit was heard by applying the ear over the tumor, but no pulsation could be detected. On the occurrence of the hemorrhage (October 2), an injection of perchloride of iron into the sac was made. This temporarily arrested the bleeding. In the course of the next three or four days hemorrhage again occurred, notwithstanding repeated injections. It was then decided (October 7) to perform

the operation of tying the common iliac artery. The operation was performed, in the usual way, by Prof. Isham. The patient did well thereafter until the 10th, three days after the ligation, when an offensive discharge began to show itself from the wound in the sac—the result of a gangrenous condition of that part. The patient continued gradually to sink from this time, and died in the course of twenty-four hours after. The post-mortem examination showed a healthy condition of the artery—a well organized clot extending from ligature to aorta. The enormous sac was gangrenous, which condition was accounted for in its size, the pressure and irritation to which it was subjected during the long journey from New Orleans, and the breaking up with decomposition of the clots instead of fibrinous consolidation. Prof. Isham's case is the thirty-fifth recorded one of ligature of this artery. Of the whole number thus far reported, only seven have recovered. Fourteen of these thirty-five were operated upon for the arrest of hemorrhage in wounds, Prof. Isham's being one of this number, and only one recovered.

Nature and Disease.—In the course of a very able address on Tuesday (May 1), to the students of St. Mary's Hospital, at the summer distribution of prizes on the Relations of Physical Science to Medical Study, Prof. Huxley referred with a touch of keen humor to the old and trenchant satire which described Nature and Disease as two combatants fighting over the sick man, and the physician as a blind man who advanced with a club to settle the contest between them, and dealt heavy blows which might sometimes fell the one and sometimes the other, as chance directed. If this ever had been true, he said that it was assuredly not applicable to the practice of medicine in this day. But he ventured to change the metaphor into a form which made it better adapted to the present state of medical practice. The physician, he said, could no longer be typified as the blind man—he must be shown as a man keen-sighted, wary, and well armed; but the combatants were fighting in the twilight—a twilight so obscure, so variable and so deceptive, that he was fain to hold his hand to refrain as much as possible from striking, lest he deal a mischievous blow where he least intended, and rather to play the part of the "judicious bottle-holder"—to stand by to help exhausted nature, and assist in bringing her "up to time." No doubt Prof. Huxley had in mind the brandy-bottle, which is unquestionably one important resource of the restorative and expectant school of medicine.—*Lancet.*

Symptoms of Trichiniasis.—Dr. Herman Keifer, of Detroit, in a well written article on the Trichina Spiralis, in the *Detroit Review* of Medicine and Pharmacy, for May, 1866, in referring to the sufferings of patients with trichiniasis, quotes the following graphic description from Dr. Kraatz —"Imagine in a small room, twenty or thirty men lying sick; notwithstanding that number, the silence of the grave existing, for neither do the patients complain nor move themselves; there they lie, as living corpses, and with widely opened eyes those pale faces, without expression, gaze at us. These miserable creatures not only live, but have the full use of their faculties, without being able to speak, from paralysis of the larynx. They suffer indescribable pains in all their limbs, but must, of necessity, lie motionless, as every movement of a muscle increases their agony. They long for water, and suffer from hunger, but every swallow of liquid or morsel of food is embittered by the increased suffering the motion of mastication or deglutition involves. So they seek oblivion and ease in sleep; but even this sweet restorer is denied them; many of the patients had not shut their eyes for a fortnight. What were the miseries of Tantalus compared to these?"

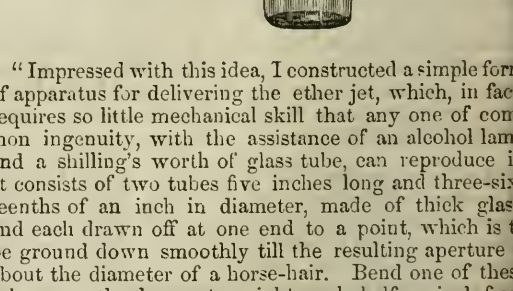
Duration of the Electric Spark.—Professor Wheatstone has decided that the duration of the electric spark does not exceed the twenty-five-thousandth part of a second. A cannon ball would appear stationary in its flight if illuminated by the spark, and the wing of an insect that moves ten thousand times a second would seem at rest.

New Instruments.

A SIMPLE NEBULIZER.

Dr. Jos. G. Richardson, of Union Springs, Cayuga Co., N. Y., thus remarks upon a simple form of nebulizer, a wood-cut of which we give below:

"The general employment of subcutaneous injections, invaluable as they are for the relief of certain cases of neuralgia, and some other agonizing affections, has been heretofore so greatly obstructed by the fact that a majority of patients, especially females, entertain an invincible dread of the pain inflicted by making the necessary puncture; that on reading the description of Dr. B. W. Richardson's method for producing local anæsthesia by a jet of nebulized ether, it appeared to me that his ingenious invention was doubly useful as affording a means of entirely obviating this difficulty, and of rendering the administration of opiates, etc., by the hypodermic mode as free from discomfort, and certainly less disagreeable than by any other avenue for their introduction into the system."



"Impressed with this idea, I constructed a simple form of apparatus for delivering the ether jet, which, in fact, requires so little mechanical skill that any one of common ingenuity, with the assistance of an alcohol lamp and a shilling's worth of glass tube, can reproduce it. It consists of two tubes five inches long and three-sixteenths of an inch in diameter, made of thick glass, and each drawn off at one end to a point, which is to be ground down smoothly till the resulting aperture is about the diameter of a horse-hair. Bend one of these tubes over the lamp at a right-angle half an inch from its small extremity, and again at its middle in an opposite direction to the same extent; then attach both tubes to a grooved cork so that the capillary opening of the bent or lower shall be opposite to the central perforation of the upper straight one, and having adjusted these so that they are found to work properly, cement them firmly in that position by the aid of sealing-wax. The lower end of the first tube dips to the bottom of a half-ounce bottle filled with ether, and suspended by an elastic cord from the horizontal tube, whose larger extremity is attached by a perforated cork to the nozz

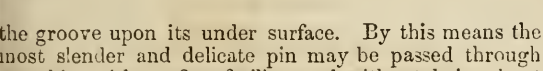
zle of a common rubber syringe, which forms an efficient substitute for the elastic ball of the regular apparatus. This instrument performs better if the lower termination of the first tube is supplied with a minute valve, perhaps most conveniently arranged by dropping a No. 6 shot into it, drawing off to a point and then grinding this down until its calibre is nearly, but not quite, sufficient to allow the little bullet to fall out.

"After repeated experiments with the apparatus upon my own arm and my friend Dr. Pary's, the point selected being the usual one below the deltoid's insertion, I can state that the application of this jet (interrupted as it of course is) for fifteen seconds decidedly diminished the twinge of making the hypodermic puncture; when continued for thirty seconds, the tissues made but slight complaint of the needle's passage; and after a nebulization lasting forty-five seconds, no pain whatever was perceptible during the operation.

PROF. A. C. POST'S NEEDLE DIRECTOR.

This instrument is designed to facilitate the introduction of insect pins for sutures in wounds of the face, and of other parts where it is important to secure an accurate adaptation of the edges of the wound.

It consists of a needle two inches and a quarter in length, of a diameter corresponding with that of a very large darning-needle, straight except at the point, where it is slightly curved to the extent of a quarter of an inch, and having a small flat handle at its proximal extremity. The curved portion of the needle is flattened, and has cutting edges. Throughout the greater part of its length the needle has a groove on the side corresponding with the convexity of its curve. In using the instrument, the needle is passed through the edges of the wound in the position which is to be occupied by the pin, and the pin is then slipped along



the groove upon its under surface. By this means the most slender and delicate pin may be passed through the skin with perfect facility, and without being bent out of shape. As soon as the pin is introduced, the needle is withdrawn, and the pin is secured by a thread in the form of the figure of 8, and the point of the pin is removed by cutting-pliers. The description will be rendered more intelligible by the above wood-cut.

Death from Chloroform.—An instance of this has lately occurred in the southern part of the city of Philadelphia. It appears from the evidence at the inquest, that the chloroform was given at the request of the patient to produce anæsthesia during the extraction of a tooth, she stating that she had previously taken it without injurious effects. In a minute or two after inhaling the vapor she turned deadly pale, went into convulsions, and soon died. The chloroform seems to have been pure, as the dentist testified that he had given a larger inhalation of the same to a child on the same day. On *post-mortem* examination all the organs were found perfectly healthy.—*Medical News and Library.*

Correspondence.

"THE CHOLERA CAMPAIGN."

To the Editor of the Medical Record.

Sir—In view of the possible reappearance of the cholera in this country during the coming summer, anything bearing on the history of the disease at the time of its previous visitations becomes a matter of general interest. I therefore venture to send you an account of the disease as it appeared on the U. S. transport steamer *Henry Clay*, on Lake Erie, in the summer of 1832. It is taken from the journal of a distinguished officer of the army—at that time a First-Lieutenant in the Fourth U. S. Artillery—who was on board the steamer. It is interesting, as being among the first of the cases that ever occurred in this country.

The troops on board had left New York on the 20th of June four days before the breaking out of the disease in that city; and although it had appeared in Montreal on the 8th of that month, it had not extended southward, and there were no cases in Buffalo as early as the 2d of July, when the troops left there. The disease broke out in the steamer when in the middle of Lake Erie, opposite the town of Erie, in Pennsylvania. The command on board numbered fourteen officers and about four hundred men. The first case that occurred is thus described by the officer writing the journal. He says: "He had violent spasms of the arms and legs; his eyes had a peculiar glassy and fixed appearance; his features were sunken, and he appeared to be a great sufferer." All the early cases proved fatal; in fact, none recovered until they were removed from the steamer to a clean airy camp, near Fort Gratiot, in Michigan. So fatal was the disease, that the expedition was entirely broken up, and obliged to return; and it has ever since been designated in the army as the "*Cholera Campaign.*" In every case it was noted that men who indulged freely in intoxicating liquors to drown their fear, took the disease and died.

The account which follows was written by a non-professional man, in his private journal, and does not consequently contain those items which would be more interesting to a physician. On another page of the journal he makes, however, a shrewd suggestion in regard to the origin of the disease. "It was long a matter of astonishment to me," he remarks, "how the disease could possibly have got amongst us—but my doubts on that subject are at an end. I am fully convinced that the disease is carried through the air, and that in going from Buffalo to Detroit we passed through a column of the infected air." It would be interesting in this connexion to know on what day the disease made its appearance at Erie and other towns in northern Pennsylvania.

Yours, &c.,

Harvey E. Brown,
Assistant-Surgeon U. S. Army.

Extracts from the Journal of an Army Officer, written during the Prevalence of the Cholera on the Steamer Henry Clay, on Lake Erie, in July, 1832.

"In 1832, through the machinations of the celebrated Indian Chief, Black Hawk, the Sacs and Fox tribes of Indians became hostile to the whites, and troops were ordered into their country to suppress them. General Scott had the chief command. A large portion of the Fourth Artillery was ordered on this duty, and with hardly a day's notice I was directed to proceed to Fort Columbus, assume command of Company H, and pro-

ceed with it to the Mississippi River (Black Rock) near the Lakes and Chicago. The companies of our regiment were placed under the command of Major M. M. Payne, a good and efficient officer. Caring for my wife and our little ones in our humble little cottage, I proceeded with our command up the North River and on the Erie Canal. At this time, although no case of cholera had been in the States, yet as it had reached Canada, great apprehensions prevailed. We were at almost every town subject to quarantine inspection, but not one individual of us had ever seen a case of cholera. We therefore arrived at Buffalo, and embarked from thence, on the 3d of July, on board the steamer *Henry Clay*, our command consisting of, I think, four companies of the Fourth Artillery, and some two hundred recruits, and about ten or fifteen young gentlemen just graduated at West Point, who were going to flesh their maiden swords against the Indians. We proceeded without incident until we had left Erie on the 4th of July; and in the evening, while the younger officers were gaily celebrating the day, and the others sitting or lounging listlessly around, a man came and reported that one of the men on deck was ill, and very strangely attacked (let it be remembered that not one of our command had ever seen the Asiatic cholera, or been where it prevailed). We went on deck, and found him to be very sick, with a strange expression of the eyes and features, with which we were afterwards but too familiar. The doctor pronounced it cholera; the man died before we reached Detroit, as did another. Arriving there, we were visited by the Health Officers, and the opinion of our surgeon confirmed. An additional surgeon was ordered on board; poor fellow, he was so alarmed that previously to coming he made his will. We landed some citizen passengers who were on the boat (several of whom, as we afterwards learned, died, and they spread the disease far and wide throughout Michigan), and were ordered to proceed up the river three or four miles to Hog Island, and there await further orders. By this time several more cases occurred. That evening General Scott passed us on his way to Chicago, hailed and ordered us to follow him to that post. We did so, but before we had reached Fort Gratiot, at the month of the river, and on the borders of Lake Michigan, our decks were literally covered with the dead and dying, and so many of the crew were either sick or dead that the vessel could not proceed, and we had from necessity to land. We did so, and encamped on a point of land about a mile from the fort, and immediately put all hands capable of working to erecting tents and huts for the sick. Before we had finished, a heavy rain came on which made the disease much more virulent; the young graduates were permitted to leave, and the recruits, almost to a man, deserted. We procured a large barn for a hospital, which was soon filled. Doctor Everett was taken sick and died; and Lieut. Clay, a gallant young officer, also fell a victim, and our poor soldiers died off by the dozen. In one or more instances I was awakened before reveillé to bury men who were at tattoo roll-call, so rapid was the progress of the disease. We had a young surgeon Ker, full of talent and zeal, who devoted himself night and day to the sick, and it is wonderful how he endured even the want of sleep and physical exhaustion to which he was so long exposed. A young sergeant, named Lenison, also is worthy of being remembered; he volunteered as steward of the hospital, and continued assiduously to nurse and attend the sick and dying the whole time, and he never had the disease.

"To give some faint idea of the awfulness of the disease, and of the panic that seized a portion of our command, I will relate a circumstance that occurred to me. I was directed to send two men as nurses to the hospital; I gave the necessary orders to have the men detailed, which being done, they came to me and begged that I must not send them to the hospital, as it would be their death. I told them I was very sorry, but that it was necessary the sick should be nursed; that they were the first on the roster for duty, and that they must go. They showed great reluctance, and finally so far refused to go that I had to take my sword and actually drive them to the hospital. That same night both deserted. The next day both returned with horror expressed in their features, and begged I would pardon them, stating that they would a thousand times rather go to the hospital than witness the horrid scenes of the road they had passed over. They said the road was literally strewed with the dead and dying men who had deserted to escape the disease, and that they saw hogs eating not only dead bodies, but in one or two instances those that had yet life in them.

A few days after our landing, the troops evacuated the fort, and we moved in. Several of our officers were sick, and two or three, to their shame be it said, so frightened as to report sick and to remain in their quarters during the whole time of the raging of the disease. This made duty come very hard on the others, and more particularly as *all* were more or less under the influence of the disease and weakened in strength, but kept up by excitement and a sense of duty. I have seen six or eight dead bodies lying at one time at the hospital waiting for burial. A singular fact in connexion with the disease is, that every baker and every man working in the bakehouse had the disease, and several of them died. Colonel Twiggs and Major Payne (first and second in command) both had the disease, but both recovered. The disease lasted two or three weeks, during which time we lost by death and desertion two-thirds of our command. I lost one-third of my company by death. I was, in addition to my duties as commander of a company, Quartermaster and Assistant Commissary of Subsistence, and was so busy from morning till night that I had no time to think about getting sick; but I had, as all had, the premonitory symptoms—constant diarrhœa and pains in the joints. I resorted freely to the bath, and have no doubt but it was beneficial."

CHOLERA IN 1832.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR—Your correspondent "E" asks: "Can any of the brethren familiar with the epidemic of 1832, testify to what extent physicians abandoned their posts, and fled to the country?" as stated in the reminiscences of a venerable clergyman.

Having been one of the physicians of the City Dispensary during the prevalence of the epidemic of that year, I may state unhesitatingly that the assertion above quoted is a slander upon our noble profession. With the exception of the family physician of the venerable man, I cannot call to mind any other physician who abandoned his post and fled to the country. Dr. A. W. Ives (the physician alluded to), was for a short time in charge of the Cholera Hospital in the Park, but being in declining health, and of a very nervous temperament, he was obliged to resign his office, and retire to the country to recruit his strength. He died of malignant chronic disease in 1836. I have not the official records of that epidemic for reference, but I well know that several medical men fell victims to their devotion in the cause of suffering humanity.

The reverend gentleman probably forgets, that on the

first appearance of the epidemic cholera in 1849 he embarked for Europe, and was absent from his charge about two months, his church being closed, and his flock scattered. During the first epidemic, he remained at his post, like a good shepherd, but during the second who cared for the sheep?

FIAT JUSTITIA.

Obituary.

PROF. JOSEPH MATHER SMITH, M.D.

PROF. OF MATERIA MEDICA AND CLINICAL MEDICINE IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

THIS eminent gentleman, whose lamented decease we are called upon to announce, was born at New Rochelle, Westchester County, N. Y., March 14, 1789. His father, Dr. Matson Smith, was a distinguished physician of that place, and his mother, a Miss Mather, one of a New England family long distinguished for preëminence in medicine and divinity.

At the age of fifteen, Dr. Smith removed to New York, and engaged in mercantile pursuits, but having no taste for such occupations, returned to New Rochelle in 1808, and commenced the study of medicine in his father's office. He attended the Medical Lectures in Columbia College during the session of 1809 and 1810; was licensed to practise Physic and Surgery in May, 1811, by the Medical Society of Westchester County, reading before the Censors, at his examination, a dissertation on "Respiration," and in the same year (1811), settled in this city as a practitioner of medicine in partnership with the late Dr. William Baldwin, an association which continued for several years.

In 1815 he graduated at the College of Physicians and Surgeons, New York. The subject of his thesis was "Phlegmasia Dolens." About the same time he united with several young contemporaries, Mott, De Puy, Bliss, and others, in forming the New York Medico-Physiological Society, and served on the Committee of Publication. Under his supervision, the first volume of its Transactions was published in 1817, to which he contributed a paper on the "Efficacy of Emetics in Spasmodic Diseases, with an Inquiry into the final cause of sympathetic vomiting," which at the time attracted much attention, and is still considered to be ingenious and original. In the same work he published also a case of "Poisoning by Opium, successfully treated by Flagellation." In June, 1820, he was appointed Visiting Physician to the New York State Prison, situated in Greenwich street, in association with Professor Hammersley, which situation he retained till April, 1824. In 1821, he was elected a Fellow of the College of Physicians and Surgeons, New York.

The year 1824 may be considered as the turn in the tide of his fortunes. In this year appeared his celebrated "Elements of the Etiology and Philosophy of Epidemics;" a work so learned and so logical as to have attracted everywhere the most profound attention, and stamped its author as a man of no ordinary thought and ability; which has been pronounced by a late English writer to have been "fifty years in advance of the medical literature of the day, on its subject," and has not even yet, we believe, been surpassed or superseded. In the *Medico-Chirurgical Review* for July, 1825, it is pronounced "ingenious and philosophical, characterized not only by great talent and force of argument, but by candor and good faith," and as "doing great honor to trans-Atlantic medicine." We find, by reference to a "report on the Medical Topography and Epidemics of the State of New York," submitted to the American Medical Association in 1860, and published in their Transactions, that to the views, terminology, classification, and etiology of epidemics adopted in his "Elements," Dr. Smith still adhered, and we regret that our limited space does not enable us to do more ample justice to this truly classical work.

It was undoubtedly owing to the evidences of great ability manifested in, and the reputation achieved by this publication, that Dr. Smith owed his unsolicited appointment, in 1826, to the chair of Theory and Practice of Physic, in the College of Physicians and Surgeons of this city, as the successor of the great Dr. David Hosack; in which institution, as we all know, he continued a Professor until his death.

The zeal, ability, punctuality, and fidelity with which he performed the duties of a teacher, even to the very last period of his life, when exhaustion scarcely permitted him to struggle on to the completion of his course, are beautifully characteristic of that ardent devotion to duty and rectitude of principle which characterized his long and useful career.

In 1829, Dr. Smith was appointed attending Physician to the New York Hospital. This position he continued to hold with advantage to the interests of the institution and its patients, and most acceptably to the students who congregated there for clinical instruction, until his decease.

During the cholera epidemic in this city in the year 1849, Dr. Smith served with Drs. J. B. Beck and Samuel W. Moore, as a member of the Sanitary Committee, these three constituting the "Medical Council." Three abler and fitter men could not have been selected; and we find that their duties were fulfilled with great and conscientious zeal and ability; their measures prompt and judicious; their public addresses prudent and practical; their advice relating to the prophylaxis of the disease, such as could not fail, if properly attended to, to be immensely beneficial. Their labors were arduous, but they found their reward in the assurance of their great public utility, the satisfaction of their own consciences, and the approbation of their fellow-citizens.

In 1850, Dr. Smith delivered an oration on the occasion of the fourth anniversary of the establishment of the New York Academy of Medicine. The subject was rather an unusual one, the "mental phenomena manifested in the lives and deaths of military men," but it was marked with his usual extent of research, felicity of illustration, logical acumen, and elegance of style and diction.

In 1854, he was unanimously elected President of the N. Y. Academy of Medicine; the duties of which situation he filled with wonted urbanity and acceptability, for the prescribed period of one year.

In 1853 and 1854, he assumed the professorial duties in the college, of his friend Dr. J. B. Beck, and during the fatal illness of the latter, conjointly with those of his own chair, delivered the lectures on the Materia Medica. In 1855, he assumed the exclusive duties of this chair; those of Practice and Physiology being divided between Drs. Alonzo Clark and Jno. C. Dalton. In this capacity he continued until the period of his death, which occurred some six or seven weeks after the completion of his course. In 1864, he was appointed President of the Council of Hygiene of the Citizens' Association of N. Y.; to whose efforts is due the establishment of the present Board of Health, and the active, ably devised, and we trust, efficient improvement in the sanitary condition of the city which is so greatly needed, and in view of the pestilence with which we are hourly menaced, so indispensable to the public health and welfare. To the duties of this office he gave his most earnest attention and highest abilities.

They corresponded perfectly with his tastes and studies, and his opinions upon all subjects of Hygiene were necessarily regarded with the highest respect and deference.

We now approach the end of this modest, but active, useful, and brilliant career; one which had elevated Dr. S. to the highest eminence in the estimation both of his professional brethren and of the public. The mental and bodily wear and tear of so long and busy a life, aided by the increasing infirmities of age, at length overcame a constitution naturally robust, and fortified by temperance and abstinence. About a month before the commencement of his last course of lectures, his stomach lost both its tone and its retentiveness; although he still continued to attend to his professional duties, private and hospital; but, for almost the first time in forty years, he missed the delivery of the first twelve lectures of his course. In November, afterwards, he resumed and completed them; though often obliged from debility to seek in repose, upon his return from the college, the strength needed for the fulfillment of the duties of the morrow. He could not bear that the students should be deprived of their due share of instruction; and, like the pelican in the fable, he may be said to have nourished his young with the life-blood from his own breast. Such sacrifices of self to duty are as rare as they are beautiful; but such was the man.

For some weeks afterwards he was very ill; but rallied, took a little out-door carriage exercise, and seemed improving. But the amendment was illusory. The flame leaped up in the socket with a sudden warning blaze, to be the sooner extinguished. On Thursday, April 19, at 9 A.M., while sitting up in his bed, and taking nourishment, the "golden bowl was broken and the silver cords were loosened." Hemiplegia gently seized his entire left side. His consciousness continued until evening; and his last intelligible accents conveyed a blessing to his devoted and dutiful son. He lay for two days in a quiet coma, without stertor, grimace, or convulsions; until on Sunday, 22d, at 7.20 A.M., nature and his labors both exhausted, his beautiful and gentle life ended in a death as gentle and as beautiful.

> "They thought him dying when he slept,
> And sleeping when he died."

His funeral services took place on the Tuesday following, April 24, in the church of his pastor, the Rev. Dr. Adams, who justly eulogized him as a man without guile, in the midst of a large concourse of his sorrowing brethren and friends. He was in the 77th year of his age. His remains were taken to his native place, New Rochelle, and interred, with others of his kindred, in the family vault at that place.

Thus died, honored and respected, one of the best and ablest men whom the profession in this country has produced. At a proper time, at proper length, and in fitting terms, a suitable eulogy will no doubt be made of his merits. For the present, let the love, respect, and confidence of all who knew him furnish his epitaph: love for his suavity, respect for his virtues, confidence in his learning, his judgment, and his skill. If any monument be needed, the pages of American medical literature will supply one, *ære perennius*. This is the humble tribute to his memory of a pupil and a friend.

We append a list of his principal writings other than those to which we have incidentally alluded:—

1. Case of Stricture of Pelvis, with Autopsy. By Prof. Mott. (*N. Y. Med. Register.*)
2. Case of Dyspepsia, with Constipation. (*Med. Repos.*)
3. Review of Sir G. Blane's "Medical Logic." (*Med. Repos.*)
4. Review of Gregory's Practice of Medicine. (*N. Y. Med. & Phys. Jour.*, 1827, Vol. 1.)
5. Review of Bechet's Pathological Anatomy, and Martinet's Manual of Pathology. (*N. Y. Med. & Phys. Jour.*) Dr. S. was, for one year, 1828, associated in the conduct of this journal.
6. Biographical Memoir of Dr. Dupuy. (*Same work.*)
7. Introductory Lecture at College, 1831, on the Epidemic Cholera of Asia and Europe.
8. Ditto, 1839. "Comparative View of the State of Medicine in 1733 and 1833."
9. Ditto, in 1846, on the "Public Duties of Medical Men:"
10. Ditto, in 1848. "Influence of Disease on the Intellectual and Moral Powers."
11. An Address delivered on the Occasion of the Inauguration of the New South Building of the N. Y. Hospital. April 18, 1855.
12. Report on Practical Medicine. (*Am. Med. Trans.* Vol. 1.)
13. Report on Public Hygiene. (*Trans. Am. Med. Assoc.*, V. 3.)
14. Sketch of the Professional Life and Character of Matson Smith, M.D., of New Rochelle.
15. Notice of Louis on the Yellow Fever of Gibraltar, 1828. (*N. Y. Jour. Med.*)
16. Puerperal Fever: its Causes and Mode of Propagation. Read before the N. Y. Academy of Medicine. Published in the *N. Y. Jour. of Med.*, and for private circulation. This learned, logical, and exhaustive essay, which is an almost unequalled authority on the subject and causes of this interesting and important disease, was widely noticed and most favorably commented on abroad.

The report on the Medical Topography Association, 1860, of the Epidemics of New York (*Trans. Am. Med.*) is a volume of 200 pages, compiled with immense learning, labor, and research, and has been greeted with the most lavish eulogium by the reviewers and the profession, from whom many letters were received in terms of the highest commendation. In the meteorological section of the work, to which he gave especial labor and attention, Dr. S. introduced several scientific, new, and appropriate terms, and illustrated the climate of the State in an ingenious and original manner by maps, plates, and tables.

Such are a few of the arduous and ably accomplished labors of a long, literary, and industrious life, on which rest Dr. Smith's claims to the respect of his medical brethren and to the favorable verdict of posterity.

P.S.—A portrait of Dr. Smith, said to be a very life-like resemblance, by Baker, was taken for and presented by several of his older office students to the Governors of the New York Hospital, and by them placed among the portraits of those who had faithfully served the institution—an honor which no one, surely, has more richly deserved.

LEMAIRE ZABRISKIE, M.D.

Abstulit atra dies et funere mersit acerbo.
Virg. Æneid, Lib. vi, 429.

LEMAIRE ZABRISKIE, M.D., the elder son of Christian Zabriskie, Jr., was born in New York city February 3d, 1844. After having passed the usual novitiate in one of the public schools of the city, he entered, July 16th, 1858, the College of the City of New York, then known as the "Free Academy." Here he at once attained the highest position in his class, and in the Junior year, won

the gold medal for "General Proficiency," an honor gained by but one other in the history of the Institution.

Besides this, he also received certificates showing him to be the ranking student in "English Literature," "Logic," and "Astronomy." In his Senior year, there were awarded him the gold medal for "greatest proficiency in mathematics," and certificates of similar import in the departments of "Latin" and "Moral Philosophy." He closed his scholastic career July, 1863, with still another coveted prize, the Valedictory Address at Commencement. He now entered with zeal upon the study of his chosen profession, and by a devotion to details soon achieved among his fellows a reputation for accurate and thorough knowledge which suffered not at all in the searching examinations to which, for two years, he was subjected in the office of Prof. James R. Wood, his medical preceptor. After the reception of his degree, Feb. 24, 1866, from the Bellevue Hospital Medical College, he successfully passed the prescribed examination which was to constitute him an *interne* of the hospital. But in the course of his duties, which he never neglected but always exceeded, he fell at his post March 29th, 1866, a martyr to Typhoid fever, loved, admired, and mourned by all.

PROF. HENRY G. COX, M.D.

Dr. Henry George Cox, a native of the island of Bermuda, where he received his Baccalaureate degree from the Devonshire College in 1838, and held several local positions of importance, emigrated to this city in his twenty-third year. Soon after his graduation in 1849 from the College of Physicians and Surgeons, he was appointed assistant physician to the Quarantine Hospital, Staten Island, and served as such until 1850. He was then called to fill the position of Physician to the New York State Emigrant Hospital, which he, in turn, resigned in 1855, in order to assume the Chair of the Theory and Practice of Medicine in the New York Medical College, the duties of which he discharged until the suspension of that institution in 1864. He was also a physician to the Nursery and Child's Hospital from 1854 to 1859. He had scarcely entered upon his position of Consulting Physician to the Emigrants' Hospital, to which by way of recognition for past services the Commissioners of Emigration had recently appointed him, before he was seized with a paralysis, which ended his existence, May 29, after an illness of three weeks.

He was widely known as a skilful, conscientious practitioner, and universally esteemed for his kindly disposition.

New Publications.

Books and Pamphlets received.

Why Not? A Book for every Woman. The Prize Essay, to which the American Medical Association awarded the Gold Medal for 1865, by Horatio R. Storer, M.D., of Boston. Issued for general circulation by order of the American Medical Association. Boston: Lee & Shepard, 1866.

Food and its Digestion; read before the Albany Institute, Feb. 27, 1865, by Howard Townsend, M.D., Prof. of Physiology and Materia Medica, Albany Medical College.

Instruction in the Preparation, Administration, and Properties of Nitrous Oxide, etc., by Geo. T. Barker, D.D.S., Prof. of the Principles of Dental Surgery and Therapeutics in the Pennsylvania College of Dental Surgery. Philadelphia: Rubencame & Stockton, 1866.

Advice upon Epidemic Cholera, by Edward R. Squibb, M.D., Brooklyn, N. Y.: N. Y. Printing Company, 81, 83, and 85 Centre Street, 1866.

On Idiocy, by E. Seguin, M.D. N. Y.: W. Wood & Co., 1866.

Medical News.

Appointments.

New York Hospital.—Drs. Governeur M. Smith and C. E. Hackley have been appointed Attending Physicians.

Philadelphia Hospital.—Dr. Jas. De Benneville has been appointed Attending Physician.

Bellevue Hospital.—Dr. H. B. Sands, Attending Surgeon, vice Dr. W. Parker, resigned.

Quarantine Hospitals for New York.—The Board of Health, with the aid of the General Government, took possession on the 6th inst., of the State lands at Seguin's Point, Staten Island, for Cholera Hospitals. The passengers on board the Cholera Ships will be transferred to this place as soon as it is cleansed, and the old buildings which are on it made fit for their reception.

PROGRESS OF THE CHOLERA.

England.—Owing to the appearance of the cholera at Rotterdam, and the progress made by the disease even at this early season, the Committee of the Privy Council have issued a circular to the local authorities at the different outports in the United Kingdom, urging them to take precautions against the introduction of cholera, and to be prepared for its coming.

Cases have occurred at Bristol, Hull, and Liverpool—the name of Dr. Ross, of the Helvetia, appears upon the mortality-lists of the last-mentioned city. The *London Times*, in a leader of the 2d ultimo, pronounced it "less of an exotic pestilence, and more of an ordinary epidemic," an expression probably of some value as indicating the mildness of the type and the absence of any general panic. We may also state that Earl Granville declared in the House of Lords on the 15th ult. that a thorough system of quarantine could not be carried out in England, and that the government had given the local authorities all the powers the law empowered them to give.

The West Indies.—Two cases of sporadic cholera, which did not, however, result fatally, occurred at Havana during the latter part of May, but the general health of the island of Cuba was reported satisfactory. The cholera, upon which previous accounts agreed as having abated at Guadaloupe, has again broken out at Pointe à Pètre. The sanitary condition of the other islands of this group is, as far as known, good.

Detroit, Mich.—According to the *Free Press* of the 29th ult., three deaths occurred among the children of an emigrant party which arrived in the city by way of the Great Western Railway. One of the children died on board the train, and the other two at the dépot. No autopsies were held, and we are merely informed that the family was extremely filthy, and had just come from the ship which brought them over.

Quarantine, N.Y.—Of the sick belonging to the Virginia, the last death by cholera occurred on the 23d ult., since which time there had been no admissions, from the 7th ult. to the 28th ult., when all the cases were convalescent. All the steerage passengers of the Virginia who had not been attacked with the disease were, accordingly, permitted to come to the city on the 30th ult.

The British steamship Union, Captain Palmer, from Liverpool, arrived May 29th, after a passage of sixteen days and a half. She left port May 12th, with 434 passengers, and the first case occurred on the 18th in the person of a Dane, who died twelve hours after the attack. Thirty-three died on the passage, mostly of cholera, and thirty-four were sick upon arrival.

The steamer Union was joined May 30th by the steamship Peruvian, from Liverpool, with seven hundred and fifty-eight passengers, of which number twenty-eight were sick with the pestilence. Thirty-five deaths had occurred during the voyage, and many of those who were removed upon their arrival at this port on board the hospital ship were in a dying condition.

A revenue cutter has been, or will be, stationed in the lower bay for the protection of the quarantine vessels, and to prevent the passengers detained there from escaping to the shore.

New York City.—Dr. Harris reports the following: "The case in the Sixth avenue was that of a woman who lived over a stable in a tenant-house where the sinks were offensive, and causes of cholera abundant. She was seized with the ordinary symptoms of cholera on Wednesday, began to recover on Thursday evening, and is quite well this morning (June 1st)."

On board the Steamship Helvetia.—The officers of the steamship City of Paris, recently from Liverpool, report that the cholera broke out on the steamship Helvetia while that vessel was between Liverpool and Queenstown, and that the Helvetia had returned to Liverpool in consequence thereof. The Helvetia belongs to the National Steam Navigation Company's line, and is said to have had a large number of passengers on board. She left Liverpool on the 27th of April for this port via Queenstown, and had scarcely got under way, when the disease made its appearance.

The Cholera Epidemic in the City of Altenburg,* Germany, in 1865.—The city has 1,359 houses, occupied by 4,112 different families, and contains 17,966 inhabitants. The city, before the outbreak of the cholera, was in an unusually healthy condition. Still, a greater part of the middle class lived almost entirely on bread and vegetables, rank coffee and beer; only among the better classes was meat regularly eaten. The first case of cholera was the daughter of a lady who came from Odessa, leaving the latter place on the 16th of August, and reaching Altenburg on the 24th, having travelled nine days and nine nights without cessation. On the 27th of August, at noon, a physician was called on account of diarrhœa in the child, which had existed at the time it left Odessa. The mother was well. There was at this time no epidemic in Odessa; the passengers on the vessel on which the two had come from that port, were also well. Still she (the vessel) had passed by certain places on the Turkish border where the cholera was raging. On the same day (August 27th), at nine P.M., the lady became sick also. She had all the symptoms of Asiatic cholera when the doctor saw her early on the following morning, and on August 29th, at half-past two A.M., she died. In the same house, on the 29th of August, at eight P.M., the sister-in-law of the lady was attacked with cholera and died on August 30th, at half-past eleven P.M. This house formed the first centre of infection, from which the disease could be shown to have extended. The epidemic lasted from August 28th to November 18th. Of the one hundred and eighty cases which occurred, one hundred and eight were fatal—that is, 60 per cent. In the greater number of epidemics as yet observed in Europe, the mortality was only 50 per cent. Those who died, with two exceptions, belonged to the working class. The disease seemed most dangerous to those in advanced years or who were very young. Every person attacked who was more than sixty years of age, died, and also every child less than one year old.

Although the city of Altenburg remained in regular and free communication with the surrounding duchy, the cholera did not extend very much. It did extend somewhat, however, into the little villages of the duchy. The epidemic, however, reached over into the adjoining kingdom of Saxony, the details of which are promised in a later number of the Journal. To prevent the spread of the disease, public and private disinfection was carried out. Sulphate of iron, one pound to five or eight pounds of water, was used, to disinfect the dejections in the vessels and privies. The bodies of those who died from cholera were immediately removed to a receiving-room or vault. Soiled linen was immediately dipped in a solution of chloride of lime, and then in running water. Such a course seemed to prevent the extension of the epidemic, of which assertion many illustrations are given, which our space does not allow us to quote. *Pettenkofer* visited Altenburg during the epidemic and verified his ideas as to the essentials for the extension of cholera. His views are that first, a *carrier of the infectious material* must be had, which obtained in Altenburg in the person of the lady and child from Odessa. The diarrhœa existing in the child during the whole journey furnished in the dejections and soiled linen, this infectious material.

The second essential, according to Pettenkofer, is a surface of earth, inhabited by human beings, which is permeable for water and air down to a certain depth, and then the presence of organic material—that is, material infected with excrements, and finally, at intervals diminution in the moisture of this surface. These conditions were fulfilled in the alluvial soil, which obtains in many parts of Altenburg; and the woman who came from Odessa, unfortunately came to a house well prepared by the character of the soil under it, for the extension of the poison of cholera. The child, first seized with diarrhœa, died of debility on the 31st of August.—*Dr. Ploss, of Leipsic, in the "Zeitschrift für Medicin," etc., v. Band. 3 Heft.*

* The city of Altenburg is in the little duchy of the same name, situated on the railroad between Leipsic and Nuremburg.

East River Medical Association.—Dr. A. P. Williams was elected a member of the Association at the last regular meeting. Dr. James H. Anderson will read a paper upon "Cholera Infantum" at the next meeting, on the 2d proximo.

Changes and Appointments in the Metropolitan Health Board.—Dr. James W. McLean has been appointed sanitary inspector, vice Dr. Robert Newman sailed for Europe, and Dr. Lewis Applegate has been elected clerk, vice Dr. McLean promoted.

Health of Philadelphia.—Previously to every epidemic of cholera which has prevailed in this city an epidemic constitution of the atmosphere has always manifested itself in an increase of deaths from bowel affections. No such condition of things seems to exist at the present moment. The whole number of deaths from cholera infantum, diarrhœa, and dysentery, for the week ending May 26, was only six, in a mortality from all diseases of 288.—*Medical News and Library.*

Errata.—Medical Society, County of New York, 3d paragraph, 5th line, page 91. after "complete division," read "of the sphincter ani muscle." On page 176, first column, 12th line from the top, read. "in America, quackery celebrates its triumphs," instead of "an American."

FACTS AND CONCLUSIONS

BEARING UPON THE QUESTIONS OF THE

INFECTIOUS CHARACTER OF ASIATIC CHOLERA,

AND THE NECESSITY OF A GENERAL, UNIFORM, AND EFFICIENT SYSTEM OF QUARANTINE AT ALL OUR PORTS,

AS COMMUNICATED IN A LETTER TO THE

HON. Z. CHANDLER, CHAIRMAN OF THE SENATE COMMITTEE ON COMMERCE.

BY CHARLES A. LEE, M.D.,
OF NEW YORK, AND
J. M. TONER, M.D.,
OF WASHINGTON, D.C.

SIR: As the question of instituting a general and uniform system of quarantine is still before the Senate, will you allow the undersigned to state briefly some of the arguments and conclusions arrived at on this subject by those who have made the cholera a special study?

Pestilential cholera, with strongly-marked infectious properties, first commenced at Jessore, a populous town in the centre of the Ganges, and cut off a majority of those whom it attacked. It spread in every direction throughout India and the adjoining countries; and although there have been at times intervals of complete immunity from its presence, it may be said to have become naturalized in India, and now forms one of the diseases of the country.

For several years it was confined to eastern and central Asia; in 1829 it invaded Russia, and the central and western countries of Europe; in 1831 it appeared, for the first time, in England, and was distinctly traced to ships arriving from Riga, Cronstadt, Hamburg, and Dantzic, where the disease prevailed, and the infection was conveyed to many places in both England and Scotland, in the clothes and bedding of sailors who had died, either in those foreign places, or on the passage of ships to English ports.

From England, the pestilence was conveyed in an emigrant vessel across the Atlantic to Quebec, in the spring of 1832, many emigrants having died with it on the passage. It broke out in a severe epidemic form at Quebec on the 6th of June, three days after landing; and on the 10th the first case occurred at Montreal, whence it extended to places on the lakes, and down the Champlain Canal and Hudson river to New York, where it appeared on the 24th of June. From thence it spread south and east, and in different directions, till it prevailed very generally over our country. In every invasion of cholera since, its course along the main routes of travel can be distinctly traced; while in large numbers of instances it has been known to be carried by persons who had been exposed to the disease in infected places, to hitherto healthy localities, and there communicated to their families, nurses, and attendants. Dr. Evans, in his memorial to Congress, has given many striking instances of the kind which occurred under his observation, where the disease was carried from Chicago, in 1849, to numerous villages in the interior of Illinois.

When the cholera first appeared in India, it was not regarded as contagious or communicable, but was believed to be of atmospheric origin, and propagated by atmospheric influences; and no special measures were adopted to prevent its spread. Year by year, however, it grew more malignant and infectious, and became a source of serious alarm to nations and governments.

Hence, for more than thirty years, it has been a subject of special study and observation by the best minds in the medical profession; and scientific commissions to investigate its nature and mode of propagation have been appointed by the chief governments of Europe; which, with great unanimity, have arrived at the following conclusions:

1st. That cholera is a peculiar and specific disease which originated in India, and has never been known to originate elsewhere, and is capable of reproducing itself under favoring circumstances in every country and climate.

2d. That the disease is portable and infectious.

3d. The more recent investigations show the great probability that the germs of the disease are contained chiefly in the dejections and excretions of the body, in every stage of the malady, from its first inception, whether its character is mild or malignant.

4th. The evidence of the portability and infectious properties of cholera is to be gathered from the history of each of the several occasions that it has prevailed in the United States.

5th. The evidence is complete to show that Asiatic or infectious cholera has never originated in the United States, but in every instance in which it has prevailed in America, has been brought in ships and landed upon our shores. A few instances of this may serve to impress this point still more strongly on the mind.

6th. During the last thirty years, ten epidemics of cholera have occurred at the New York Quarantine station, which were distinctly traced to cholera patients from ships from foreign ports; and, in six instances, at a time when there was no cholera upon our Atlantic coast.

7th. The first visitation of cholera upon our shores, through the port of Quebec, has been alluded to. The second was through the emigrant ship New York, which sailed from Havre on the 9th of November, 1848; during the passage fourteen fatal cases of cholera occurred. The ship arrived at the Quarantine station on Staten Island on the 2d December, when the sick and passengers were landed. A severe epidemic of cholera immediately broke out on the island in midwinter, causing many deaths; but, owing to strict quarantine, the disease did not reach the city.

8th. The ship Swanton, from Havre, arrived at New Orleans on the 11th December, 1848, nine days after the New York arrived at Staten Island, with 280 emigrants on board. Thirteen passengers had died with cholera on the passage. No quarantine was instituted, and the ship came to the wharf. The day after the arrival of the passengers in the city, the cholera broke out, and became epidemic.

9th. The Atlanta, from Havre, arrived at New York on the 2d of November last, with a large number of German emigrants; many had died of cholera on the passage. The disease was confined exclusively to the steerage passengers. A strict quarantine prevented the introduction of the disease into the city.

10th. It will be recollected that the steamships England put into Halifax on the 9th of last month, with some 1,200 passengers and a crew of 100 men, with a large number of German passengers who had come from places infected with cholera; 160 cases of the disease occurred on board, and fifty deaths during the passage. Owing to strict quarantine at Quebec, the disease was checked there, and the ship is now at quarantine in New York—the passengers having been landed after undergoing the usual quarantine. It will

also be remembered that on the 18th of April, now nearly one month ago, the steamship Virginia arrived at New York with over 1,000 passengers, most of them Germans, many of them from infected places in Germany, where they had been exposed to the disease. About fifty died of cholera on the passage. Many new cases have occurred among the passengers since her arrival, but the disease, by strict quarantine, has been kept out of the city, nor has it spread in any direction.

The above cases serve to illustrate forcibly the success of an efficient quarantine.

11th. The cholera had never appeared on the coast of South Carolina before the arrival of the brig Amelia, in October, 1832, which was wrecked on Folly Island. She had sailed from New York on the 19th of October, 1832, bound to New Orleans, with over one hundred passengers; twenty-four had died of cholera on the passage. After being shipwrecked, a body of wreckers went over from Charleston to secure the vessel and cargo. Most of them were attacked with cholera, and eight of them died. Eighteen men had been detailed from the city guard to act as a *cordon sanitaire;* they communicated freely with the sick and passengers, and every one of them was speedily attacked with the disease. Of the four negroes, who were the sole residents on the island, three died of cholera within a few days.

12th. Cholera had never appeared at Key West until the arrival of the Ajax, which had sailed from the infected port of New Orleans with the disease on board, when it immediately broke out on the landing of the passengers.

13th. These are but a few of the instances that might be given where cholera has been carried from one place to another in ships; and, although the disease is not contagious, in the same manner as small-pox and scarlet fever, yet there can be no longer any doubt that it spreads by means of human intercourse. This we regard as so well established, that a practical disregard of it involves the assumption of a grave responsibility.

Cholera sometimes breaks out on board of vessels many days after they have sailed, and after a longer period has elapsed since leaving port than the longest known period of incubation of the disease. But in all such cases, we maintain that clothing from infected places or persons has been opened on board, and passengers have been exposed to these infected articles, and thus have taken the disease. Sufficient facts are now on record to warrant the assertion that the connexion between the arrival from an infected to a healthy and often isolated locality, of those sick with cholera or their effects, and the speedy appearance of the disease in that locality, is sufficiently immediate to stand in the relation of cause and effect.

14th. The negative evidence which is advanced against the infectious nature of cholera, does not weaken the accumulated force of the facts in its favor, many of which do not admit of a reasonable doubt; but it is always to be borne in mind, that the liability to the disease in healthy individuals is comparatively slight, and is diminished or strengthened by localizing causes, as filth, impurity of the air and drinking water, moisture, etc.

15th. Cholera derives its malignant and epidemic character from these localizing causes; as dark and damp habitations, filthy streets, decaying organic matters, bad drainage, local dampness, malarial influence, obstructed sewers, neglected gutters, stables, garbage, cesspools, privies, overcrowding, and neglect of ventilation; and if proper sanitary measures are adopted in our cities, towns, and villages, and the dejections of cholera patients immediately disinfected, the spread of the disease may be entirely controlled and kept within limited bounds, as it has been on Staten Island during the last year, and other places.

16th. The recent cholera epidemic in Constantinople, where it is estimated that 50,000 persons died of the disease, adds overwhelming testimony to illustrate this point. The sanitary condition of that city is exceedingly defective, all offal and filth being thrown into the streets, where it undergoes putrefaction exposed to a burning sun. The only drains are open ditches in the middle of the narrow streets; and the Turkish houses are, as a rule, wanting in the most necessary conditions of health.

17th. An examination of our consular correspondence in the office of the Secretary of State, amply confirms the preceding statements. The Hon. J. O. Putnam, U. S. Consul at Havre, writes as follows, under date of November 30, 1865:

"Cholera first made its appearance here on the 10th October. It was undoubtedly brought here by German emigrants, of whom, from the 7th to the 9th of October, there were about nine hundred, who arrived from Paris, where the disease was at its height. The emigrants were *en route* for New York. The cholera broke out among them on the morning of the 10th. Nine adults were taken to the hospital, of whom eight died in the course of forty-eight hours. There were also two or three deaths from cholera in the emigrant hotels."

Many of these German emigrants embarked in the ship Atlanta, which brought the disease to New York in November last, as above stated.

18th. Our Consul-General at Florence, T. Bigelow Lawrence, writes as follows, under date of September 25, 1865:

"I have the honor to transmit herewith a despatch from our consul at Genoa, reporting the recent appearance of a very few cases of Asiatic cholera within his district, with a general account of the malady in other portions of the kingdom, and the sanitary measures adopted against its increase and general dissemination. The history of the progress of this terrible disease during the present season *proves beyond question that it is, according to the usual acceptation of the term, contagious, and need not become epidemic where quarantine measures, combined with judicious sanitary regulations, are strictly enforced.*

"The statistics upon the subject from this kingdom so strongly support this theory, that it is ardently to be hoped the experience of Italy will serve as a guide to other nations as yet exempt from its visitation. The circulation among the municipal authorities of our Atlantic seaports of some of the facts contained in the accompanying despatch, *with a recommendation from the General Government that a rigid quarantine be enforced in the case of all vessels arriving from infected localities, may be the means of saving our country from the ravages of a pestilence which there is every reason to believe will at an early day approach its shores; but which, with the experience of Italy and the Mediterranean nations in view, need by no means obtain an established foothold therein.*"

In a subsequent letter dated "Florence, October 23, 1865," Mr. Lawrence remarks as follows: "The Asiatic cholera has greatly diminished in the infected districts in the southern and eastern portions of the Italian Kingdom, owing partly to the cool autumnal weather, *and in a still greater measure to the strict sanitary and quarantine regulations which have been rigidly enforced. The efficiency of these measures may be considered tested, and their value proved in the case of Italy, where the pestilence is diminishing; while in France, where the climate is more temperate, and the good habits of the people much more favorable to health, it is greatly on the increase.*"

The United States Consul, J. A. Johnson, at Beirut, Syria, writes to the Secretary of State as follows, under date of February 28, 1866:

"*The cholera was introduced into Beirut from Egypt by steamers*, some of whose passengers died *en route* in the quarantine, and in the streets and houses of the town." He also states that the disease could be traced distinctly *from place to place by means of human intercourse*, and that it was kept out of places by strict quarantine. He reports that "the cholera was brought into Damascus by the guards of the pilgrims, who opened the packages of clothing they had plundered from the dead, and that it first appeared in the locality inhabited by them."

The Vice-Consul at Aleppo reports, "*that the disease was brought there by fugitives from the coast towns, and was increased by the arrival of thirty putrid bodies brought by pilgrims for burial.*" *He also states that both at Aleppo and Damascus*, "*those who maintained a strict quarantine in their houses were not infected;*" *that* "*cholera was first brought to Syria in* 1832, *by Moslem pilgrims from Hijas;*" *and that in* 1848, *the infection was introduced into Damascus by Moslem pilgrims from the north.* "I have learned," he adds, "from the English Consul-General, that on the arrival from Egypt of an infected steamer, which was permitted to perform a three days' quarantine off Beirut, almost the entire crew of a British corvette, lying at anchor to windward, suffered severely from diarrhœa. Quarantines, to be efficacious, should be located several miles distant from populated cities. *The cholera is no doubt a product of India, and is carried by pilgrims, through rapid steam communication*, to Mecca, where the immense crowds of half-famished devotees, already sickened by the putrid remains of sacrifices, furnish circumstances favorable to the rapid increase and spread of the poison." "*A quarantine on all vessels arriving at Jeddah and Bassorah, and all pilgrims at Suez, might do much towards stifling this scourge in its infancy, or, at least, to confine it to the country in which it is indigenous.*" "It is to be hoped," says our Consul, "that the cholera conference, now in session at Constantinople, may accomplish this, if no more; else it is to be feared that the visitation of this dreadful plague will become annual in Europe, and possibly in America."

The testimony of all our Consuls abroad where cholera has prevailed, is to the same effect; and the opinion of physicians in Europe has been constantly tending to a belief in the portable and infectious character of the disease, till there is at this time great unanimity on the subject.

In the United States, except at a few of our larger ports, as New York and Philadelphia, quarantine against foreign pestilence has been either imperfectly enforced or not instituted at all, and our country is absolutely at the mercy of any foreign infectious pestilence that may be brought into it. If quarantines are, in some measure, destructive to commerce and burdensome to the merchant, they are also protective of his life and conducive to his interest. The pecuniary loss of a hundred years by the quarantine establishment of a large city cannot equal the ruin and desolation of a single season of the pestilence. It is a remark of the learned Dr. Copland, that "*to the entire neglect of government measures of prevention, and to insufficiently strict quarantine regulations, the extension of the cholera pestilence throughout the countries of the East, and through Europe and America, is entirely to be imputed.*"

In regard to the question of quarantine, we take it for granted that every right-minded person will agree that it is not only the province, but the duty of a State or nation, to enforce, through its local authorities in every part of the country, such sanitary measures as will prevent a domestic origin of pestilential diseases. It follows, then, that if it is proper for the Government to endeavor to prevent, by proper legislation and police inspection, the origin of infectious diseases, it is equally its duty to see that no portable or infectious disease be permitted to spread from an infected to an adjacent and healthy locality. Indeed, we believe that each State, municipality, and city, throughout our country, possesses the right to surround itself with a *cordon sanitaire*, if it chooses, so as to prevent infected persons or things from entering its borders, either by land or water. There can be no question that if truly contagious disease, whether of foreign or domestic origin, was to break out or prevail in any one of our large cities, it would soon be conveyed by persons or effects, coastwise or overland, to all the other cities, unless prevented by an internal quarantine. However, the chief danger to be apprehended in the United States from pestilential and communicable diseases arises from the facility with which they may be imported and landed from foreign countries, in consequence of our inefficient system of quarantine.

We apprehend there is no apology necessary for making suggestions at this time that may assist in devising and putting in practice a system of quarantine that will, in conjunction with internal sanitary regulations, prevent the introduction into our country of foreign and communicable diseases.

Those who believe in either the domestic origin or the atmospheric importation and spread of yellow fever, cholera, etc., place little or no reliance upon a *cordon sanitaire* or quarantine regulations.

Quarantine, as at present conducted, is opposed by ship-masters and importing merchants, on the ground that it unnecessarily and ruinously taxes, impedes, and restricts commerce. That there may have been arbitrary exactions and unnecessary detentions imposed upon shipping and passengers through faulty quarantine legislation by the different States, in their desire to prevent the introduction of foreign, portable, and infectious diseases, we will not pretend to deny. In many instances the want of suitable quarantine grounds, and the other necessary means of carrying into effect the principles of isolation and disinfection recognised as being essential to the success of such laws, has almost made failure a necessity, and brought the practice of quarantine into discredit.

Some philanthropic individuals oppose quarantine from the belief that many deaths occur there among passengers not sick when they arrive, and whose lives might be saved were they permitted to depart, but who contract the prevailing disease in consequence of the inhumanity of confining all, whether sick or well, in the same hospital, without that degree of classification or isolation that experience teaches to be essential to safety.

There is also a respectable and highly influential class of physicians and gentlemen who plant themselves on the broad ground of non-contagion in yellow fever and cholera, and therefore oppose all quarantine of persons. They, however, admit the necessity of throwing some protection around the community by favoring the fumigation and disinfection of vessels and cargoes when there has been much sickness upon the voyage or deaths from a specific and communicable disease. This class of physicians hold that the *materies morbi* or *fomites*, which are the cause of epidemics, and which are by many considered contagious, are purely atmospheric, and are carried in the confined air of ships, in merchandise, and through the open air, across the ocean and over a continent.

As a general rule, they leave out of view the important fact that there is a variable period of incubation in

most infectious diseases which extends from a few hours to ten or fifteen days. Suppose we grant that the essential poison of a communicable disease is not organic, there is, nevertheless, an incubatory period in all such diseases, so that a passenger may leave an infected ship apparently in perfect health, and may even have taken the precaution to have his clothing and trunks disinfected and fumigated, nevertheless the disease may be developed after having lain dormant in his system ten or twelve days, and thus, in some distant city or place, establish a new centre for the dispersion of the poison from which others coming within the sphere of its action may be affected, and the disease spread indefinitely.

Believing as we do that neither communicable yellow fever nor cholera has ever originated within the United States, and that the first cases in each of the epidemics which have prevailed in our country can be traced directly to infected emigrant ships or to passengers, merchandise, or personal effects which have been brought from infected vessels or foreign ports, we therefore contend that if an efficient and uniform system of quarantine be established at every port in the United States through which passengers or foreign merchandise arrive, these diseases may be prevented from entering and spreading over our country.

With the improvements which modern chemistry and science have placed in the hands of the profession, we are enabled to facilitate commerce by a speedy and thorough disinfection of a vessel and cargo, without the delay of first unloading it. We believe that the period of detention of passengers at quarantine may be materially shortened, and its dangers greatly lessened, by establishing a proper system of inspection and classification of all persons landing from infected vessels or ports, into the "infected," the "suspected," and the "healthy," and maintaining a rigid non-intercourse between the several classes.

Uniformity in the system of quarantine to be observed at each of the ports of the United States demands that all the doors against portable and infectious diseases should be closed, and no one port have any commercial advantage over another, by a longer or shorter detention of vessels, cargoes, or passengers.

Quarantine should not be enforced upon vessels, cargoes, or passengers unless arriving from or having landed at an infected port within a shorter period than the prevalent contagion requires for its development, or upon whose passage a disease of a portable and infectious nature had prevailed.

The assertion that quarantine has never kept cholera out of any country or city is a gratuitous assumption. Numerous instances and facts exist in proof of the contrary, as has been shown in Spain, Greece, and Italy, and recently at New York, Quebec, and Halifax. But should the present notoriously inefficient system of quarantine as practised at many of our ports fail, it would militate nothing against the principle recommended, but only be a further proof of the inefficiency of quarantine as now conducted. We know, as does every person at all familiar with American quarantine, that there is not that perfect system of inspection, sequestration, and isolation among the different classes of patients that humanity demands, and the nature of portable and infectious diseases requires for their complete arrest and annihilation.

The purpose of a quarantine, and the nature of the diseases met with there, make it obvious to a practical mind that every properly organized quarantine establishment requires to be located at a considerable distance from thickly-populated districts, and to have extensive grounds for anchorage, and separate and distinct hospital departments, so as to allow a proper classification of all persons arriving at the station. 1. A receiving and inspection. 2. A general hospital department for all cases of accident, and diseases other than those of a contagious character. 3. A hospital for infectious diseases. 4. A department for the suspected, in whom contagious disease may or may not be developed. 5. A department for the convalescent. 6. A department for those who are unaffected, and in the enjoyment of good health, but who for prudential reasons should be detained, after leaving an infected vessel, a time equal to the longest known incubatory period of the prevalent disease. As quarantine is most essential during the months from May to November, and not likely to be called for during the remainder of the year, it is not thought that it would be necessary for the Government to erect expensive warehouses and separate hospital departments at each of the quarantine stations. Temporary tents or tenements would answer. The Government has no doubt in its possession a vast number of army tents or barracks which would answer admirably at most of the stations. The essential conditions of an efficient quarantine are, a good wide anchorage-ground to the windward of the hospitals; warehouses for a class of goods which cannot be so speedily disinfected as to make it safe to land it with the rest of the cargo; and hospitals properly separated for the accommodation of patients according to their condition. If a principle of this kind, founded upon separation and non-intercourse of the departments, furnished with the most approved styles of water-closets and privies, were adopted at quarantine, the apprehensions and mortality from cholera would be greatly lessened. This principle of complete separation and sequestration of departments, with a space of a hundred or more feet between, and such subdivisions of departments as circumstances and experience may suggest, would, no doubt, have the effect to arrest and successfully prevent the introduction of cholera.

There is, we grant, just cause to complain of a system of quarantine which would confine those affected with actual cholera—the suspected, the convalescent, and the healthy—all together in the same vessel or hospital. Indeed, it is no wonder the plan practised in most of our ports, which is only a quarantine in name, should fail either to prevent the introduction or diffusion throughout the country of portable and infectious diseases.

The reason for putting the convalescent and healthy in separate departments is, lest the convalescent should by chance carry with them some trace of the disease, or relapse, and thus expose all those in a hitherto healthy quarter to the infection before the former could be removed. All well regulated hospitals throughout the country adopt the common-sense practice of keeping those afflicted with infectious diseases separate from the main building. What surgeon would not immediately remove an erysipelatous case from his surgical ward, or a typhoid or typhus fever case from among his other patients?

Humanity, and the enlightenment of the age, demand that a principle in quarantine be adopted, that all passengers from an infected ship be landed for treatment, and separated into classes in accordance with their actual condition of health, and cared for in suitable and separate departments, attended by an efficient corps of physicians and servants, and furnished with all the comforts essential to their condition; that they should have no communication with other departments; and that between these departments there should be maintained absolute non-intercourse, either of patients, nurses, clerks, physicians, or others, except by telegraph.

The clothing and personal effects of a passenger, on entering quarantine, should undergo disinfection, by

heat or otherwise, and all that is not absolutely needed for personal comfort should be forwarded to the convalescent or final quarantine department.

A very feasible plan of quarantine for cholera, with great minuteness of detail, has been submitted to the profession by Dr. W. Marsden, of Quebec. But if the Federal Government, or the different State authorities, with the aid and assistance of the General Government, adopt a uniform system of inspection and quarantine at all the ports where foreign commerce enters, on the theory of classifying the patients and keeping them in separate and isolated departments, and a speedy disinfection of the cargo, the details and mode of carrying the plan into operation had better be left to the judgment of the medical officer in charge, and to the exigencies that may arise at the different quarantine stations.

Dr. Copland, in his "Dictionary of Practical Medicine," lays down the following principles as essential to a proper and efficient quarantine of contagious diseases. "The sanitary division of the healthy into the susceptible and the non-susceptible, or those previously attacked, naturally dictates the classification of the sick into the decidedly infected, the suspected, and the unsuspected. There should therefore be three distinct hospital establishments, viz.: 1. The foul lazaretto, for pronounced cases. 2. The lazaretto of observation, for those cases which may or may not turn out to be infected. 3. The free or clean hospital, for accidents or non-susceptible sick. All the attendants of the first and second establishments—medical, clerical, and others—should be kept, if possible, in quarantine."

We would most earnestly recommend that all ships arriving with passengers on board among whom cholera or other foreign infectious diseases prevail, be required to land their passengers, to be treated in hospitals prepared for the purpose, and the vessel and cargo be turned over to proper officers to have her bilge-water removed, and to be disinfected and thoroughly fumigated and cleaned.

With the powerful disinfectants which the chemist has placed in the hands of the medical profession, capable of destroying all gaseous compounds as well as organic matter, we can see no reason why vessels and cargoes may not be disinfected within forty-eight hours after the passengers have been landed.

The effects of the steerage passengers, who are the most frequent sufferers, and the least able to sustain losses, either of baggage or time, ought to be thoroughly purified without material injury, and be subjected to the same detention, and no more, than that of other passengers

Humanity, as well as propriety, suggests that the condition of all who are detained at quarantine be made as comfortable as circumstances will permit, and that they be made as secure against the hazard of contracting the prevailing infection while at quarantine as possible.

Those disposed to supply themselves with clothing, food, and other articles of personal comfort, not supplied by the regulations of the establishment, which should be ample, ought nevertheless to be permitted to do so, unless, in the opinion of the medical officer, the demand would be injurious to health or discipline.

If a system of quarantine, based upon the principles indicated in this article, be enforced with uniformity and efficiency at all the ports of the United States, we feel entirely confident that not only cholera, but all other foreign and infectious disease, will be excluded from our country. That such a system would be a great amelioration of the dangers and hardships experienced by passengers who are required to undergo quarantine under the present regulations, is self-evident.

The shipping interest, too, will be greatly benefited by the inauguration of the system suggested, which provides that all the passengers be landed and treated in hospital, and, instead of detaining the vessel and cargo for months, as at present practised, they may be thoroughly disinfected within two or three days, after which they can safely be permitted to go into port and unload.

Washington, D. C., May 14, 1866.

POLYCYSTIC DISEASE OF BOTH OVARIES.—OVARIOTOMY.—RECOVERY.

By JOSEPH CREAMER, M.D.,

BROOKLYN, E. D.

On the twentieth of April I was consulted by Sarah Weildon, from whom I obtained the following history. She is forty-three years old; married twenty-one years, and the mother of seven children. Eight years ago, after a very tedious labor, she gave birth to a daughter. Her convalescence was unusually protracted, three months having elapsed after the accouchement before she felt sufficiently able to resume her customary household duties. She observed at this time that her abdomen did not regain its usual size, as after previous confinements; but, on the contrary, was slowly enlarging, which it continued to do for the space of eighteen months, when her attending physician tapped her, and drew off four gallons of fluid. Twelve months after the operation she gave birth to her last child, a healthy boy, now five years old. Has had two miscarriages since birth of boy; one twelve months, and the other two years after his birth. Doubtless at about this period the ovaries began to take on diseased action, for immediately after the first miscarriage she discovered a lump in the right side of her belly, which increased sufficiently during the past four years to interfere with important functions. On examination I found the extremities œdematous, the abdomen considerably enlarged, and measuring thirty-four inches and a half round the umbilicus. As she had obtained the opinion of a distinguished teacher in medicine, who pronounced emphatically on the character of the tumor, and advised strongly against surgical interference, I hesitated upon giving a positive opinion until consulting with some gentleman of more extended experience in abdominal tumors than myself; consequently I directed my patient to see Prof. C. A. Budd, who kindly examined the case with me, and unhesitatingly decided that the tumor was multilocular and the patient peculiarly adapted constitutionally for the operation, an opinion which the result has verified in every particular.

I prepared my patient for the proceeding by feeding her on oatmeal porridge and milk for three or four days, and forty-eight hours before operating, I gave her half a drachm of rhubarb and magnesia, which unloaded the intestinal canal. On Thursday, May 3d, in presence of Drs. Donner, Feeley, and Fisk, I operated by an incision on the linea alba of eight inches in length, and which extended from the umbilicus to the pubes. After opening the peritoneum and slitting it upwards and downwards with a probe-pointed bistoury to the full extent of the external wound, I found the omentum completely adherent to the superior surface of the tumor. Adhesions also existed between the sac and abdominal walls, and were very strong, especially at the seat of the old tapping, where they required some touches of the scalpel for removal. Happily no adhesions existed posteriorly. After carefully breaking up the adhesions between the sac and omentum, which required the application of considerable force before they

yielded, I then brought the sac forwards and tapped it with a large trocar, carrying a canula half an inch in diameter, which permitted the viscid fluid to pass without loss of time. Several smaller cysts were rapidly emptied in the same manner. The tumor was now turned out from the abdomen, and the pedicle exposed, which was about four inches long, and when unravelled, two inches in breadth. I passed a needle armed with a strong silk ligature through the centre of the pedicle, and strangulated it in two lateral halves; then cut the pedicle an inch outside the ligatures, cutting the latter short and dropping the whole into the peritoneal cavity. I now turned my attention to the left side; and, on bringing the left ovary to view, found it also the seat of cystic difficulty. It was treated in the same manner as the right ovary.

The wound was brought together by six points of alternate silver wire and silk suture passed through the peritoneum, adhesive straps in the intervals, a compress of cotton wool laid longitudinally each side of the wound, and the whole secured by a flannel roller.

But a trifle of fluid escaped into the abdominal cavity, so that my colleagues agreed with me in the propriety of avoiding a source of danger by sponging the pelvic cavity; so all was left to take its chance with the ligatures.

The operation occupied in all one hour from the moment of complete anæsthesia until she was placed in her bed. I visited her at eight o'clock P. M., two hours after the operation, and found my patient with a pulse of 120, complaining of difficulty of breathing, and a feeling of soreness in the wound. I ordered half a drachm of Majendie's solution, and found her much easier on my visit at ten o'clock, when I drew off eight ounces of urine. 4th.—She spent a very comfortable night, expresses herself as quite easy, and in great hopes of a speedy recovery. In addition to sucking small pieces of ice, which she has done constantly since the operation, I directed her to take small quantities of beef-tea during the day.

On *Monday*, the 7*th*, at two o'clock P.M. I removed four of the sutures, and found the wound healed by first intention. *Tuesday* 8th.—Removed remainder of sutures, and supported the parts well by adhesive straps and bandage.

Wednesday, 9*th*.—Complains of great uneasiness in the rectum, with some slight abdominal pain coming on in paroxysms, for which I administered an enema of warm water, which brought away two copious liquid motions, with much relief. *Friday*, 11th.—Diarrhœa set in and continued with some intermissions until the eighteenth, and left her very much prostrated. Her condition on *Saturday*, the 12th, caused me much anxiety; the abdomen became enormously distended with flatus, so much so that respiration was in some measure interfered with. I directed turpentine to be sprinkled on wool and placed in a position so as to be easily inhaled; also during the night fifteen drops of the same, suspended in mucilage, every two hours.

13*th*.—Respiration improved, and the abdomen less tense, but still sufficiently distended to warrant me in administering a terebinthinate enema, which brought away the balance of flatus, leaving her much relieved. The diarrhœa was completely arrested by the free administration of vegetable astringents and suppositories of opium, which latter, being invariably introduced in the evening, procured her a comfortable night's rest. From the eighteenth until the present she has had an uninterrupted return to health; and on Sunday, June 3d, one month from the date of the operation, I allowed her to return to her usual pursuits.

A mixture of equal parts of chloroform and ether was used, and the patient was not permitted to come from under the influence of the anæsthetic until placed comfortably in bed, where she gradually returned to consciousness without an unpleasant symptom.

The mode in which the pedicle was treated I believe to be *the one* attended with the least inconvenience and danger to the subject of ovariotomy. No ligatures pass through the wound, to perhaps become sources of irritation, and the dragging of the clamp is avoided. The method belongs to American surgery, and is deserving of a fair trial at the hands of the profession in this country. The honor belongs to Dr. D. L. Rogers, of New York, who first brought it into notice in 1829. He was followed by Bellinger in 1835; by Dr. Siebold of Darmstadt in 1846; and recently by Dr. Tyler Smith of London. The first three were successful, and Dr. Smith has also had great success. The objection of J. B. Brown to the method is based on the unfortunate results in his hands following its use. He appears to lean towards the actual cautery, which is doubtless, after the method of Rogers, the least objectionable.

The selection of suitable cases, their preparation previous to operating, together with the most strict attention to the after-treatment, meeting vigorously and promptly every symptom that may arise having a dangerous tendency, has without doubt a great influence on the successful results in ovariotomy.

To Dr. Fisk my thanks are due for the skilful and thorough manner in which he administered the anæsthetic. To Drs. Seely and Donner I am also under obligations for their valuable assistance during the operation, and in an especial manner to the latter gentleman for the interest he manifested throughout the after-treatment of the case.

Original Lectures.

ON CHOLERA.

By A. CLARK, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

Lecture VI.

The Portability of Cholera—Can Cholera be Excluded by Quarantine?—Will the Disease appear here this Summer?—The Circumstances which Increase the Fatality of Cholera—When Epidemic, the Disease is produced by a Special Miasm—The Time of Day when the attack begins.

I have yet a few words more to say, gentlemen, in regard to the portability of the poison of cholera. I had stated to you how it first arrived upon our shores, and was describing to you the manner in which the second great advent occurred. The Swanton reached New Orleans on the 11th day of December. On the 13th the first case of cholera occurred in the city. During the remainder of the month there were eight hundred and sixty-three deaths from the disease then imported. In January there were seven hundred and three deaths; in February one hundred and eighty-seven; in March seven hundred and ten; in April three hundred and ninety-two; in May four hundred and fifty; in June two thousand five hundred and thirty-three; in July twenty-one; in August one.

After June it rapidly subsided. In the meantime it had ascended the great river that passes New Orleans, and had appeared in St. Louis on the fifth of January, attacking at first, however, only the newly arrived emigrants. Thus it was fairly introduced into that part

of our country. At the point of attack on the Eastern coast, as I have said, it ceased after one month of epidemic prevalence at the Quarantine of New York. But the next spring, ships arrived bringing emigrants affected with the same disease, and it reappeared as an epidemic on the same ground; and on the 11th of May the first case occurred in this city. It then became epidemic, followed its usual course, and subsided in the autumn; spreading, however, from New York pretty directly to the larger cities on the great lines of travel—Troy, Albany, Utica, Buffalo, Chicago, and others.

In 1854 its history was analogous. As I have already told you, a ship from Hamburg, then an infected port, carrying German emigrants, on the 22d of August, 1853, brought the disease to Liverpool. The same thing occurred on the Eastern coast a few days later, and it became epidemic in these places, and soon after in various towns in the northern part of England and in Scotland, prevailing during the whole winter and spring, reserving, however, its greatest violence for the following summer. In the autumn of 1853 ships from infected ports arrived in great numbers in the harbor of New York, bringing emigrants affected with this disease. Indeed it is reported for this port alone, that on board of twenty-eight ships, arriving in the month of November, one thousand one hundred and forty-one persons had died of cholera. In fact, ships bringing this unwelcome freight continued to arrive during the winter and spring. But the first appearance of cholera in the Northern division of the United States was not in New York; it was not even on Staten Island; but it was in Chicago, in the latter part of April, 1854. It broke out there among the recently arrived emigrants, continued to be mild until June, when it was declared epidemic. On the 16th of May the same class of persons, recently arrived emigrants, were seized with the disease in Detroit; and still it was not in New York. During the whole month of May of this year there was but one death from cholera in this city. The epidemic of that year dates from the 14th of June. Then, in Chicago and in Detroit, the outbreak of the disease preceded its outbreak here; and why? Those places are in the principal line of emigrant travel; the emigrants passed through New York, to be sure, but they were in good health at that time. They passed on to those cities, and were there seized with the disease, although cholera had not visited either of the cities since 1849. Why should emigrants coming from the infected ports of Europe in infected vessels be attacked, to the exclusion of other persons? Plainly, to my mind, because they carried about with them, in clothing or baggage, a poison capable of regenerating itself and spreading abroad an influence that in the warm months produced a general epidemic.

An emigrant ship from Liverpool in 1843, bound for New Orleans, touched at the Island of Nevis in the West Indies. Her passengers were suffering with cholera, and it was not long before the whole island was affected with the disease. During the past year a ship similarly affected is reported to have touched at Guadaloupe; and since then the cholera has been prevailing in that island.

Now, all this goes to the point of showing that cholera can be transported. It is true that every chapter of this history taken alone, may be claimed as proof of contagion; yet the facts none the less prove its transportability, and the transported thing may as well be, and on previous showing probably is, a miasm. Whichever of these views you entertain, this transportability of the disease, it seems to me, is perfectly demonstrated. In this country there are a few, and only a few, who doubt it.

Then upon this comes the question—Can it be excluded by quarantine? The general conviction in Europe seems to be that quarantines are of no service. Quarantines, for the most part, as they have been enforced there, have not prevented the invasion of the disease, unless perhaps one little town be regarded as an exception. There is, on a neck of land made by a bend in the Volga, a settlement of Moravians that has been for a great while the admiration of all travellers for its neatness, perfect cleanliness, and for the good habits of the people. When the cholera has marched up the Volga, assailing almost every town in three several epidemics, this clean little Moravian Serepta has been left untouched. It is said, to be sure, in Copland's dictionary, that the authorities preserved a strict quarantine, and admitted nothing that could bring the disease to them; but whether it was from quarantine or from cleanliness, they seem to have escaped entirely. In its other relations quarantine seems not to have been effectual; but is it not plain, from the history I have given you of the several importations of the disease into this country, and into England, Scotland, Ireland, Nevis, and Guadaloupe, that if passengers and goods whose admission into these countries and islands was coincident with the outbreak of cholera could have been excluded or kept at a sufficient distance, the disease itself might have been excluded also? It does not seem to me that the question of quarantine is to be abruptly decided in the negative. Whatever may be said of the failures in Europe, whether they have arisen from incomplete restrictions and impracticability, or from the epidemic constitution of the atmosphere, or the admission of diarrhœa while cholera was excluded—here, far away from the sources of the disease, the great ocean intervening, at a distance that the miasm cannot reach, the rule may well be reversed. Experience has fully shown that as in armies, so in ships, the disease has a limited existence. It has repeatedly been brought into our harbor when it has not invaded our city. It may even become epidemic at the Quarantine Hospital, and the city escape. I have already called your attention to two instances of this occurrence. It appears from the *Report on Cholera of the Council of Hygiene and Public Health* (Citizens' Association), that there have been at least *fourteen* such epidemics within the old Quarantine inclosure, and it is well known that the city has been visited but four times. There have been then ten epidemics at that station which did not extend beyond its wall, or at least beyond the shores of the island on which that institution is situated. "Ten of these fourteen epidemics," the writer says, "unquestionably depended on cholera patients from ships, and in six instances at a time when there was no cholera upon our Atlantic coast." Can it be said then that quarantine, even in the slipshod and inadequate manner in which it has for the most part been enforced, has been a failure here? For it will hardly be claimed, such is the attraction of cholera towards large cities, that on these occasions the atmosphere of New York was free from those certain elements which are susceptible of poisonous transformation under the influence of the cholera poison, when at a distance of only six miles in the open country those elements demonstrated their presence in violent epidemics. Yellow fever has probably been a hundred times confined to our harbor, when it has been brought here in ships, since its last epidemic prevalence in 1822; and if the virus of cholera poison is a miasm, as that of yellow fever is believed to be, it ought to be subject equally to exclusion by the same means. If, indeed, the disease is propagated by the discharges unchanged, or fermented, or combined with telluric agencies, all the more should it be subject to exclusion by force of iso-

lation, time, disinfectants, and sea-water. It has already had a success at this port which of itself goes far to disprove the doctrine that the malady is propagated by an atmospheric constitution alone. Quarantine, I repeat, has not been a failure in this country. Its rigid enforcement entails much personal suffering among passengers, and often heavy losses on property; and for those reasons it is often so relaxed as to be ineffectual. But I fully believe that, with the proper agencies and accommodations which it is notorious the port of New York now wofully lacks, the pestilence could be excluded in its approaches from the sea, for ever. If this is true of New York, it is true of every port in the country; and if it is true, as I believe it is, that the disease has never visited this side of the Atlantic except by the aid of importation, this would amount to perpetual exclusion. Amidst contending interests, it may be sometimes difficult to decide what the precise duty of the authorities may be in those matters. I have given you the facts, and yet you must form your own opinion as to the value of quarantine. If it is possible to ascertain whether the poison can be transported by the wind, or in the air—and if so, how far—and in that way extend its ravages, it would aid in deciding the distance at which quarantine rules should be enforced.

At this point, perhaps, as well as at any other, I can answer a question frequently asked me: "Do you expect the cholera will appear in this city the next spring or summer?" The fact that it has prevailed here in former years after it has prevailed in Europe leads to the conjecture that it will reappear. But there are certain important points of difference in the epidemics that have reached us and that now existing in Europe. In other instances, it has been lingering in commercial towns in Europe during the whole winter. It did not wait to spring up anew in the year in which it visited us; but it affected those towns the autumn or even the summer before, and continued somewhere within reach of commerce. The present winter we hear nothing of these occurrences; we do not know (March 2d) that there is a single case in London, or Liverpool, or Hamburg, or Havre; we do not know* that there is a single case in any seaport in the whole of Europe at this moment. Again, the visitations that have reached this country, and became epidemic, have been progressive uniformly from the central portions of India, and their progress has been regularly traced. The first began, as you have been already informed, in 1817, and pursued its course very slowly, stopping at Astrachan for a period of seven years, and then renewing its march, or rather repeating and extending it. The second began in 1844, in the delta of the Ganges, gradually extended westward, and reached us, we may say, perhaps in the autumn of 1848, or at any rate in the spring of 1849. Its progress was northward as well as westward. In each instance it invaded the Russian and German towns on its way, including Hamburg. It has reached England more frequently from Hamburg than from any other port. The third general epidemic is found at Bussorah, and also in Bohemia, in 1851; at Bagdad and in Poland in 1852, reaching St. Petersburg in October of that year. It prevailed extensively in northern Europe in 1853, visiting Hamburg on the 28th of July and Liverpool the 22d of August, still approaching by the northern route. This year its progress has been different. The first we hear of it is among the caravans of pilgrims from Mecca moving westward, and we are not informed that it began in the delta of the Ganges, or even in India. All we at present know is, that it prevailed at Mecca, and was by the pilgrims brought to Egypt, and from Egypt spread to Turkey, and various ports and places on the Mediterranean, and connected waters. By way of Marseilles, which was pretty severely visited, it reached Paris. It did not become epidemic in England. A few cases were reported as occurring at Southampton, in the autumn, but it has not yet visited any other part of England so far as we know. In these respects there is certainly a difference in the history of the diseases that have reached us and the one that has not. The shortest period in which it has thus far travelled from Asia to New York is three years; the disease we now fear is yet hardly twelve months old. Again, in two instances in which it became epidemic in New York, and so spread through the country, it was brought to Staten Island, and prevailed there as a local epidemic during the autumn or winter preceding its outbreak in the city. Now, we do not know that at Staten Island, or in any place where cholera patients have been brought, there has been any extension of the disease from new generation of the matter that produces it. True, the Atlanta brought the cholera into the harbor, and her sick were treated on the hospital ship in the lower bay. The patients who were detained on the ship, some of them sickened, but it did not spread to any point on the land.* Now, then, the analogy between the former epidemics and this that has visited Europe, you observe does not hold; and I should hardly expect that it will reach this country at all, unless it comes from English, or German, or French ports, or places from which emigrants reach them; and, as I said before, we have no knowledge that the disease prevails in any of those places.† It did not, as on two previous occasions, make a lodgment in New Orleans the autumn or winter before it appeared as a wide-spread epidemic in this country. The argument, then, that it will visit us, from the history of the epidemics that have prevailed, is not complete. In referring to the regions which, if infected, are most likely to send the disease to our shores, I have omitted those that are comparatively distant. The cholera on shipboard does not often continue beyond thirty or forty days. On board the English transport-ship Apollo, in 1849, it remained while at sea fifty-four days, but after the thirty-fifth day there was only a case "at intervals." Ships do not often arrive at this port in which the disease has exhausted itself; but New Orleans is familiar with such facts. In 1848 two emigrant ships from Hamburg had cholera at sea, and entered at New Orleans in a healthy condition. But to return. If there should be a new outbreak of the disease in ports of Europe that are in constant intercourse with this country, or in regions from which there is immigration, the chances are that it will be brought here during the summer. If it does not occur in those ports or places, it seems to me we have a very good chance of escaping it. It is true it has been brought to Guadaloupe, in the West Indies. Whether it will spread to other islands in more immediate intercourse with this city, and so be brought here, we cannot tell.

I turn now to some other considerations regarding the disease—those circumstances which increase its fatality. Among these stand foremost what are called the conditions of insalubrity, the accumulation of filth, the neglect of privies and cesspools, the saturation of ground with materials thrown from houses; in general, the absence of cleanliness. Whatever the cause of cholera may be, there is a universal assent to the proposition that influences like these are pregnant with death, that they increase the fatality, and increase the liability of

* At the time this statement was made it was not known, even to the profession in the city, that there was a little outbreak of the disease at the emigrants' hospital on Ward's Island last year, after the arrival of the infected ship.

† At a later date it became known here that cholera had wintered in some of the interior German towns, and on the western coast of France, having extended from Paris.

any particular locality to this disease. Instances could be multiplied without number that would illustrate it, but this will hardly be necessary; still, I may cite to you a single instance that seems to me quite striking. Dr. Houston, in the report of cholera as it occurred in the city of Wheeling, which I have already referred to, makes the following statement. The disease appeared in the latter part of 1832 in this town; a few deaths occurred, and then it ceased. On and after May 15th of the year following, some cases occurred, chiefly among the poor and persons of bad habits, about a place in the town called Market Square. During the winter Market Square had been neglected; filth of every sort had accumulated there, and the sweepings of the market had been mixed with outside accumulations, and the sun and rain had been doing their work upon this morbific mass. At length, after cholera appeared, the authorities came to the conclusion to remove it. It was all raked up into heaps, and portion after portion removed to a distance of two blocks and the width of one street, and there temporarily left upon the river bank. The wind was blowing from over this heap of filth directly towards the most populous part of the town. Between midnight and the morning of the next day every member of a family that lived in the house nearest to this point was attacked with cholera, and adjoining houses were directly attacked. In a few days the whole of the region, including Market Square, was the site of great mortality. Dr. Houston has no doubt that the mortality was increased materially by the mode in which this filth was disposed of. Perhaps another instance may illustrate the same thing, and enable you to remember it better. At Wakefield, England, stand three prisons in one inclosure. One of these, the old prison, stands close upon a sluggish stream, upon a perfectly flat piece of ground, the drains running under the building; and the water from the sluggish stream setting back through these drains, infiltrated the ground underneath. The privies were in rooms close to those frequented by the prisoners, and having free opening into them, the house is badly ventilated and badly warmed. The other prisons in the same neighborhood were in a good sanitary condition; the drains were outside the building, and well constructed, and the houses were built with a view to ventilation and warmth. The diarrhœa appeared, and affected more or less all the prisons; but cholera visited this old prison, but did not enter the others. Now, it seems from facts like these (and they can be cited in great numbers), that whatever the cause of cholera may be, it is in some manner intensified by emanations from decomposing organic matters and from unclean places; yet it is remarkable that a great many towns full of filth and all uncleanness escape entirely, or even with a very few cases, while neighboring places, in a similar condition, are heavily visited. It is not, then, filth alone that causes the disease. Whether there is ever anything in the elements of such decomposing materials that can combine with other constituents, and form the cholera poison, nobody can say; but the great practical fact remains that, in a large majority of cases, this disease does visit most severely those parts of towns and those places in the country where least attention is paid to general, domestic, and personal cleanliness, and where the people are the most abandoned.

Ventilation is, doubtless, an important element in protection from cholera; and crowding, or the bad air resulting from crowding many persons together in the same apartment or building, is doubtless a potent agent in increasing its mortality. Thousands of illustrations might be produced, but one will suffice. Dr. Hanbury Smith, who is now resident with us, but who was formerly of Cincinnati, states that, in one frame building there lived thirty-three persons; that eight of these were boarders, who occupied the four best rooms in the building; the remaining twenty-five were crowded into small rooms, five to eight in each room. Cholera attacked the inmates of this house, and of the twenty-five, twenty-three died; but of the eight boarders who occupied rooms of a larger size, not one was attacked, though they spent their time in nursing and taking care of the sick in the same house. This is certainly an unusual penalty to pay for breathing vitiated air; but tenement-houses, where often the volume of air allowed to each person does not exceed two hundred cubic feet, while one thousand feet is the least allowance that is tolerated in a well-regulated hospital, and this only with thorough ventilation, everybody knows are chosen homes of cholera.

The water that is used for drinking is probably one of the agents that increase the mortality of cholera, when it is impure. The severity with which this disease has uniformly visited the city of Paris would seem to be an illustration of this fact. The water of Paris is laxative upon strangers. That taken from the Seine is impure at all times. The striking differences in cholera mortality in different sections of London corresponding with the different sources of water supply, cited in support of Dr. Snow's theory, seem really to depend, at least in part, on the varying qualities of the water used in drinking. The severe prevalence of the disease in some of our western cities is probably to be ascribed to the same fact. The water of the Mississippi Valley produces the same effect upon strangers as the water of Paris. Not that there is in these waters any special poison; but, during the prevalence of cholera, it is generally acknowledged that whatever causes irritation of the bowels, predisposes to the disease. As a contrary fact, you will find quoted by Dr. Watson an account of two institutions in the midst of an unhealthy portion of London, where good water is obtained from Artesian wells, which were sunk before the first occurrence of cholera. In the three epidemics that have occurred in London, the inmates of these institutions, Bethlehem Hospital and House of Occupation, numbering about seven hundred, have escaped entirely, "although the disease has prevailed extensively in the parish and in the streets in the immediate vicinity." Yet it cannot be denied that cholera has visited, with considerable severity, towns and villages that are supplied with wholesome water.

It is believed that elevation has some influence on the prevalence, if not upon the mortality of this disease. Dr. Gull shows from the Registrar-General's Reports, that the higher parts of London were the parts least affected; not that there was a uniform and regular rate of mortality in proportion to the level, but, as a general fact, the points of London most elevated were the parts most free from the disease. It must, however, be taken into consideration that in London, as in almost every city, the higher portions are occupied by a better population, and are the parts least crowded and least filthy. In certain places, as in Southampton, cholera has been severe in the highest parts of the town; but the reports state that these parts were inhabited by poor people, who paid little attention to cleanliness, and that the buildings were in a filthy condition. In Paris, the mortality was least on the lower levels as a rule, and the richer people of Paris live on these lower levels. It does not seem, then, that elevation alone will prevent cholera, if other circumstances favoring it be neglected. Then, too, in the broader view of its prevalence, looking over the whole of the countries visited by it, mountainous regions are those which most often escape. In such regions, the population is usually thin and scatter-

ed, the villages are small, and cities are rarely found. In England, a very large proportion of the island has never been visited by cholera; but it is not the commercial towns that escape; it is the inland positions, and the elevated positions where the population is sparse. The same thing is true of our own country; there are large regions that have not been visited at all. I doubt whether there has ever been a case of cholera in Vermont, except on the shores of Lake Champlain, which is one of the highways of travel. In New Hampshire, I doubt whether there has been any cholera, except perhaps at its seaport. In the interior of Massachusetts, cholera is all but unknown. In the town of Pittsfield, I can testify to the occurrence of three cases; but it did not become epidemic. Still cholera can ascend to considerable heights. Dr. Nicholas Parker states that it occurred at Landor, eight thousand feet above the level of the sea. In 1854 it occurred at Mexico, seven thousand feet above the sea. Mere elevation, then, does not furnish complete protection.

Another question: Can the poison of this disease be blown about by the winds? The fact that I cited to you a little time ago, that Dr. Bryson found the cholera upon an English fleet while the ships were several miles from shore, and before any intercourse had taken place, would seem to imply that the wind can be a carrier of the poison. Instances are quoted over and over of ships lying in the harbors of infected towns, not being affected until the wind blew off from the shore, or from the direction of another ship that was infected. It may be true that the poison can be carried a certain limited distance; but analogy urges the improbability of its being carried "several miles" before it would be so diffused and diluted as to lose its potency. The idea founded on Dr. Parkes' suggestion, that in India the wind carried the poison ninety miles to fall upon Madras; and the notion of Dr. Biggs, that it was wafted from Belfast to Armagh in Ireland, a distance of at least thirty miles, while in each case it is understood that the intermediate places were not touched by it—are little better than absurd. The striking fact in the cases of the *Fairlie* and *Coutts*, anchored in the harbor of Madras, was that in the first, the men who worked on deck and those who slept on the landward side of the ship, were those who principally suffered; while in the *Coutts*, of twenty-three attacked, twenty-two slept on the same landward side. In each case, the landward was the windward side. But while ascribing this disease to the agency of the wind, there is no attempt to exclude the influences of intercourse with the infected shore, the bringing on board supplies, etc. Then, if any agency of the wind is admitted, the currents would pass freely through the ships from windward to leeward ports; so that it is difficult to understand how the windward men were more exposed. The supposition that the ships were themselves infected, and that local causes were producing the disease, is more tenable. Indeed, I have met with no well observed facts that demonstrate the power of aerial currents to transport the cholera poison even short distances. That they may do this is more an inference from the supposed nature of the poison than from any reliable observations. In cities it is difficult to trace any influence from the winds. The absence of wind has been found unfavorable. A calm and stagnant air seemed to increase the mortality. The question whether the poison can be carried any considerable distance upon the wind, is then, as yet, unsettled. In India, while the disease was advancing from its original home towards Bombay, it made its journey in the face of a monsoon blowing steadily day and night in the opposite direction. It has marched down the western shore of the Bay of Bengal in the face of the same wind, and it is reported that it advanced more rapidly in these instances than it did while moving in a direction which concurred with the course of the wind.

Search has been made to ascertain whether abundance or scantiness of rain influences the disease, and the result has been negative. Inquiries have been made to learn whether the weight of the air, as indicated by the barometer, exercises any important influence over it; the answer again is in the negative; but there can be little doubt that localities that are low and damp, grounds especially that are not susceptible of drainage, independently of removable filth, are more exposed to cholera than dryer sites, although many such undrained grounds escape entirely. There is a general concurrence in the opinion that the regions where fever and ague prevails, are the regions least likely to escape the cholera, other things being equal. It is a general belief that just those circumstances which concur to render a locality especially liable to typhus and typhoid fevers will make a visit from cholera certain when it is epidemic. But Mr. Simon, whose official position will guarantee the correctness of his statement, says: "It is unquestionably true, that many habitual seats of fever were visited by cholera; on the other hand, many of the worst *fever nests* in the metropolis, London, were unaffected by it." In this connexion I may state, that repeatedly, when cholera has been epidemic at the quarantine hospital on Staten Island, it has been remarkably fatal among those who had, or were recovering from typhoid fever.

A disease having the prominent features of Asiatic cholera, and which has not been distinguished from that affection, has been often found in this city since the first epidemic in 1832. Previous to that year the word cholera, representing a disease different from cholera-morbus or cholera-infantum, does not occur in the mortuary records. Between that year and 1860 it is excluded only eleven times. In the other seventeen years of that period, with the exception of 1834, 1849, and 1854, the disease attracted no attention. People ate, and drank, and toiled as usual, and had no thought of any unusual danger to life. In 1852, the number of deaths ascribed to cholera was three hundred and seventy-four, yet the disease was considered epidemic. In 1850, there were fifty-seven deaths from the same disease; in 1853, thirty-three; in 1855, nineteen; in 1860, seventeen; in 1844, fourteen; in 1857, eleven; in 1859, 1856, 1845, and 1858, nine, eight, six, and five; in 1839 and 1840, two and one respectively. In thirteen years, from 1848 to 1860 inclusive, cholera occurred every year but one. This period included two epidemic years. Whether this sporadic disease is what is now denominated "sceptic cholera," or whether it is cholera-morbus in an aggravated form, we may not now be able to determine. If neither of these, and there is little probability that cholera arising from decomposing organic matter would be frequently mistaken for the Asiatic variety, then, relying on the correctness of these returns, the causes are sometimes strictly local, or perhaps strictly personal, when it occurs as a sporadic affection.

Having examined, as well as the time will allow, some of the principles that govern the production and spread of this disease, we turn again to the disease itself. I repeat to you that when it is epidemic, I believe it is produced by a special miasm which can be generated by zymotic or catalytic agency in any air, when certain constituents necessary to its composition are present; and that if the poison be brought to an atmosphere that does not possess those elements, the disease will affect only those who inbreathe the imported poison; and that it is not the *person* that brings the poison, but the cloth-

ing, baggage, or merchandise capable of acting the part of *fomites*. Dr. Baly suggests that the poison is something adhesive, something that can attach itself to garments and baggage, and merchandise. I do not know how that may be; but all similar poisons remain for a time apparently inactive in the system, after their entrance into the body. Then the question comes, how long is the period of incubation? How long does the poison remain in the system before it manifests itself in symptoms? You have already some data upon which to answer this question. You remember the account given by Dr. Houston of the physician who came to Wheeling during the prevalence of cholera in that city, and returning towards his home the same day, reached a healthy village at night, and ten hours from exposure was attacked, and died the next day. This seems to imply that the period of incubation may frequently be very short. Dr. Baly refers to twelve analogous cases—that is, instances in which persons have spent a day or a few hours in infected places, and were afterwards attacked. "In all these, the interval between the exposure to infection and the attack was under six days, and in one-half of them it was under three days." The German authorities speak of a case which they regard as authentic, in which the period from the exposure to the manifestations of the disease, was twenty-one days. That the period is often very short, only a few hours, is shown by a variety of facts; and that its duration varies greatly, is equally shown; and what may be its utmost limit has not yet been ascertained. But there are sufficient grounds for the belief that the period does not *usually* exceed two or three days.

In regard to the time of day when the attack begins, Dr. Hutchinson deduced from facts noted by himself, that the larger number were seized during the morning hours. Thus in seventy-nine cases, fifty-five were attacked between 1 A.M. and 12 M., and twenty-four between 1 P.M. and 12 at night. Of the fifty-five morning attacks, ten, or two and a half the hour, occurred between midnight and 4 A.M., while forty-five, or five and five-eighths per hour, occurred between 5 A.M. and 12 M. It would seem, then, from this report, that the period of greatest liability to attack, not of diarrhœa, but of cholera symptoms, is between four in the morning and noon. Dr. Hutchinson recorded also the time of death in some of his cases. Of seventy-three persons, twenty-seven died between one in the morning and noon; forty-six between noon and midnight. The same observer notes also the duration of the disease in certain of his cases. He found, for example, in forty-one cases not fatal, that the average duration was 54.83 hours, or about two days and seven hours. The shortest case was sixteen hours, and the longest one fourteen days; the latter doubtless having some complications. Of fifty-three fatal cases, the average duration was forty-eight hours; the shortest case was four hours, and the longest one seventeen days.

Ozone and Antozone.—The theory that ozone and antozone are two opposite electrical states of oxygen, and that ordinary oxygen is composed of the two opponents balancing each other, has led to the theory that all matter is in this condition, and several important observations have been made which go to sustain the view.

The State Woman's Hospital.—The corner-stone of this institution was laid with appropriate ceremony by Mr. J. W. Beekman, May 23d, at 3 P.M. Addresses were delivered by Messrs. Beekman, E. C. Benedict, and Erastus Brooks, to a well pleased audience.

Progress of Medical Science.

Rhigolene.—Dr. Henry J. Bigelow (*Boston Medical and Surgical Journal*) has given the name Rhigolene (ριγος, extreme cold) as a convenient one to designate a petroleum naphtha boiling at 70° F. It is a hydrocarbon, wholly destitute of oxygen, and is the lightest of all known liquids, having a specific gravity of .0625. It occurred to Dr. Bigelow, on hearing of the experiments of Mr. Richardson, of London, that this hydrocarbon might be more sure to congeal the tissues than the ether now commonly used. He accordingly had it manufactured, and on trial with the "spray-producer," the agent depressed the mercury to 19° below zero, and froze the skin hard in five or ten seconds. He does not think Richardson's instrument necessary for its use, and says:

"I have for convenience used a glass phial, through the cork of which passes a metal tube for the fluid, the air-tube being outside, and bent at its extremity so as to meet the fluid-tube at right angles, at some distance from the neck of the bottle. Air is not admitted to the bottle, as in Mr. Richardson's apparatus, the vapor of the rhigolene generated by the warmth of the hand applied externally being sufficient to prevent a vacuum and to insure its free delivery; 15° below zero is easily produced by this apparatus. The bottle, when not in use, should be kept tightly corked, a precaution by no means superfluous, as the liquid readily loses its more volatile parts by evaporation, leaving a denser and consequently less efficient residue. In this, and in several more expensive forms of apparatus in metal, both with and without the concentric tubes, I have found the sizes of 72 and 78 of Stubs's steel wire-gauge to work well for the air and fluid orifices respectively; and it may be added that metal points reduced to sharp edges are preferable to glass, which, by its non-conducting properties, allows the orifices to become obstructed by frozen aqueous vapor. Freezing by rhigolene is far more sure than by ether, as suggested by Mr. Richardson, inasmuch as common ether, boiling only at about 96° instead of 70°, often fails to produce an adequate degree of cold. The rhigolene is more convenient and more easily controlled than the freezing mixtures hitherto employed. Being quick in its action, inexpensive, and comparatively odorless, it will supersede general or local anæsthesia by ether or chloroform for small operations and in private houses."

The Water Supply of London.—In the early time, even of our metropolis, there was no lack of good waters and little labor in getting it. A few famous springs, conduits, or pumps, and best of all, the great and then unpolluted river, yielded vastly more than Londoners could need or desire. But in the course of years our rapidly-augmenting population threatens to drink up the springs, exhaust the pumps, and diminish the very river, which forms a highway for our commerce, and has borne wealth to our enormous metropolis. We have this great and perplexing problem to solve:—How are the growing and gathering millions of inhabitants of England and Wales to be provided with a sufficient quantity of pure and soft water? We know that last year the metropolis suffered greatly in particular districts. An observant clergyman who has been conversant with the Thames for more than forty years, has always given this advice: 'Be sure that you economize the water, for there are many towns in England now growing, which appear to me to have ruin staring them

in the face, for the want of a proper supply of water.' Not only does every additional person want a certain quantity, but every additional individual tends to require more than any of his predecessors. The diffusion of care and cleanliness of body makes one man use perhaps twice as much water as any of his ancestors; and the more confidently men believe that cleanliness is next to godliness, the more ample will be their ablutions. A very short time ago the amount of water deemed necessary, per individual, was far less than at present. In the case of *Glasgow*, we find that in 1838, the quantity of water used per head per diem, over the whole population, was 26 gallons. In 1845, the quantity rose to 30 gallons per day; in 1852 it increased to 35 gallons per head in some parts of the city, and 38 in others. Now the amount delivered is 45 gallons per head per diem. The entire eight companies at present jointly pour every day into the metropolis and its immediate suburbs, on an average, not much less than 100,000,000 gallons of water. In January last, they returned their daily average delivery as 26 gallons to each person (including manufactories). If we confine our attention to the superior residences of London and its suburbs, and point to our bath-rooms and high service water arrangements as fair specimens of the improved supply of water in our day, we shall grossly deceive ourselves by selecting the very best, and ignoring the worst. The deficiency of water in many, if not most of the poorest and most thickly-peopled districts in the metropolis, is notorious, or ought to be made notorious.

The evidence of Dr. Horace Jeaffreson is thus presented (late Medical Officer to the Fever Hospital):—'Guided by my knowledge of the main centres of the typhus infection, I have lately made, as closely as it was possible for one person to do, a house-to-house inspection of the worst quarters of Lambeth, St. Giles, etc. The water supply is extremely deficient. Those houses the best supplied have each a butt, holding about 80 gallons, into which water flows from a stand-pipe, for from ten minutes to half an hour each day, and is supposed to supply the wants of twenty persons for cooking, washing persons, house, and linen, and for the rinsing down of the water-closet. At other times a larger butt, but in relation to the number of persons proportionately smaller, supplies a whole court of ten or more three-roomed houses, which have no back-yards, and a population of one hundred and fifty people—members of thirty different families. On Sundays even this supply is absent, and in many houses water for the Sunday cooking has to be borrowed. More than nine-tenths of these water-butts have no covers, and fully half are placed so as to catch the drippings from the foul eaves of the houses, and are lined internally with scum and slimy vegetation. Several two-roomed houses, containing sixty-four inhabitants, are thus supplied:—A half-inch pipe projects a few inches through the wall of the court, so that any small can or tub may be placed under it on the soppy grounds by such of the inhabitants as possess them. The water flows for twenty minutes only in the course of the day.' We fully believe that similar conditions would be found to prevail in nearly all the similar districts of London, and sometimes in places where they would not be expected. The entire metropolitan population is now 3,222,717 souls. About the commencement of the next century, it will be between 5,000,000 and 6,000,000; 220,000,000 gallons daily of water must be at our command for the future metropolis. Apart from dry seasons, there is reason to think that, from various causes, our great river is lessening in volume. Even supposing that a sufficient quantity of water could be procured from the Thames, would such water be desirable and safely drinkable? Although the Upper Thames is not so disgracefully foul as some of our other principal rivers, yet as compared with any standard of pure drinking-water it cannot be commended. A vast and increasing quantity of sewage falls into it from the adjacent towns. Gigantic efforts are being made to purify the water, but the fifty-six towns on the Upper Thames are to some extent rendering the great undertaking nugatory. They are sending their sewage into the river above its tidal influence, and fouling at one end, while the Board of Works are purifying at the other. Particularizing the several water companies in 1854, Dr. R. D. Thomson said, 'Of all these waters it may be generally premised that they were characterized by the formation of a deposit, on standing, consisting principally of vegetable organisms, mixed with abundance of animal life. The conclusion seems inevitable that the waters of the Thames, even when purified as we may expect by the most delicate and refined adaptations of modern mechanism, still retain in their chemical constitution a condition which renders them fertile creative sources of vegetable and animal life.' Dr. Hassal says, 'I entertain also the same opinion that river waters in general are very unfit for drinking purposes, and for these reasons. First, rivers are required as the common sewers of the places through which they pass, and are exposed to a great variety of sources of contamination. There is another reason—river water contains organic matter.' The conclusion of the Committee for Scientific Inquiries, in relation to the cholera epidemic in 1854, was that the waters supplied by the different metropolitan water companies, both during the period when the cholera prevailed and subsequently, 'were far from possessing the requisite purity in consequence of the large quantity of organic matter contained in them.'

One passage of the same committee's report says: 'The present state of scientific knowledge does not justify dogmatic assertions on this subject, but there are many reasons for believing, in respect not only of cholera, but of many kindred diseases, that the means and agencies of morbid infection stand in intimate relation to decaying animal products within and without the body; and the slightest taint of organic decomposition within the drinking-water of a large population therefore constitutes a danger which we cannot but regard with as much alarm as disgust.' In the visitation of London by the cholera in 1853–4, it was clearly ascertained that a very large population drinking foul water suffered from the epidemic more than three times as much as a similar population drinking clearer water.' After analysing the different schemes for supplying London with water, the writer concludes: 'Clearly, then, we cannot rely upon the great river that flows over the chalk—the Thames—nor on the great reservoir that lies under the chalk; we must go further afield; great lakes or remote rivers, or the high grounds which form the first receptacle of the waters of heaven, yielding them unpolluted to the lower levels, and feeding the great rivers. This can be obtained from mountain ranges in North Wales, from which the river Severn is supplied. It requires no particular sagacity to foresee that the satisfaction of the exigencies of London primarily, and several other important towns secondarily, will become the great engineering problem of the day. Our great consolation is, that in this sea-girt isle, and with the copious rain-fall of some of our districts, there need be no irremediable deficiency. The mountains, the lakes, the unpolluted and many minor streams, are unfailing depositories of excellent water, if only our science, our toil, and our capital, are perseveringly directed towards them.'—*Condensed from the Edinburgh Review, April*, 1866.

THE EXTENSION OF THE LECTURE TERM.

THE subject of medical education, although it must be confessed a somewhat hackneyed one, has not, by the ventilation which it has received, lost any of its importance. It still presents the most serious claims to our attention, and still invites a candid discussion of the means which should be adopted to bring about many much-needed reforms. It has been long enough conceded that if we would raise the standard of qualifications of those who are to practise our art, we should first settle the all-important question as to what shall constitute a thorough, substantial, and creditable medical education. Very much has already been said upon this subject; and although some good has been effected as the result, we are convinced that much remains to be done before the profession can satisfy itself of the fact that all the requirements of the case are duly met. Indeed, almost all are ready to acknowledge that a radical reform is now called for, and the profession are beginning to appreciate the means which should be adopted to bring about the end. In this connexion there are many matters which must in turn claim our attention. Foremost among these, and one which, perhaps, as a subject, lies at the very foundation of all reforms, is the manner in which medical instruction is now carried on in our colleges.

To discuss this matter with the fulness that it requires, would of necessity compel us to go over a good deal of ground, and would consume too much time and occupy too much space to do it justice in a single article. Leaving, however, for further comment, many other abuses in our college system, we propose at this time merely to offer a few remarks upon the importance of extending the period of our lecture seasons. The propriety of such a measure has been repeatedly considered; and although much difference of opinion on minor points has been expressed, the profession are to-day pretty well convinced of the necessity of it. The medical teachers, then, into whose hands it has now been placed for some definite action by the American Medical Association, can rest assured that any increase of time which they may recommend will be endorsed by their patrons.

We are perhaps not ready to imitate our academic schools in respect to the length of time required for study, although we are satisfied that we shall eventually have to come to it. But we cannot expect at present to make more than a beginning, and we should congratulate ourselves that such seems about being made.

Every one who has attended medical lectures appreciates the necessity of one of two things: either a decrease in the number of lectures given, or an extension of the time to profit by them. One argument that has been raised against the extension of the lecture term, is the increased outlay it would incur upon the student for living expenses. But why should not this same argument hold good with the literary seminaries, in which the vacations are short, and the term of study four years instead of three? The student taking the academic course has to submit to the regulations so far as regards the filling out of his time, or else he does not receive his degree. We are aware that many of our students may be too poor to meet even this extra demand upon their means; but to such we would offer the friendly advice to turn their attention to some other pursuit, which would sooner place them in comfortable circumstances.

If the lecture term be extended, the professor would be the gainer in increased opportunities for study and lecturing—would be able to go over more ground to more advantage to himself, and satisfaction to the student. The latter, instead of being crowded with six or seven lectures a day, would certainly be able to digest three or four.

When we contrast the present state of the student with what it might be in respect to the work allotted him, and the time spent for the performance of his tasks, we should be mortified at having this evil exist so long without the easy remedy proposed. The medical student of to-day, if he attempts at all to do his duty, performs an amount of labor, of self-denial, of almost privation, which at first sight appears incredible. We find him in the morning, for instance, punctually at the lecture at nine o'clock; he remains in attendance at the morning sessions until one P.M. An important operation is to be performed at some one of the hospitals at half-past one or two; he snatches a hasty meal, and hurries to the operating theatre, and finds that when the operation is finished, he has barely time to get to the college before the afternoon lectures commence. When these have concluded at six, we find him hurriedly walking to his boarding-place to get his supper, after which he must attend his private "quiz" at half-past seven in the evening. This generally lasts two hours, and when our student gets to his room he is expected by the exacting professors to *study* up the lectures of the day.

But, it may be asked, what time has the student for dissection? He must either be content to dissect during the holiday week, neglect other matters, or wait until after the course is finished, and pursue his anatomical studies in the spring, when the weather is warm, and when such work is peculiarly unpleasant, if not unhealthy. We are speaking now of the full-course student—of the student in his second or third year, during that part of his pupilage which is most important to him, and in which he has most need of time for study. That this picture is not overdrawn or too highly colored, can be attested by any who have availed themselves of instruction in any first-class medical college.

Let us suppose the lecture term to be increased. Can any one fail to acknowledge that the effect would be most beneficial upon the student, not only physically but mentally? Would he not then have time allotted him for studying up his text-books, following the lecturer while the lecture is still fresh in his mind; and would he not profit more by the bedside instruction offered him, than when he snatches an opportunity between times, and wearily tracks from bed to bed, with aching legs and empty stomach?

We commend to the attention of our readers the enterprise of Dr. J. M. Toner, of Washington, D. C., who proposes to issue, at as early a period as possible, a biographical dictionary of all deceased American physicians. Except Dr. Thacher's work, which presents us with a history of American Medical Institutions, besides the biographies of the earlier physicians of the country; and Dr. Williams's compilation of sketches, having for their subject the more prominent magnates of the profession, no publication of any pretensions, in this most attractive field of research, has lately appeared.

The intention on Dr. Toner's part, that the collection shall embrace some ten thousand names, will constitute a sufficient guarantee of the national character of the work, the value of which will be enhanced in proportion to the coöperation of relatives and friends of the deceased. Printed forms, we understand, will be furnished by Dr. Toner to correspondents desirous of communicating definite facts; vague, elaborate eulogies for a work of this kind, we presume, will be decidedly out of order. The enterprise deserves, and we hope will achieve, success.

In the present number we have been compelled, on account of the large quantity of material on hand, to crowd out many interesting contributions, which we hope to have an opportunity of presenting in our next. Among the articles which have been deferred, we may mention one by Dr. Brown-Séquard, one by Dr. H. R. Storer, and one by Dr. T. A. Emmet.

Reports of Societies.

AMERICAN OPHTHALMOLOGICAL SOCIETY.

THIRD ANNUAL MEETING.

The Third Annual Meeting of this Society was held in Boston on the twelfth and thirteenth of June. The first session began at the Massachusetts Eye and Ear Infirmary at nine A.M. The President of the Society, Edward Delafield, M.D., of New York, called the meeting to order, and after the minutes of the preceding meeting, held in June, 1865, in New York, had been read by the Secretary, Henry D. Noyes, M.D., the regular business of the Society was proceeded with. Dr. B. Joy Jeffries, of Boston, presented the Report of the Committee on Bibliography, which was a translation of the brochure appended to *Zehender's Monatschrift*. The Report was referred to the Committee on Publication.

Committees on nomination of officers, choice of subject for discussion, and election of new members, were appointed.

Dr. H. B. Sands, of New York, read a paper narrating a case of sudden blindness in one eye, occurring in a young medical man. The patient was in excellent general health, of good habits. He discovered a mist over the eye one morning, having a distinct recollection of having used that eye for the purpose of making a microscopic examination the evening before. After an interesting and careful account of the immediate and successive ophthalmoscopic examinations, together with the presentation of sketches of the field of vision, in the case which had now terminated in atrophy of the optic nerve, Dr. Sands concluded, although he expressed his doubts as to the perfectness of the theory, that the original morbific process was due to hæmorrhage into the sheath of the optic nerve. The paper was briefly discussed by Drs. Agnew and Noyes.

Dr. E. Dyer read a paper giving an account of the *ante* and *post-mortem* examination of *Anton Probst*, the murderer, who was hung on the Friday before the meeting. The eyes were examined fifteen minutes before the execution, by means of a kerosene lamp. Immediately after he was cut down, the same lamp, with the ophthalmoscope, failed to illuminate the eye. An electric light was then used, which gave an illumination which Dr. Dyer had never seen equalled. Both lenses were found to be fractured and the right retina detached. The eyes were very placid; the pupils, the same as before the execution, moderately dilated. There was no hæmorrhage beneath the retina. The eyes were enucleated and the ophthalmoscopic examination verified.

Dr. J. S. Hildreth read a paper entitled, "Extracts from Observations on Anæsthesia of the Cornea, and radiating Fibres of the Iris." This paper consisted of the recital of several cases in which there was complete anæsthesia of the cornea, as evinced by the want of sensation on touching it, and of the iris by its inability to dilate. These symptoms were observed in cases of pannus and ulceration of the cornea. Dr. Hildreth treated the cases by performing Hancock's operation, the so-called division of the ciliary muscle, when, as he claimed, the anæsthesia of the cornea was immediately overcome and the iris dilated.

The paper induced a spirited discussion, which was carried on by Drs. Althof, Agnew, Holmes, Noyes, and Hildreth. Dr. Althof thought the symptoms narrated were those of glaucoma, and not of any newly discovered disease. Dr. Agnew proposed that an opportunity should be afforded by Dr. Hildreth, on what he regard-

ed as a type case, for the carrying out of the procedure, so that the subject might be investigated.

The Society then went into executive session.

SECOND DAY.

The Society met in the New City Hospital. Dr. G. A. Hay read a paper and gave a demonstration in reference to the refraction of rays from a single point impinging on a plate of plain glass, as in H. Helmholtz's ophthalmometer.

Dr. Derby read a paper on a more exact method of testing the Acuteness of Vision, in which he advocated the use of a steady light in a darkened room, instead of the employment of ordinary and varying daylight.

Dr. C. R. Agnew described a new method of bringing forward the rectus internus muscle in divergent squint. The method has the advantage of not burying the cornea in the dissected tissue which is brought forward. Two threads are passed through the muscle; one is united to the conjunctiva in or over the superior rectus, the other in the same position as to the inferior rectus.

Dr. H. D. Noyes read a paper on amblyopia produced by osmic acid, and some cases of sub-retinal effusion treated by puncture of the retina, according to Graefe's method.

Dr. B. Joy Jeffries then demonstrated the anatomy of the ciliary muscle, showing that Hancock's operation did not in fact divide circular fibres of this muscle, and therefore division of this muscle had nothing to do with the cure of glaucoma; that it was the relief of tension which might also be effected by an incision into the sclerotica. Drawings showing the comparative anatomy of the muscle were also shown. Dr. Jeffries also exhibited the lenses of various fishes, horse mackerel, etc., suspended by the suspensory ligament.

The Society then took a recess till 1½ P. M., when the subject for discussion, *Cataract*, was taken up. Statistics were presented by some of the members, and general remarks on the subject of extraction were made by Drs. Agnew, Holcomb, Holmes, Hildreth, Seely, Sands, Noyes, Williams, Dix, and Allin.

It was voted to continue the subject of cataract at the next session, and to meet at Niagara Falls on the second Tuesday of June, 1867.

The following gentlemen were unanimously elected officers of the Society:

President—Edward Delafield, M.D.; *Recording Secretary*—Henry D. Noyes, M.D.; *Corresponding Secretary*—H. Althof, M.D.

The by-laws were amended so as to admit of the election of a Vice-President; when Henry W. Williams, M.D., was unanimously elected Vice-President.

The following gentlemen were elected members of the Society:

Francis Delafield, M.D., of New York; A. F. Wadsworth, M.D., of Boston; H. L. Shaw, M.D., of Boston; Charles E. Rider, M.D., Rochester, N. Y.; John Green, M.D., St. Louis, Mo.; Bolling A. Pope, M.D., Memphis, Tenn. *Honorary*—Dr. C. Schireigge, of Berlin, Prussia.

The following members of the Society were present during its Sessions:

Boston—Haskett Derby, M.D., J. H. Dix, M.D., G. A. Hay, M.D., B. Joy Jeffries, M.D., ——. Sprague, M.D., H. W. Williams, M.D., C. R. Agnew, M.D. *New York*—H. Althof, M.D., C. M. Allin, M.D., F. J. Bumstead, M.D., Edward Delafield, M.D., William F. Holcomb, M.D., Henry D. Noyes, M.D., D. B. St. John Roosa, M.D., Henry B. Sands, M.D. *Albany*—C. A. Robertson, M.D. *Philadelphia*—E. Dyer, M.D. *Baltimore*—E. G. Loring, M.D. *Chicago*—E. L. Holmes, M.D., J. S. Hildreth, M.D. *Cincinnati*——. Seely, M.D.

The members from other cities were entertained by Dr. J. H. Dix in a charming way, at a reception held at his house on Tuesday evening, where very many of the Boston notables in the profession were present. On Wednesday evening the Society, by invitation of the Boston members, Dr. B. Joy Jeffries being Chairman of the Committee of Arrangements, sat down to a grand supper at "Parker's," after which the members separated, having enjoyed both the scientific and social parts of the third meeting of the American Ophthalmological Society perhaps more than the previous meetings.

NEW YORK ACADEMY OF MEDICINE.

Special Meeting, May 30, 1866.

Dr. James Anderson, President, in the Chair.

DISINFECTANTS.

Dr. Squibb, in his report upon "Disinfectants," after a statement of his belief that cleanliness and ventilation were *the only true disinfectants*, took up the consideration of the agencies of heat, or heat and motion, in the prophylaxis of disease. The experiments of Dr. Harris, who had, in his investigation of the laws which govern the propagation of yellow fever, resorted to the steaming of vessels and scalding of infected clothing, tended to prove that these means promised favorable results; still, according to Dr. Harris's opinion, they were not extensive enough to be conclusive. After heat, he would rank chlorine as the next most efficient of the special agents. Chlorinated lime, which gives off the gaseous chlorine, was the best and cheapest deodorizer as well as disinfectant; this, fortunately, was also in popular favor and use. Common quick-lime (pulverized), charcoal (pulverized), or a mixture of the two, were beneficial under certain conditions. A good smoking followed by a good whitewashing, was excellent, since in good smoke were present more or less suspended carbon, creasote, pyroligneous acid, etc. The last-mentioned method was particularly applicable in the case of stables and other like receptacles of filth. But in all instances much depended upon proper discrimination in the selection of materials specially adapted to the end in view. He recommended finely pulverized quick-lime, and the same intimately mixed with pulverized charcoal, to be constantly on hand among the armamentarium of Sanitary Boards; these could be conveniently issued to institutions in barrels.

Dr. Sayre moved that, inasmuch as the facts adduced in the report were of vital importance, the paper be referred to the Council of the Academy for early publication. Carried.

Dr. Harris thought that the experiments made by him, as alluded to in the report, were not extensive enough to be of scientific value. Mr. Newland, under the direction of Dr. Trench, had been conducting some experiments in Liverpool on a rather large scale for the past two years, and, in the course of his investigations, had carried the point of heat up to 303 degrees. He preferred to have the subject yet more thoroughly canvassed before committing himself to any conclusion.

VENTILATION.

Dr. Griscom offered his report upon the above subject, in which he strongly supported the claims of the *Archimedian Screw-Ventilator*, as furnishing what was long a desideratum in these contrivances—*a mechanical power*. He had practically tested the utility of the invention, and was well satisfied with the operation of the principle upon which it was based.

Dr. Stone said that this matter of practical ventila-

tion had proved quite an enigma to the Metropolitan Health Board; that owing to the faulty construction of the tenement-houses, their engineer was compelled to content himself with the occasional destruction of a window-sash, and the elevation of the doors three or four inches from the floor. He would inquire of Dr. Griscom, whether or not these ventilators were capable of being satisfactorily adapted to any aperture in a roof.

Dr. Griscom replied that he had one of these screw-ventilators adjusted to the roof of his own dwelling, in a position calculated to thoroughly test its value, and it had given ample satisfaction. A single puff of wind was all that was requisite to set the flanges in motion.

Dr. Squibb was of the opinion that the practical solution of the difficult problems as to *the when* and *the where* of the application of remedies for bad ventilation belonged to the engineers. As far as he understood the operation of the principle governing this *Archimedian Screw-Ventilator*, he thought there was a partial loss of power, and that to this charge *Espy's* and *Emerson's* ventilators were not liable. Any of them might give satisfaction for a time; but for his part, he did not favor any action of the Academy looking to an endorsement of these patented inventions, if for no other reason, on account of their tendency to assume their places among "the things that were."

Dr. Sayre referred to a meeting of physicians called at his instance, when a member of the old Health Board, convened for the discussion of this subject. He then demonstrated a plan by which currents of air might be mixed through the medium of a diaphragm.

Dr. Stone was of the impression that this principle, as applied in the case of the Park Bank in this city, had been tested and found to have been ineffectual.

Dr. Hamilton had found a certain contrivance very beautiful in theory; and when in charge of the Central Park hospital, had it, at a cost of five hundred dollars, applied to the chapel, which was held to be a model building for the purpose. It proved a complete failure. He was therefore opposed to hasty conclusions in matters of this kind.

Dr. Sayre thought that the present Health Board had facilities for testing these inventions which had never been enjoyed by any previous body; he would therefore suggest that the same be referred to them, for the purpose of being practically tested.

Dr. Stone replied that this idea of ample power was a popular error; that in thrusting these inventions, etc., upon property holders, the Board could be made legally liable for damages, and the cost of alterations in the event of a failure. The inquiry, "*Who will pay the bill?*" would everywhere greet them.

Dr. Griscom, in reply to Dr. Squibb, averred, that in *Espy's* ventilator the wind was received in but *one* direction; whereas in the invention recommended in his report, it was made available from *all* quarters. The *Archimedian Screw-Ventilator* had freed large manufactories of the vapor of steam, which had before rendered it difficult to distinguish objects at a reasonable distance from the observer; had caused steam to ascend from a pipe in a perpendicular line during conditions of the atmosphere in which the opposite condition had always been known; had readily drawn up newspapers with a string attached; and, notwithstanding theories, had been found capable of being turned by reflected wind. *Mott's* ventilator was constructed upon the principle of the circulation of the blood, and was a success as far as it went; but we needed something more, which has been here supplied, to wit, a mechanical power to lift up and carry forward. It was no part of his intention to seek the endorsement of the Academy for the invention; he merely aimed to present the principle in its proper bearings, and to stimulate investigations in a most interesting quarter.

The Academy then adjourned.

Stated Meeting, June 6, 1866.

Dr. James Anderson, President, in the Chair.

Dr. Sayre, after the reading of the minutes of a previous meeting, moved a reconsideration of Dr. Post's resolution, endorsing the Board of Health. He apprehended that the Academy might be subjected to ethical discipline by the American Medical Association for a violation of their code, in that the Board of Health had recognised in its appointments the claims of "homœopathy."

Dr. Harris, on the part of the Board, disclaimed any sympathy with the system in question; in fact, all the medical members thereof had protested against the act. As it was, however, the adherents of this system had so small a chance for managing matters to their liking, that they have as a body protested.

Dr. Sayre replied, that in the debate before the Board, as reported by the public prints, in regard to this question, Dr. Parker "could see no merit whatever in the homœopathic treatment;", and Dr. Stone in the same connexion, while acknowledging the unsatisfactory results of said treatment as tested at Vienna, was yet willing to concede somewhat to popular prejudices; in other words, he condemned individually what he was ready to allow officially. For his part, he contended that an endorser was equally responsible with the drawer of a note, and that the precepts of the school in which he had been educated were adverse to the adoption of a similar line of action. At all events, the claims of the parties in question had somehow been acknowledged in the appointments soon after made, and it was incumbent upon the Academy to refrain from even an indirect recognition of that procedure.

Dr. Raphael, as a matter of courtesy to the original mover of the resolution, who was not then present, offered an amendment to lay the whole subject on the table, which was carried.

Dr. Ephraim Cutter, of Boston, exhibited in his own person the action of the laryngeal apparatus in vocalization, etc., bringing into view the orifice of the Eustachian tube, the posterior nares, etc. He also presented to the notice of the Academy a spray-producer for procuring local anæsthesia, which was constructed of tin, and essentially consisted of the extremities of two oil fillers, adjusted at right angles to each other. He likewise introduced a contrivance combining the requisites of a blowpipe and a spray-producer, simple in construction, and not liable soon to get out of repair. This could be made of either platinum or silver, and was ornamental as well as exceedingly durable.

Dr. Squibb notified the Academy that he had on hand for distribution 600 lbs. of the Disinfecting Powder mentioned in his late paper, and that it was contained in two barrels subject to the order of the Academy.

Dr. Sayre moved that one barrel be sent to Bellevue Hospital, and the other to the Board of Health. Carried.

Discussion on Quarantine.

Dr. Harris read a paper as above, in which he advanced the view that quarantine had no influence in preventing the introduction of the cholera, and that the only requisite was an effectual purification of those who had been exposed to the disease. He claimed that merchandise, as such, had never carried the pestilence;

that the greatest danger arose from clothing soiled by the fermenting albuminous discharges, and that every resource should be brought to bear to absolutely disinfect all such material.

Dr. Bibbins pronounced the quarantine as at present conducted a national disgrace, and one which no monarchy would for a moment tolerate. He was no advocate for half-way measures; he did not believe in intensifying the virus by huddling masses of humanity together. The secular papers had taken precedence of the profession in agitating the matter by an exposure of the attendant abuses. He charged that the Metropolitan Board of Health, created by the Legislature and backed by a Congress identical with it in sentiment, might do more than they had done. He held this Academy, the profession, nay himself, responsible for not having cast the weight of their influence collectively and individually against this crying evil.

Dr. Sayre desired to absolve himself of any responsibility for the present condition of things, since he had unavailingly been agitating a reform for the past six years.

Dr. Bell declared the law to have been at fault from the very start; as far back as eight years ago the subject of quarantine reforms had been introduced before the Legislature, but by the manipulations of politicians all essential provisions in the bills had been stricken out, and in lieu of reform the people had been treated to enactments in which indefinite *discretionary* powers had been conferred. The Board, he was authoritatively informed, had just seized Seguin's Point, and now the old question of buildings would of course come up. But why talk of these, when in tents, which may be had in almost unlimited quantity, and which could be pitched in a very short time, every sanitary requisite was attainable? He very much questioned whether reforms were practicable as long as officers found it to their interest to detain emigrants at quarantine. We may talk of partial quarantines; but are we free from blame when our vessels leave port in a condition just as filthy and with equally bad provisions for ventilation as those arriving from abroad.

A further discussion of the subject was then, on motion of Dr. Sayre, postponed until the next meeting, after which an adjournment was declared.

EAST RIVER MEDICAL ASSOCIATION.

Stated Meeting, June 5, 1866.

Dr. John Hart, President, in the Chair.

DISCUSSION ON CHRONIC DYSENTERY.

Dr. Priestley opened the discussion by the reading of a paper and the exhibition of several colored diagrams, executed by himself after post-mortem specimens, which illustrated the lesions belonging to this subject. He contended that *chronic diarrhœa*, a term very loosely applied, was in reality a disease of rare occurrence, and belonged, if at all, to the history of enteritis, arising in the course of a typhoid fever. It can but seldom be originated from acute diarrhœa, since the patient survives the attack by recovery from enteritis; but if, on the contrary, the derangement of the alimentary canal is continued, the disease becomes merged into a dysentery of the acute or chronic form. In a certain number of the fatal cases which came under his charge while on duty at David's Island—and these were from other hospitals with cards accredited as chronic diarrhœa—he had made very minute autopsical examinations, and as a rule found the lesions those of marasmus and chronic dysentery. Only in two instances did the small intestines show anything more than a slight congestive redness. None of these patients had large serous stools, but all upon admission were suffering from frequent tenesmus and small, slimy evacuations mixed with a muco-purulent effusion. He had also frequently found a large highly congested liver, with the posterior lobe considerably thickened. He might venture the theory that the return circulation of the portal vessels thus interrupted, might indirectly add much to the morbid changes discoverable in the lower twelve inches of the colon. He had also made many autopsies at David's Island of cases of reputed typhoid fever, and generally found the lesions those of chronic dysentery. Patients would be admitted into the various military hospitals laboring under no specific disease, but broken down by exposure, by prison-hardships, change of diet, habits, climate, etc., etc.; in fact, in a condition known to the army surgeon as that of "general debility," with a scorbutic element superadded. The patients easily appealed to the sympathy of the ladies attached to the extra-diet kitchens, by whom many delicacies were at times furnished with mistaken kindness, patronized the sutler, and generally consumed in one day articles digestible and indigestible enough to feed them well for half the week. During all this time, too, they would be visiting the water-closets about thrice daily; some would die suddenly of an acute diarrhœa, but a majority would linger on with a chronic dysentery, proving by the lesions in the fatal cases the correctness of the diagnosis. He remembered a suddenly fatal case where the whole alimentary canal was found impacted with crude, half-digested materials, while the lining membrane of the organ was adjudged quite normal, and the other viscera, after a careful examination, pronounced healthy. The only conclusion arrived at was that death was due to simple over-feeding, to which result, perhaps, a shock of the nervous sympathetic centres, induced by a pressure of the encased mass, contributed by their reflex action upon the diaphragm. He would not, however, deny that some of these chronic dysenteric cases might not have been in their inception complicated with the lesions belonging to typhoid fever, bilious diarrhœa, and certain forms of cholera; but he maintained that these were not *per se* of long continance.

After detailing the particulars of several cases in which very thorough dissections had been made soon after death, and upon which he based his view, he passed to the consideration of the treatment.

The extensive lesions of the colon in the aggravated cases, together with the enlarged and altered condition of the mesenteric glands, were certainly not very stimulating to our faith in any plan of treatment. We must therefore be prepared to hear of a great many recommended remedies. As aliment, beef-tea, poultry, eggs in various combinations, milk-punch, and liberal rations of Bourbon whiskey or sherry wine, were generally adopted.

He relied in a measure upon the *Subnit. Bismuth* in combination with the *Pulv. Ipecac. Comp.*, or a somewhat similar preparation in the form of a pill, composed of the *Subnit. Bismuth and Pulv. Opii*, worked into a mass through the medium of the *Ext. Gentian.* The *Tinct. Calumbæ*, the *Tinct. Cinchon. Comp.* when attainable, and the *Tinct. Ferri Muriat.*, he had also found beneficial.

Ipecacuanha had also been highly extolled for its action in this disease. Dr. Docker, of the Seventh Fusiliers, in his experience at Madras, pronounces it to have been invaluable, but his cases were probably not as severe as those met with during the late war, and were more tropical in their character. This gentleman had given as high as ninety grains. Dr. Cunningham, of the

Fourth Bengal Europeans, who administered this drug according to the urgency of the symptoms in doses varying from a scruple to half a drachm, applied a sinapism over the epigastrium, and gave thirty drops of the *Tinct. Opii* to aid its retention by the stomach. This plan, according to his experience, allayed the tenesmus and stopped the dysenteric stools for twelve hours, while a few repeated doses cured the disease. Dr. Cunningham's theory of the rationale of this mode of treatment, and in this he agreed with him, is that the ipecac. excites extensive secretions from the mucous membranes of the intestines; overcomes, by the resulting nausea, the spasmodic action of their muscular coat; and by the lubrication of any scybalæ retained in the saccules of the colon facilitates their discharge. Besides this, enough of the drug is retained to produce a copious catharsis.

Dr. Gairdner, of Edinburgh, has essayed creasote injections, but charged the specimens used with a loss of power; he then administered it *per orem*, and believed that by its efficiency in causing the retention of ipecac. previously administered, his patients were saved,

Assistant Surgeon Oliver, of the First Battalion, Sixtieth Rifles, had succeeded in arresting the disease by combining with anodynes *Bismuth, Creasote*, and *Bals. Copaibæ*. Dr. Innes of the same regiment was in the habit of relieving the tenesmus by enemas of *Creasote* and *Tinct. Opii*, combined with mineral astringents.

For his own part, he had treated this distressing symptom, after the failure of other remedies, by enemata of the *Decoct. Querc. Alb.* in combination with *Battley's Solution of Opium*. After the subsidence of the tenesmus and the establishment of fluid or feculent stools he administered the *Mass. Hydrarg.* with the *Ol. Ricini* and the *Syr. Rhei Comp.*

Dr. H. S. Hewit, late Medical Director of the Department of the Cumberland, has advocated the treatment by *Epsom salts*, which was an excellent derivative, and probably tended to cure by inducing fluid discharges. His own experience in its use was limited.

He preferred vegetable to mineral tonics, because they could be more persistently employed, and had considerable faith in the potency of *Dover's Powder;* but many of the specimens found in the shops were comparatively valueless, owing to the use of the *Sulph. Potass.* in powder, instead of in crystal, by which latter form the minute division and consequent efficiency of the *opium* and the *ipecac* were effected.

Dr. John Shrady acknowledged that some of the diagnoses in the class of cases alluded to by Dr. Priestley had been rather loosely made, and that, owing to certain defects in the construction of the tabulated forms for reporting cases as they occurred, a diagnosis could not be readily changed except by a new entry. Hence the bed-cards did not always represent the present condition of the patient. The confusion attending the use of the terms, "chronic diarrhœa" and "chronic dysentery," appears also to have been appreciated at the Surgeon-General's office, since in a recent circular the two diseases are discussed in conjunction. He had noticed in many of the autopsies evidences of renal disease; and the direct cause of death, in some instances, was uræmia. As far as remedies were concerned, he had seen nearly all tried. Some surgeons relied upon *Hope's Mixture*, some upon a combination of the *Sulph. Morphia* and the *Sal Rochelle* dissolved in the *Aqua Camphoræ*, while others pushed the *morphine* to narcotism. *Quinine* and *Dover's Powder* was also a combination which had passed into a proverb even among the soldiers themselves. *Pulv. Opii* and *Subnit. Bismuth*, combined, had likewise many advocates, not to mention *opium* with the most powerfully styptic *salts of iron*, or with the *diacetate of lead*. Injections had been fairly tested, but in spite of the efforts of all, a certain proportion of the cases would die, while others would return to duty after having been subjected to dietetic and climatic influences under more favorable circumstances.

Dr. Burke, in his treatment of a few discharged soldiers, had resorted with benefit to a somewhat familiar combination of the *Ext. Hæmatoxylon* with *Tinct. Opii*, suspended in some convenient menstrua and administered every two hours. The treatment by *Sulph. Magnesia* was in reality the revival of an old method, which had fallen into disuse long before the war. Its merits had been discussed in some of the earlier English works upon practice.

Dr. Buttles was not familiar with the use of this agent in *chronic* dysentery, but had seen remarkable effects following its exhibition in the *acute* form of the disease. It was in the latter cases quite frequently used with marked success by Dr. Thayer, of Keene, New Hampshire.

Dr. Hart had frequently resorted to the use of the *Oleum Terebinth.*, and had found it excellent, when externally applied, for relieving the tenderness experienced by the patient along the course of the colon. He had also administered it internally in combination with the *Oleum Ricini*, with some benefit in cases which had not yet become chronic.

Dr. T. Nichols thought that, inasmuch as was well shown in the diagrams before the Association, there were in these cases inflammations, ulcerations, etc., of the colon, the topical application of remedies by means of enemata ought to be more effectual than they had proved. He would, however, give the *Nit. Argenti* a fair trial before yielding up his faith in its efficacy. Solutions of different strengths might be resorted to, although he was aware of the difficulty attending upon the attempt to apply the dissolved escharotic at the precise locality most needed. Some practitioners had endowed this agent with considerable virtue, when taken internally in the form of pill, combined with opium; but owing to its liability to produce *argeria*, it had not found many advocates.

Dr. Burke adverted to a well known instance of Argeria caused by the continuation of a prescription on the patient's own responsibility. These were pills containing nitrate of silver which had been ordered for a certain form of dyspepsia, and the characteristic discoloration took place after a few months' use.

Dr. Buttles was of the opinion that similar effects were not likely to be produced when this salt of silver was introduced *per rectum*. He had also seen it stated that some of the physicians on the continent guarded against this danger by a careful exclusion from the light while the medicine was in process of administration.

Dr. J. W. Sheppard urged the claims of the *pernitrate of iron*, which was highly extolled by Dr. Neligan. He had derived some benefit from its exhibition, and was disposed, when opportunity offered, to put it on still further trial.

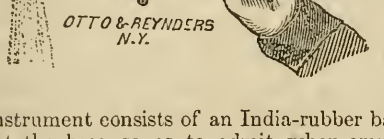
The meeting then adjourned.

Trichiniasis.—It is stated that the pigs of Hungary have long been affected with trichinæ. The disease has not been communicated in that region for the reason that the trichinous pork is not used for food. The Hungarians seem to be able to recognise meat affected with this disease by the sensation it gives while being eaten of grains of sand between the teeth. Swine are cured of this disease in that country by hempseed. The symptoms by which the disease is usually recognised are the "savage propensities of the animals and their mania for gnawing wood."—*L' Union Medicale.*

New Instruments.

LARYNGEAL SPRAY PRODUCER.

When the spray producers were first introduced, and when their value in making applications directly to affected parts was appreciated, the difficulty in reference to their almost universal applicability consisted in the scattering of the spray over too large a surface. This offered a very serious interference in its application to laryngeal affections. It was found necessary, then, to make some contrivance whereby the spray, in a small volume, could be directed at will to any given, small, and isolated space. This was finally effected by an alteration in the relation of the capillary tubes to each other, as is represented in the following cut, which is that of "Maunders' Laryngeal Spray Producer."



This instrument consists of an India-rubber ball, perforated at the base, so as to admit, when emptied, of instant refilment with air; of an upper or air-tube communicating at one end with the ball, and terminating at the other in a capillary opening; of an under or medicine-tube dipping at one end into a medicine-glass, sliding upon a pin, and terminating at the other in a capillary orifice set at nearly right angles to that of the air-tube.

To use the instrument, all that is required is to slip off the small medicine-glass; fill it two-thirds full of the fluid to be broken into spray; return it to its place, having the medicine-tube immersed in it; place the point of the instrument over the larynx; cover with the thumb the perforation in the base of the ball, and with quick forcible compression, force the air out of the ball, when immediately there will be produced a vertically directed spray of the utmost fineness. The spray may, with equal care, be directed either in a straight line or at any required angle, by the adaptation of variously shaped tubes. In order to make the current continuous and the instrument more effective, Messrs. Otto & Reynders have added an extra rubber ball, as represented in some of the nebulizers previously referred to.

Dr. Semeleder, whose book was lately published in this country, physician to the Emperor of Mexico, writes to the editor of one of the Vienna medical journals in answer to some unfriendly rumors: "I would inform my dear friends and colleagues that I am quite well and contented, and cherish the hope of remaining for some time in this pleasant condition.

Mexico, 12th January, 1866."

North Western Dispensary.—This institution has recently purchased a plot of ground on Broadway, between Forty-eighth and Forty-ninth streets, extending through to Seventh avenue, at a cost of $18,500. Dr. Stephen W. Roof has been appointed one of the visiting physicians in the place of Dr. A. David Hedges, resigned.

Correspondence.

AUTOPSY OF PROBST, THE MURDERER.—MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

To the Editor of the Medical Record.

Philadelphia, June 16, 1866.

Sir:—The main events that have interested the profession in this locality during the past week have been the post-mortem examination of the body of the executed murderer Probst, and the annual meeting of the Medical Society of the State of Pennsylvania.

Probst, who, as you know, murdered the Dearing family of eight persons, suffered the penalty of his crime on Friday, 8th inst., and after his body had hung the required time (about half an hour), the corpse was transferred to Dr. Wm. H. Pancoast, Demonstrator of Anatomy in the Jefferson Medical College, who, with other medical gentlemen, members of a commission appointed for that purpose, performed a series of galvanic experiments upon the muscles, continuing until the muscular irritability was lost. No new facts were elicited. An ophthalmoscopic examination of the retina of the eye was made by means of a powerful electric light as soon as the corpse was cut down, but no image could be discovered. The body was subsequently conveyed to the college buildings, and the next day, after a preliminary dissection of the region of the neck, a public post-mortem examination was held in the amphitheatre, before a very large audience composed of men of science, morbid curiosity-seekers, and lovers of the marvellous and horrible.

As a thorough report of the entire examination will soon emanate from an official source, it will be sufficient to state here that the abnormal effect produced seemed very inadequate to the cause of death. A dark, purple furrow around the upper part of the neck marked the position of the strangling cord, except just over the parotid gland, at the spot selected for tying the knot. The sterno-cleido-mastoid muscle of the right side was ruptured transversely, and the hyoid bone was fractured in two places, and this appeared to have been the entire extent of lesion. The thyroid cartilage was intact; the arteries and veins on both sides uninjured; there was no fracture of the second vertebra, or rupture of its ligaments. There was no congestion of lungs or brain; the stomach was empty, although food had been taken but a couple of hours before the execution. The heart, liver, bladder, and other viscera were successively examined; but there was no other lesion discovered than the rupture of the sterno-cleido-mastoid muscle and the fracture of the hyoid bone. The examination was accompanied by a lecture on the subject of hanging, from Dr. Pancoast, which was listened to with a great deal of attention.

The Meeting of the Medical Society of the State of Pennsylvania was held at *Wilkesbarre*, in *Luzerne County*, on the 13th and 14th instant, and was attended by between sixty and seventy delegates. An official abstract of the transactions will be furnished for the columns of the Medical Record by Dr. Wm. B. Atkinson, the Permanent Secretary, so that it will be desirable, in this communication, only to allude to the main features of the meeting in a conversational manner.

Dr. Burr, on behalf of the delegation from the Medical Society of the State of New York, made a very pleasing address, alluding to the community of professional interest between the two State organizations

being so much in consonance with the continuity of stream, mountain, mode of life, and general enterprise, noticed in travelling through one State into the other, so that the eye could discern no line of geographical, social, or professional division.

On the night of the 13th Dr. J. Solis Cohen, of Philadelphia, delivered a brief lecture on the *Use of the Laryngoscope*, and exhibited the larynx and trachea of a patient whom he had brought with him for purposes of demonstration, and in whom can be seen the anterior portion of the trachea, its entire extent, and one or two rings of the right bronchus. The members examined the case in rotation, and expressed themselves as highly pleased with the demonstration. The case presents some interesting pathological conditions, which were exhibited at the same time, and will doubtless be communicated to your columns in a more permanent form.

Dr. King, of Pittsburg, late the Surgeon-General of the State of Pennsylvania, narrated a curious case of tubular pregnancy which had been communicated to the Alleghany County Medical Society by Dr. Davis, a full account of which will appear in the State Society's Transactions for the year. The case is briefly as follows: Fifty-four years ago a married lady became pregnant, went on to term, labor pains apparently began, but were never followed by delivery. The tumor in the abdomen remained stationary, and the lady always insisted that she had been pregnant, and wondered why she had never been delivered of her child. She died recently at the age of *eighty-two*, and on her death-bed requested that a post-mortem examination should be made to discover why she had never been delivered. The examination was made accordingly, and the tumor found to consist of a bony case, on cutting through which a well formed and perfectly preserved fœtus of full term was exposed to view. The bony envelop was half an inch thick, and in cutting through it the head of the fœtus had been severed from its body. The whole appearance was that of a recent gestation, the head was covered with hair, and the flesh and skin intact—there being no evidence of any existence of animal decomposition.

Dr. Atlee, of Philadelphia, requested the specimen for the College of Physicians of this city; and in commenting upon the length of time the tumor had been carried, was reminded of a case in which he had been invited by Dr. Jewell, of Philadelphia, to assist at the post-mortem examination of a maiden lady, of about eighty years of age, who had carried an abdominal tumor since her twentieth year. The left ovary was gone, and the hypochondriac region of that side was occupied by a large globular tumor, with extensive attachments to surrounding structures. Its walls were like those of an ovarian cyst, and it was filled with a mass of red hair and some broken-down animal matters. The hymen was imperforate, and the uterus presented no trace of impregnation; consequently the tumor was the altered ovary of that side. The case was unique, and had often been brought forward by the opponents to the operation of ovariotomy, as a proof that ovarian tumors could be safely carried to a very advanced age.

The subject of *female practitioners of medicine* was made a matter of very lively discussion, though at one time it threatened to disturb the harmony as well as the equanimity of the members. A resolution emanating from Montgomery county was offered, to rescind a resolution passed at the meeting of 1860, which declared it unprofessional to hold consultation with the professors and graduates of the Female Medical Colleges as then organized. Dr. Traill Green of Easton, Dr. Horton of Bradford county, Dr. Hiram Corson of Montgomery county, and others, discoursed most eloquently upon the increasing sphere of woman's usefulness, and in favor of encouraging females to practise medicine, providing them with regularly educated professors in good standing, recognising such college when organized on the same basis as the present regular colleges, and availing themselves of their judgment and experience afterwards; especially calling upon the delicate hand, the flexible wrist, and the delicate sympathy of sexual organization, all of which fit them preëminently for the practice of obstetrics. The principal opposition came from the Philade'phia delegation, although this delegation was divided; but with all the eloquence they could muster, they could only succeed in negativing the resolution by the trifling majority of four, the vote as recorded on the minutes showing 23 ayes against 27 nays—a pretty close vote. The lady doctors now know where their friends reside, and ought to go out in the country to practise; the majority of country physicians want them, and the city physicians generally would be glad to get rid of them. They will be well received, especially in Bradford county and in Northampton county, where some of the practitioners express themselves ready to resign all their obstetric practice.

No sooner was this motion lost than a strong attempt was made to obtain some further action which would remove the irregularity of consulting with these female practitioners. Dr. Mowry, of Alleghany City, offered a resolution to the effect that the action in the resolution adopted in 1860 was not to be understood as preventing such members of the profession as desired it from consulting with properly educated female practitioners. The discussion of this resolution occasioned a great deal of excitement and much more confusion, until finally the subject was put to sleep for a year by a compromise in the adoption of a resolution requesting action on the subject from all the County Medical Societies, so as to secure a general expression of opinion previous to its safe delivery or abortion, at the meeting next year at Pittsburgh.

A resolution was adopted, censuring the professors of the Medical Colleges of Philadelphia for their apathy in the matter of County, State, and National Medical Organizations, and calling upon the American Medical Association for such legislation as will exclude from membership to that body any delegate from a hospital, college, or other medical organization, who was not at the same time a member of a County Medical Society. The resolution also recommended the practitioners of the State to send their students elsewhere than to the Philadelphia Colleges. As no professor or representative of the Colleges was present at the meeting, there was no opposition to the resolution, and it was carried without a vote in the negative.

The subject of *Specialties* was brought up by a gentleman from this city, resulting in the negativing of a resolution to "encourage the study and practice of specialties by properly qualified scientific practitioners." At some future day this record will be deemed a blot upon the transactions. The principal opposition to this measure came from Philadelphia; and the gentleman who offered the resolution, finding himself unsupported in the contest, gracefully withdrew, prudently reserving his strength for a future occasion.

The Treasurer handled some of the delinquent Societies pretty roughly, but in such a good-humored and diplomatic manner as elicited the approbation of all concerned, while it gave rise to a good deal of merriment.

The meeting, taking all in all, was quite harmonious and very agreeable. The members were escorted to several neighboring points of interest, and were entertained at an elegant dinner, which was got up in metropolitan style at the Wyoming Valley House.

The members are under peculiar obligations to Dr. Edward R. Mayer of Wilkesbarre for his unremitting attentions, night and day; as also to Drs. Dennis and Urquhart, as well as the other gentlemen of the Committee of Arrangements, for their kind reception and successful efforts to render the visit agreeable and instructive.

Yours truly,
C. J.

THE MASSACHUSETTS MEDICAL SOCIETY, Etc.

Boston, June, 1866.

To the Editor of the Medical Record.

Sir:—I send you a pen-and-ink sketch of some of the doings of the medical fraternity in Boston the past month. I am not one of those who think our city the "hub of the universe," or the inhabitants thereof entirely faultless in their opinions, the *Boston Medical and Surgical Journal* not excepted, *vide* issue of May 3, as regards defects of the American Medical Association, etc. But to business. At the meeting of the Suffolk District Society last month, Dr. J. B. Upham exhibited to the members present the instrument called the sphygmograph, invented by Dr. Marey of Paris, and at the same time gave a brief history of the invention and the affections in which it has been mostly used; also diagrams of cases at the City Hospital, in which he used the instrument satisfactorily on patients with different diseases, reporting one very marked case of its value in aortic aneurism. It is thought this instrument will eventually take its place among the recognised means of medical investigation. Dr. U. also took the record of the normal pulse on some of the gentlemen present, showing the method of its application.

The annual meeting of the Massachusetts Medical Society was held at the Lowell Institute, on Tuesday and Wednesday, May 29 and 30, and on the whole was a success. The exercises of the first day consisted of visits to the Mass. General and City Hospitals, where operations were performed, after which portions of papers were read at the Institute: On the Vegetable Parasites of the Human Skin, by James C. White, M.D.; Autumnal Catarrh, by Morrill Wyman, M.D.; Luxations of the Shoulder-Joint, by Richard M. Hodges, M.D.; Observations on the Physiology of the Larynx, by Henry K. Oliver, M.D.; Observations on Cholera, by Walter Channing, M.D.; The Policy or Impolicy of removing Leucocythemic Glandular Tumors, by David W. Cheever, M.D.; Cystic Tumors of the Jaw, by J. Mason Warren, M.D.; Conservative Measures required in certain Diseases of the Eye, by H. W. Williams, M.D. Dr. Henry J. Bigelow exhibited the new agent for local anæsthesia, rhigolene, and explained the ready method of its application. Dr. H. R. Storer exhibited a new clamp for the revoval of ovarian and uterine tumors in place of the écraseur, and explained in a very satisfactory manner its application and uses

The time of the second day was occupied by reading the record of the last annual meeting by the Secretary, and the annual report of Dr. Francis Minot, the Treasurer. The report of the Councillors of officers elected for the ensuing year was then read: For President, Dr. Henry C. Perkins, of Newburyport; Vice-President, Dr. Foster Hooper, of Fall River; Corresponding Secretary, Dr. C. D. Homans, of Boston; Recording Secretary, Dr. D. W. Cheever, of Boston; Treasurer, Dr. Francis Minot, of Boston; Librarian, Dr. J. C. White, of Boston; Orator, Dr. H. P. Wakefield, of South Reading; Anniversary Chairman, Dr. H. W. Williams, of Boston.

It was also voted to hold the next annual meeting in this city on the first Wednesday in June instead of the last Wednesday in May. Papers were then read by Dr. Luther Parks, Jr., of Boston, on Cerebro-Spinal Meningitis; Dr. E. Cutter, of Woburn, on Atomization and Fracture Beds; and Dr. Chapin, of Winchester, on the Medicinal Qualities of the Common Mullein.

Dr. H. R. Storer, of Boston, then read a valuable paper on the Abetment of Criminal Abortion by Medical Men, taking the ground that any measures either of omission or commission upon the part of the profession that tend to perpetuate or increase the too common impression of the community, that the fœtus is not alive before birth, should be deprecated. Putting aside any question as to the morality of inducing unnecessary abortion, there can be no doubt that to this cause, and to the almost universal adoption of methods to prevent pregnancy, much of the ill-health of our women is to be attributed, and no treatment can hope to be successful that does not strike at the very root of the whole matter. Dr. S. commented upon the failure of the Massachusetts Medical Society to respond to the call made upon State societies several years ago by the American Medical Association, with reference to obtaining proper legislative enactments regarding criminal abortions, and showed that the Massachusetts statutes were at the present time practically inoperative. The action taken by the New York State Society, at the time referred to, was quoted, and the resolutions passed by the two societies were read and compared, the preference being decidedly in favor of the sister State. Dr. S. claimed that inquiries like the present were alike appropriate, philosophical, and necessary. These matters, and all others pertaining to the sexual relations, lie at the very foundation of society. To ignore them is to allow the growth often of terrible destructive evils. Abroad, many of the most influential members of the profession were turning their attention in this direction, and with ourselves the importance of the matter is becoming generally acknowledged.

Dr. Storer's paper was to the point, convincingly argued, and evidently carefully prepared. At its close, remarks warmly commendatory were made by Dr. Corliss, one of the delegates from the New York State Society, and the unanimous thanks of the members present were voted to Dr. Storer.

After the transaction of business of minor importance, the annual oration was delivered by Dr. George C. Shattuck, on "Professional Relations." The discourse was an able production, upholding the dignity of the profession, touching upon quackery in all its forms, calling upon medical men under all circumstances to stand by the true physician, eulogizing those members who during the past year have gone to their long home, and in general terms giving advice to both old and young. The thanks of the Society were voted, after which an adjournment was made to the Music Hall, to partake of the anniversary dinner. Dr. Wm. E. Townsend presided, and after discussing the quality of the solids and fluids, remarks were made by Dr. Shattuck, Dr. Gould, Bishop Eastburn, and Dr. Jacob Bigelow. A letter in reply to a toast complimentary to the State of Massachusetts and its Governor was then read from Surgeon-General Wm. J. Dale, thanking the Society for an invitation to attend, and regretting inability, etc. The next regular toast was one complimentary to the American Medical Association, responded to by Dr. D. Humphrey Storer, and it would have done your soul good, Mr. Editor, to have heard the response; so truthful, so eulogistic, and so cutting upon those mem-

bers who have spoken lightly of that time-honored institution. Dr. Storer referred in scathing terms to the paucity of members from our State at the last meeting held at Baltimore, and stated that he had no words but of pity for those members of the profession who would ignore that glorious Association. Made up as it was by members from all parts of the country of acknowledged medical worth and science, it would stand as firm as the rock of Gibraltar, and no "clique" or "power" could move it. It was a noble tribute to the "American Medical Association," and worthy of its defender.

Dr. Hart, of New York, returned the thanks of the New York State Medical Society for the kindness and urbanity with which their delegation had been received, and desired that a large delegation might be annually sent from the Massachusetts Medical to the New York Society, when every courtesy would be shown.

The Society then adjourned, and everything passed off in a pleasant manner.

I have thus, Mr. Editor, in a hurried manner, given you a succinct account of the doings of the Massachusetts Medical Society, and trust I have not wearied your readers or yourself by too lengthy an account.

Last Friday night, June 8, Dr. Charles H. Stedman died, aged sixty-one years. Dr. S. was well known by many New York physicians, and was a man highly respected in his profession. He was a graduate of the Class of 1828 at Harvard College; was appointed Surgeon and Superintendent of the U. S. Marine Hospital at Chelsea, Mass.; subsequently Physician and Superintendent of the City Lunatic Hospital, at South Boston; and at his decease was one of the Visiting Surgeons of the new City Hospital. In the years 1855, 1856, and 1857 he held offices of trust, as Massachusetts State Senator, also Councillor, since which time he has devoted himself assiduously to his profession. His heart was ever open to the poor, and his sudden death will be mourned by a large circle of friends, professional and public. On Sunday a post-mortem was made by Dr. C. Ellis, and in addition, the following physicians were present: Drs. Ainsworth, Swan, Page, Reed, Clark, Ingals, and Ordway. The result proved that the immediate cause was rupture of the heart, from "fatty degeneration." Dr. S. had expressed the opinion at several times in his life that he had organic disease of the heart, but on examination by different physicians had been assured that no trace of disease of that organ could be discovered. The singularity of this examination has demonstrated almost to a certainty that it may be possible that this disease has continued for a period of thirty years (the time Dr. S. had complained of his trouble) without symptoms except of pain. Dr. Ellis gave as his opinion that, from the general appearance of the organ and also in fatty heart, you would get no other symptom except pain in many cases. The appearance of the heart at its apex was very singular, as if a pistol-ball had gone through it, and also the internal hæmorrhage, amounting to some six or eight ounces. The feel of the organ between the thumb and forefinger was pulpy, and it could be broken with the least possible pressure. Dr. S. attended to his duties two days before death, and was not considered dangerously ill two hours before his death. Altogether it is a remarkable case and worthy of consideration. But he has gone—a faithful and good physician.

Yours truly,

B.

James Ferguson, M.D., a graduate of the College of Physicians and Surgeons, died Tuesday, May 22.

Obituary.

PROF. E. D. FENNER, M.D.,

NEW ORLEANS.

Died, on the 4th of May, 1866, in the City of New Orleans, in the sixtieth year of his age, Erasmus Darwin Fenner, M.D., Dean of the Faculty, and Professor of the Theory and Practice of Medicine in the New Orleans School of Medicine, and Senior Editor of the *Southern Journal of the Medical Sciences.*

In the death of this most estimable man, the medical profession throughout the country must recognise the loss of a most honorable and useful member, and society the loss of the truly "good physician," and a citizen valued and cherished in all the relations of private life.

Dr. Fenner was born in Franklin County, North Carolina, of Irish parentage of the first order, in the year 1807. His father was a physician of high standing, enjoying the confidence and long-continued patronage of a most enlightened community. In early life Erasmus emigrated with his brothers to West Tennessee. After receiving a liberal preliminary education, he studied medicine, and graduated in Pennsylvania University in the year 1830. He practised his profession most successfully in Mississippi until 1840, when he moved to the City of New Orleans. There he has lived an honored and useful man for twenty-six long years. In 1844, in conjunction with Dr. Hester, he established the *New Orleans Medical and Surgical Journal*, and most ably did he conduct it during several years. This was the first successful Southern journal south of Louisville, Kentucky. After resigning his connexion with this journal, he devoted two years to the annual issue of a volume entitled "Fenner's Southern Medical Reports," and the two volumes stand a noble monument to his professional energy and industry. For several years before the war, he was co-editor with Dr. D. W. Brickell in the conduct of the *New Orleans Medical News and Hospital Gazette.* In the spring of 1856 he, in conjunction with eight of his professional brethren, organized the Faculty of the New Orleans School of Medicine; and at the breaking out of the late war, he had the proud satisfaction of seeing this institution succeed as no other of its age had ever done in this country. In the early organization of the school, Dr. Fenner was elected Dean, and he filled the position to the hour of his death. To Dr. Fenner and his colleagues is due the credit of having inaugurated the real system of clinical instruction in this country.

Dr. F. was a prominent member of the American Medical Association, a member of the New Orleans Academy of Sciences, etc., etc.; and for the long term of his residence in New Orleans, he was a "Visiting Physician" to the Charity Hospital of that city. To make his daily visit to that great institution may be said to have become a "second nature" with him.

In truth, it may be said that the life of this good man was dedicated to his profession. He was not possessed of brilliancy, but he was *honest* and *zealous* as a writer, teacher, and practitioner, and herein we at last find the real elements of utility. Dr. F. lived for his profession, and he died "in harness." At the time of his death he had just finished a faithful course of lectures to his class—deeming it his first great duty, at the close of the war, to reëstablish the school over which he presided. His numerous pupils will bear ample testimony to his industry and good faith. He had, also, just established a new journal (*Southern Journal of the Medical Sciences*), on the pages of which may be found his last

literary efforts. He did not live to see the first number of this journal. It came from the press on the morning of his death.

A "good physician," a valuable teacher, an ornament to society, has passed away; but his noble example is imperishable, and his memory will long be cherished.

Medical News.

Personal.

Rev. Dyer Ball, M.D., missionary of the American Board, died at Canton, China, March 27, 1866. He was born in West Boyleston, Mass., June 3, 1796, graduated at Union College in 1826, embarked for Singapore May 15, 1838, and went to Canton in 1845.

Prof. Wm. H. Van Buren has resigned as Consulting Surgeon of the Charity Hospital, but still continues his relations to Bellevue Hospital. Dr. E. Schilling has been appointed to fill the vacancy occasioned by the death of Dr. Cox, late Consulting Physician to the Emigrants' Hospital, Ward's Island.

PROGRESS OF THE CHOLERA.

The Steamship Helvetia, after a quarantine of some twenty-seven days at Liverpool, again set sail for this port, May 29th, and arrived here early on the morning of the 11th ultimo. This last voyage, according to the affidavits of the medical officers and other evidence, has been quite healthy. It is proper to state that seven hundred of the passengers, who had originally embarked in the Helvetia, were re-transferred from the hulks in which they had spent their quarantine, only after a thorough inspection by British officials, and a new refit of bedding and blankets.

Quarantine, N. Y.—There are now six hospital ships on duty in the Lower Bay, but their somewhat crowded condition will soon be remedied by the transfer of the passengers who have been exposed to, but who have not as yet been attacked by the epidemic, to the grounds at Seguin's Point. The epidemic itself is verging to a decline. Since our last announcement, it has been determined that measures having in view purification merely, are to be adopted at this locality. The buildings and necessary arrangements for disinfection by steam, and for supplying water from the wells in the vicinity, have been reported complete. Much opposition, which has chiefly found vent in a large mass-meeting on the 12th ult., has been manifested on the part of Staten Island inhabitants, but no apprehensions are entertained of any violent outbreak.

New York City.—According to Dr. Harris's mortuary report, six deaths from cholera occurred during the week ending Saturday the 16th ult. Additional cases have since been reported but of those which have recovered, some do not seem to have been sufficiently decided in character to render controversy on the part of medical attendants unnecessary. The health of the city in other respects, however, is unusually good.

Baltimore, Md. — Mr. Wm. Howard, aged forty-four years, said to have contracted cholera from a room-mate in New York City, who died of it, arrived here by the train on the 16th ult., and died at one of the infirmaries on the ensuing afternoon. No other cases have come to our knowledge.

Preventive and Remedial Treatment of Epidemic Cholera.—The New York Academy of Medicine, at the meeting held June 20, 1866, adopted the following preamble and resolutions offered by Dr. E. Harris: —

Whereas, The New York Academy of Medicine has endeavored to promote among its fellows, and throughout the medical profession, a spirit of exact inquiry into the prevention and remedial treatment of epidemic cholera:

Resolved, That this Academy hereby expresses its confidence in the utility of general hygienic measures as the best means of protection against the pestilential prevalence of cholera in any locality where it makes its appearance; and that the most thorough scavenging, cleansing, and disinfection, are absolutely necessary means of averting this pestilence in the cities and populous towns of our country at the present time.

Resolved, That in the judgment of the Academy, the medical profession throughout the country should, for all practical purposes, act and advise in accordance with the hypothesis or the fact that the choleraic discharge and "rice-water" discharges of cholera patients are capable, in connexion with well known localizing conditions, of propagating the cholera poison, and that rigidly enforced precautions should be taken in every case of cholera to permanently disinfect or destroy those ejected fluids, by means of active chemical agents. Also, that with the same object in view, the strictest cleanliness of person and premises should be enforced upon all who have charge of the sick; also, that all privies, water-closets, and cesspools, should be kept thoroughly under the control of disinfectants.

Resolved, That we regard the nature and causes of cholera infection, so far as the sick or their discharges can propagate it, as being so susceptible of control that there should be no fear or hesitancy in the personal care of the sick and all that pertains to them.

Resolved, That immediate and thorough cleansing and disinfection of all persons, clothing, and things that have been exposed to the discharges or persons of the sick with cholera, constitute the chief end and object of any rational Quarantine or external sanitary police regulation against cholera.

Resolved, That for purposes here mentioned, an external sanitary police is desirable in all great maritime and river towns, but that such sanitary regulations need not seriously embarrass commercial intercourse and the interests of trade.

Resolved, That the main source of protection against epidemic cholera at the present time is to be found in the vigi-

lant and effective operation of sanitary measures, municipal, domestic, and personal.

Resolved, That the New York Academy of Medicine cordially invites the physicians of every city and village throughout our country to urge the immediate adoption of adequate measures of sanitary protection against the introduction and ravages of cholera, and that to this end we pledge to our brethren and the public the hearty and continued coöperation of this Academy.

The Bellevue Hospital Morgue.—The new wing of the Bellevue Hospital, besides embracing the hospital dead-house, the coroner's office, and inquest rooms, has been in part devoted to the purposes of a Morgue, modelled after the Parisian institution upon the banks of the Seine.

The floor is paved with neat encaustic tiles, and upon it, at a height of about five feet, are laid four marble slabs, slightly inclined towards the foot. Over the whole are suspended india-rubber hose which will eject a constant current of water upon the corpse, and thus increase, by deferring decomposition, the chances of identification for the longest possible period.

The New York Academy of Medicine.—At the stated meeting, June 20th, Drs. E. Barry Dalton, Benjamin Howard, Christopher R. McMillan, of Brooklyn, Oscar G. Smith and Dr. Robt. F. Weir were duly elected Fellows.

Stevens's Triennial Fund.—A prize fund of one thousand dollars has been established by Alexander H. Stevens, M.D., ex-President of the College of Physicians and Surgeons, New York, for the improvement of medical literature, on the following plan:—Each prize, to be awarded triennially, is to consist of the interest yielded by the principal fund during the preceding three years, and will amount to about two hundred dollars. The administration of the prize is entrusted to a commission, consisting of the President of the College of Physicians and Surgeons (*ex-officio*), the President of the Alumni Association (*ex-officio*), and the Professor of Physiology (*ex-officio*), in the same institution. The following subjects have been selected, at the request of Dr. Stevens, for the first triennial prize under this fund:—

1st. The best means of preventing death after surgical accidents. 2d. The history of improvements in the medical art, and the means by which they are attained.

The competing essays on either of the above subjects must be sent in to Dr. E. Delafield, the President of the College of Physicians and Surgeons, New York, on or before the first day of January, 1869. Each essay must be designated by a device or motto, and must be accompanied by a sealed envelope, bearing the same device or motto, and containing the name of the author. The envelope belonging to the successful essay will be opened, and the name of the author announced, at the annual commencement of the College, in March, 1869. This prize is open for universal competition.

Health of Providence.—Dr. E. M. Snow, speaking of the health of Providence, says:—"The good health of the city continues in a remarkable degree. This is shown *first*, by the small number of deaths. Notwithstanding the increase of population in the last eleven years, the number of deaths in May was eight less than the average during that period. *Second*, by the very small percentage of deaths of children. Less than twenty-one per cent. of the decedents in May were under five years of age. The percentage during the last nine years was about forty-one. There were only fourteen decedents in May under five years of age, while there were thirteen over seventy years of age. There was the remarkable number of nine decedents over eighty years of age. *Third*. The healthy condition of the city is shown by the absence of zymotic diseases during the month of May. There was not a single death from cholera infantum, diarrhœa, diphtheria, measles, scarlatina, or small-pox; and only four deaths in the city, during the whole month, from the whole list of zymotic diseases. In May, 1864, there were thirty-two, and in May, 1865, there were fifteen deaths from this class of diseases.

"There is no epidemic of any description in the city at the present time, and not the slightest indications of the epidemic tendencies which, in former years, have preceded the approach of cholera.

"It is certain that the epidemic condition of the atmosphere necessary to produce epidemic cholera does not yet exist in this country, and there is still reason to hope that it may not reach us this year."

Typhus Fever in the District of Columbia Jail.—Typhus fever, which has prevailed with varied virulence for a month past at the United States Jail for the District of Columbia, has assumed such a malignant and epidemic form, that, on recommendation of Dr. Buhamel, jail physician, the court has discharged about forty inmates confined for minor offences; and the Secretary of the Interior has put at the Doctor's disposal one of the hospitals at Judiciary Square, to which the sick are removed.

Assignments to Duty of United States Army Surgeons.—The following orders have been recently promulgated from the Adjutant General's Office:

Surgeon John E. Summers, United States Army, assigned to duty as Medical Director, Department of the Cumberland.

Brevet Colonel Ebenezer Swift, Surgeon United States Army, relieved from duty at Louisville, Ky., and assigned to duty as Post Surgeon at Jefferson Barracks, St. Louis, Mo.

Brevet Lieut.-Colonel D. L. Magruder, Surgeon United States Army, relieved from duty as Medical Director, Department of the Platte, and will proceed to St. Louis, Mo., and await there further orders.

Brevet Lieutenant-Colonel R. H. Alexander, Surgeon United States Army, relieved from duty in the Department of the Missouri, and will report in person to the Commanding General, Department of the Platte, for duty as Medical Director of that Department.

Report of the New York Society for the Relief of the Ruptured and Crippled.—According to the third annual report, recently issued, the number treated for the past three years has been 3,282, of whom 3,253 have been relieved. Of the above number 987 under 16 years of age, laboring under morbus coxarius, rachitis, paralysis, lateral and other spinal deformities, club-foot, etc., etc., have been restored to the free use of their limbs, and for their cure over 80 surgical operations have been performed. The society furnishes trusses, supports, laced stockings, bandages, and other surgical appliances. The cost thus far has been less than $5 per head. With a commendable enterprise, which it is hoped will be liberally seconded, they have purchased, for the sake of securing more ample accommodations, their present premises No. 97 Second Avenue, which before this was only suited for a house of reception and the treatment of out-door patients.

Original Communications.

THE TREATMENT OF CERTAIN FUNCTIONAL AND ORGANIC AFFECTIONS OF THE NERVOUS SYSTEM.

BEING REMARKS MADE BY INVITATION BEFORE THE AMERICAN MEDICAL ASSOCIATION AT THE LATE MEETING HELD IN BALTIMORE,

By PROF. C. E. BROWN-SEQUARD, M.D. F.R.S., etc.
OF NEW YORK.

I PROPOSE, gentlemen, to offer a few remarks which shall bear more particularly upon certain improvements which have been made within the last twenty or thirty years in the treatment of nervous affections. In introducing this subject I can only refer to the great influence which a proper knowledge of the reflex phenomena has exerted upon an accurate appreciation of the causes which are at work in producing both functional and organic affections. I will not have time to discuss the philosophy of reflex action in its relations to nervous phenomena, but will simply remark that most of the facts which I am about to present fully establish the importance of the knowledge that all morbid manifestations may be due to a reflex influence. I will only allude, in passing, to one or two facts in connexion with this part of my subject, which would be observable in the relation of cause and effect by the most casual observer. The fact that a wound of a superficial part of the body produces tetanus, is a well known circumstance, and in itself is a sufficient *à priori* evidence that the cause of that nervous affection may proceed from a reflex influence. Again, the fact that epilepsy is induced in some instances by the pressure of a bullet upon a branch or the trunk of a nerve, and is as quickly and effectually cured by the removal of the missile, is a very patent argument in favor of the theory. I do not think it necessary to multiply examples; but will make the statement that in almost all nervous affections, whether functional or organic, the cause is very often a reflex influence. For instance, a marked congestion of the spinal cord, or of the brain itself, can very frequently be traced to a peripheric irritation as its starting-point. Let a cold current of air be applied to a part of the body that may be warm, the nerves of that particular part are irritated thereby, the irritation is transmitted to the brain or spinal cord, and congestion is the result. A full knowledge of the frequent production of nervous affections by a peripheric irritation, gives us a very important indication for treatment, which must necessarily consist in the removal of the cause of irritation, whatever it may be. If we can trace a congestion to cold applied to any particular part of the body, we must take the necessary means to counteract the bad influence which it has exerted upon the nervous centres by remedies applied directly to the starting-point of the irritation. For instance, if the nervous symptoms can be traced to the immersion of the feet in cold water, we must direct our applications to these extremities; we must induce a counter-irritation of those parts. By this intelligent direction of our therapeutic means, we accomplish a great deal, and may even by the simplest remedies arrest what may seem to be, and if neglected may certainly become, a very serious disease.

After these few remarks, I come to another very frequent cause of nervous affections. This is also of very great importance to consider. Any alteration in the secretion of a gland, no matter how unimportant that organ may seem to be for the preservation of our health, may be the cause of a nervous complaint. I can give illustrations of this, were it not patent to the minds of every one that such is the case. In connexion with this point, I cannot urge upon you too strongly the necessity in every case of nervous affection of looking carefully after the condition of every organ of the body, and assuring yourselves, if possible, that no peripheric irritation exists. Such an irritation might be found to reside in an old cicatrix which has been healed twenty years, and in which not even pain is felt.

I pass now to consider a great many means of treatment which are of importance in nervous complaints.

Pressure on the Carotid for Congestion of the Brain.—I will first speak of pressure upon the carotid as a means which has been employed against headache, against congestion, and against inflammation of the brain. This treatment was employed in the view, that by stopping circulation in that blood-vessel, the amount of blood in the brain was diminished. But this is far from being the case. Whatever apparent good effect there may be from pressure in the region of the carotid, it has nothing to do in diminishing the supply of blood to the brain; but it is chiefly a pressure on the cervical sympathetic nerve which brings about the result; for that nerve being irritated by such pressure, causes a contraction of the blood-vessels of the brain.

Ligature of the Carotid.—The carotid has been tied for the cure of epilepsy; but this is a most irrational treatment, and I hope it will eventually be abandoned. It has been employed not only in epilepsy, but in diseases of the brain, which, in common with that affection, were supposed to depend on congestion of the brain. But in this case, as in the one in which simple pressure on the carotid is used, the congestion is diminished by some irritation of the sympathetic. If surgery should be bold enough to divide this nerve (which, perhaps, may be before long), a great advance might be made in the treatment of epilepsy. The loss of consciousness depends altogether, in the beginning of the attack, on the contraction of the blood-vessels of the cerebral lobes, producing in these parts of the brain a state of syncope. The loss of consciousness which occurs in the *petit mal*, might be avoided altogether by the extirpation of an inch or an inch and a half of the cervical sympathetic nerve. The teachings of physiology and pathology, and particularly the results of my experiments on animals rendered epileptic, conclusively show that there can be no chance for a loss of consciousness after this operation is performed.

Cauterization of the Urethra.—LALLEMAND, who has written an excellent work on seminal losses, and the nervous complaints due to this genital affection, has employed against it a plan of treatment which consists in cauterization of the urethra. There is a much better mode of treatment, I think, for these complaints than the severe and rather dangerous one of cauterization, which not rarely causes a stricture. The means which I have found most available are:—Pressure on the prostate, whereby the congestive state of that organ is diminished. The same thing will happen when ice or a very cold douche is applied to the perineum. I have also often obtained a considerable amelioration, and sometimes a cure, by a medicinal and hygienic plan of treatment, consisting in the use of atropine, the ergot of rye, large doses of the bromide of potassium, with tonics. Atropine and the bromide of potassium have a specific action on the prostate and the genital organs; and so great is that power with the bromide, that it will reduce the pain and erec-

tion in chordee, and diminish if not abolish sexual desire. But the dose of the bromide, to produce these effects, must be a large one; for instance, a drachm twice a day. There is no danger in using it in such quantities, and the only effect which may be troublesome is that the patient may get very sleepy.

Tracheotomy, etc.—Tracheotomy has been proposed by Marshall Hall against epilepsy. But the spasm of the glottis for which the operation is advised is only a symptom—a result, and not the cause of epilepsy. It is, then, only of service as a temporary amelioration. I need not say here that the theory of Marshall Hall in reference to epilepsy is, in my opinion, entirely wrong. However, it may be well to be prepared to operate if an emergency should arise. Dr. Lalor, of Dublin, has ascertained that food is sometimes thrown from the stomach into the larynx and trachea in fits of epilepsy, causing death by asphyxia. Tracheotomy would, of course, be useful in such cases.

Extirpation of the Clitoris.—Extirpation of the clitoris for nervous affections is an operation which cannot be approved of on rational grounds. Mr. Baker Brown has been in the habit of treating several kinds of nervous affections by this method; but I cannot agree with him in thinking that it is a proper treatment, when there is not a manifest connexion between a morbid state of that organ and the nervous disorders. You know that onanism is a very frequent cause of nervous affections in women as well as men. There are cases on record, and others not published, in which that operation has not been attended either with a good effect upon the nervous trouble or upon the loathsome habit. I know several cases of this kind. That which I have found more serviceable when moral advice has failed, is the production of a sore close upon one of the parts handled, so that every attempt at friction will cause a pain compelling the patient to abstain from it. The sore must be kept open until the general health is sufficiently restored to allow the moral influences to be brought to bear upon the patient with good effect.

Extirpation of the Testicle.—As regards ablation of the testicles, I cannot speak in words of disapproval strong enough. It seems to be not only a very irrational but a barbarous procedure, and it was certainly so in most of the cases in which this operation was performed against epilepsy.

Section of Nerves.—One of the modes of treatment which have been found of great importance in the treatment of epilepsy, tetanus, and other complaints which are due to an irritation of nerves by a wound, a burn, etc., consists in the section of irritated nerves, at some distance above the wound or burn—*i.e.* between the point of irritation and the nervous centre.

Actual Cautery.—In regard to the use of actual cautery in nervous affections, functional and organic, I am sorry to say that this method of treatment, which is perhaps too much employed in France, is too much neglected in England and in this country. I have often applied the white-hot iron to the head of patients in the coma of apoplexy, of cerebritis, of uræmia, or of epilepsy, with almost always the good effect of freer breathing. Many patients have been aroused from coma by that means alone, and not a few have recovered, whose recovery was at least partly due to that mode of treatment. The application of the hot iron to the nape of the neck has been often found of signal service, in cases of any functional nervous complaint in which it may be found necessary to change the nutrition at the base of the brain. I hardly need say that the actual cautery is one of the best, if not the best means of treatment of neuralgia and rheumatic pains.

Application of Ice.—Opposite to this, but acting in the same way, is the local application of ice to the spine and various parts of the body. This plan of treatment has also been too much neglected. It may be extremely beneficial in a number of affections. Dr. Chapman, of London, has published some cases in which the beneficial results of the application of ice to the spine in certain nervous complaints have been very apparent. These cases are not so complete as one would wish to have them; still I have no doubt that the principle upon which he founds his plan of treatment is a tenable one. I have no doubt also, that ice to the spine in certain kinds of epilepsy, particularly in those cases where there is evidence of a spinal irritation, will be of real benefit.

Circular Blisters and Ligatures.—I come now to another method of treatment, which, according to the results of my own practice, is of considerable importance. When I began to have charge of an immense number of paralytics and epileptics at the National Hospital in London, I found that, in most of the cases in which ligatures are useful against epilepsy, they act in quite a different way than that which is generally admitted. I ascertained that it is the irritation of the nerves of the skin, and not a pretended obstacle to the passage of the so-called aura, which, in cases of an aura of centric origin, produces the good effects of preventing a fit or diminishing its intensity. I found that pinching, pricking, or a blow, acted almost as well as a ligature; and these facts, and others that I have not time to mention, led me to admit that an irritation of the nerves of the skin in limbs can produce a very favorable change in the state of the base of the brain, and also in the spinal cord. This view made me adopt a plan of treatment which has proved useful, not only in epilepsy, but in hysteria, in chorea, in trembling palsy, and in cases of congestion or inflammation of the base of the brain, or in cerebral meningitis. This plan consists in the application of blisters, one inch in width, all round a limb attacked with either paralysis, trembling, jerks, or pain, due to a congestion or inflammation of the nervous centres or their meninges. These circular blisters produce an irritation of cutaneous nerves through which a favorable change takes place in the circulation or nutrition of the nervous centres. This mode of treatment is generally much more useful than the application of counter-irritation to the head, the nape of the neck, or the spine.

Errhines.—There is another means of treatment which I cannot pass by without a notice, and that is the use of errhines. I am convinced that these are not employed as often as they ought to be. These medicaments are of special utility in cases of nervous affections (epilepsy, headache, congestion of the brain), attended with sensations of fulness, heaviness, tightness, etc., in the frontal sinuses.

Within the last few years subcutaneous injections of morphine, quinine, etc., have been very much employed. I will only say that this plan of treatment is a most invaluable one, and that it is absolutely free from any great danger if carefully employed. There is frequently, however, *some* danger, and medical men should be prepared for it. I do not mean to say that life is compromised by the treatment, but that phenomena will sometimes occur which may seriously compromise the reputation of the practitioner. I usually employ morphia, together with opium, in cases in which it seems useful to inject narcotics. The doses are from one-third to one-half of a grain of the sulphate of morphine, with from the one-sixtieth to the one-fortieth of a grain of the sulphate of atropine. I have for a good many years injected these narcotic salts together. Not that I believe that they are antagonistical in the way

that many suppose. I deny that a dose of morphine, able to destroy life, can be neutralized by any quantity of atropine. I have an opinion contrary to authorities in this respect. I have given a dose, by injection, to a dog sufficient to kill him in a certain time, and have immediately afterwards injected the prescribed amount of atropine to counteract it. I have seen most of the symptoms caused by the first alkaloid diminish in consequence of the action of the last injection, but death took place nearly at the same time as if I had not injected the atropine. My experiments prove that these narcotic remedies and poisons are not antagonistic as regards their deleterious, toxic, or poisonous effects, however much they are antagonistic as regards some of their effects on the nervous centres, the eyes, etc. They should be employed together, according to my notion, on account of their real antagonism, and also on account of the addition of the good effects of each of them to those of the other, against pain particularly.

I now pass to consider other remedies. The bromide of potassium is an invaluable remedy. The dose for epilepsy should be a scruple three times a day. The best time to give it is when the stomach is empty, so as to allow of its rapid absorption. But I have found that, in certain forms of epilepsy, the use of bromide of potassium alone is not so good as when it is combined with other remedies. The best remedies to be used, together with this salt, are the iodide of potassium and the bromide of ammonium. The iodide of potassium will not do much alone against epilepsy, unless it be due to syphilis, and then the dose must be extremely large; but if the bromide of potassium be added to a small dose of the iodide, the good effect of these two salts employed together will be increased, especially in cases of epilepsy allied with, or due to, a congestion in the base of the brain, manifesting itself either by a slight hemiplegia, or by other symptoms. These two remedies are very different in their action, although there are many physicians who believe that they are almost identical. Bromide of potassium produces anæsthesia of the throat and larynx, dilatation of the pupil, deafness, anæsthesia of the urethra, and a diminution of the sexual power, etc.; but none of these symptoms are produced by the iodide of potassium. On the other hand, the iodide of potassium will sometimes cure syphilis, while the bromide of potassium has no power whatever over that disease.

I said bromide of ammonium should be sometimes employed together with the bromide of potassium. There are cases of epilepsy in which the combined use of these remedies is of great value. In cases where there is suspicion of the existence of congestion of the base of the brain, and still more of a congestion of the spinal cord, or its meninges, the bromide of ammonium will give a decidedly greater effectiveness to the bromide of potassium.

The bromide of ammonium is a very valuable remedy in hooping-cough, as first shown by Dr. Gibb and Dr. Harley, of London. As I have named that disease, I may here mention that there are other modes of treatment of more value. One of these modes is by the use of atropine. But if you employ it you have to be by your patient, as it is necessary to give it in doses large enough to produce delirium, and to keep up that condition for three days, except at night. In the evening you may give morphine, or what is better, codeine, or narceine. This will procure a quiet night's rest. You must watch your patient to see that the delirium does not go further than it ought to. If you can get the consent of the parents to allow the use of this remedy, you may be able to cure your patient at the end of three days, as I did in a bad case of hooping-cough in my own child. I need not say that the bronchitis, allied with the hoop, will persist some time after the cessation of this nervous phenomenon. It will, however, be very hard work to get the consent of the parents if you tell them beforehand how the medicine will act; but some may give you a chance.

I will now say a few words on another remedy, which is too little employed; I mean the chloride of barium. I have given it in one case of trembling palsy with a very gratifying result. This is the only case of that affection in which I have obtained a complete cure. In some of the other cases in which I have tried that remedy, there was a marked amelioration of the symptoms. The dose of this remedy must be a large one—from half a grain to one grain three times a day. This is a dose which, according to writers on toxicology, might be sufficient to kill outright. I can only say that these writers are quite wrong. This remedy, in very large doses, has lately been employed with success in several cases of tetanus.

Codeine and narceine are remedies which I have used a great deal; more especially is this the case with the former. Codeine is a most valuable remedy to give a quiet night's rest. In this connexion I must refer again to the bromide of potassium as an invaluable remedy to produce sleep in persons who are wakeful on account of severe anxiety, grief, or any other moral cause. The dose too of this medicine must be pretty large. About four or five P.M. as much as thirty or forty grains, and another dose equally as large by eight or nine in the same evening.

I will only say a few words on two or three other remedies. In nervous affections, due to congestion of the kidneys, or of the ovaries, I have found the use of gallic acid in four or five grain doses, six times a day, of singular efficacy. It is much better to give it in frequently repeated doses than otherwise, as it is less apt to disturb the stomach.

The nitrate of silver has been considered a very excellent remedy in the treatment of that newly-studied affection, the locomotor ataxy. The great expectations that were entertained of its efficacy have not, however, been realized, and it has been found that instead of curing the majority of the cases, it has sometimes only succeeded in blackening the skin. It is, however, when used properly, of some value; but it should not be used longer than a month at a time, for by allowing an intermission, say of a month, it has pretty much as good an effect as when taken without interruption, and does not alter the color of the skin.

In conclusion, gentlemen, allow me to make this single remark, that in the treatment of nervous affections, you cannot search too diligently for their cause in all the organs of the body; and that far from the study being an exclusive and especial one, it is necessary, before undertaking to practise with chances of success in this department of the medical art, to have a knowledge of the diseases of every organ. The best specialist for nervous affections is he who joins to a specially extensive knowledge of all the forms and varieties of nervous complaints, a thorough acquaintance with all the general and special diseases and disorders of every part of the human frame in themselves, and particularly in their relations with the nervous system.

The Pulse at Different Altitudes.—In ascending into the air, the heart-beats increase 5 for the first 3,000 feet, 7 more for the next 1,500 feet, 8 for the next 1,500, and 5 for each 1,500 feet of ascent after that. This is an average increase of one beat for each 100 yards of ascent.

LARYNGOSCOPY.

BY J. SOLIS COHEN, M.D.,

OF PHILADELPHIA.

Any method of exploring diseased structure which shall remove from the mind uncertainty as to its character, is of immense value in the practice of medicine. Hence, the universally recognised importance of *physical diagnosis.*

When percussion and auscultation permitted the diseased heart and lungs to murmur their own tale of suffering to the listening ear, the correct application of therapeutics became at once more definite; and, since Czermak has instructed the profession how to obtain an insight into the condition of the larynx and trachea, and parts adjacent, laryngoscopy displays to our eyes in their true colors, the exact nature of many obscure maladies heretofore classed among internal diseases, but which are now recognised *during life* in the performance of various vital functions, and rendered amenable to treatment as accurate and precise as the operations of the surgeon upon external structures.

Laryngoscopy (*inspection of the larynx*) is effected through the medium of the laryngeal mirror, which, as all valuable scientific instruments should be, is exceedingly simple in construction. A small looking-glass fastened to a slender handle is passed to the pharynx, and held in such position that light falling upon it is reflected upon parts below, so that their image becomes mirrored on its surface. *This simple laryngeal mirror is the only essential instrument absolutely necessary for the performance of laryngoscopy.*

When the light of the sun is insufficient to illumine the mirror satisfactorily, artificial light must be resorted to; and may be employed directly, or concentrated by means of a lens or series of lenses placed in front of the flame, further aided and controlled, when desired, by the employment of a reflector.

The source of the light is not important. A steady, well directed light is far preferable to illumination more intense or brilliant, but unsteady or ill-directed. An ordinary reading-lamp, such as the coal-oil or petroleum lamp in common use in this country, will answer every purpose for ordinary examination; while those who prefer it, and have the facility, can employ the familiar gas-burner. Ordinary illuminating gas burns more steadily and brightly through an argand burner; and the light given by coal-oil can be increased by mixture with burning fluid, or by dissolving camphor in it (after the manner of the endoscopists), in the proportion of 10 or 12 grains to the ounce.

The writer prefers a petroleum light of the intensity of an argand gas-burner. The light is whiter and steadier, and softer than that of gas, while pleasanter to work by and fully as brilliant. There is no flickering, as in the escape of burning gas from a jet, no matter how controlled or protected; nor is there any danger of inequality of pressure at the gas-works to cause disappointment in the degree of illumination and its character.

Artificial light being more thoroughly under control, whatever may be the hour of the day, the state of the weather, or the location of the apartment in which the examination is to be conducted; and there being from natural causes some variation in the color of objects as viewed by natural or artificial light, it will be found preferable for those who desire to practise laryngoscopy extensively, to accustom themselves to the exclusive use of artificial light; for this will prevent any inaccuracy of judgment as to the true progress of a case examined indifferently by either source of illumination.

The intensity of the artificial light can be greatly increased by placing in front of it an ordinary plano-convex (bull's-eye) lens, from two and a half to three inches in diameter, the plane surface towards the flame at the proper focal distance of the lens; or a tubular or other shaped lantern to surround the light, with arrangements of achromatic lenses, may be constructed by those who desire to provide themselves with some of the refinements of the art. This is a fruitful field for display of taste, and almost every observer (Voltolini, Lewin, Tobold, et al. ad infinit.) who has written on this subject has devised an arrangement of lamp or lantern of his own, which gives a better and brighter light than any form or combination previously contrived by anybody else. The ordinary glass globe (Störk) used by the shoemaker, six inches in diameter, filled with water and placed before the light, will furnish a brilliant illumination at a distance of about twenty inches. This arrangement is much employed by Störk, Wagner, and others, for direct illumination.

Calcium lights, magnesian lights, Drummond (properly Hare) lights (Türck), photo-oxygen lights, a stream of oxygen passing through a photogen lamp (Voltolini), electric lights, and every other known description of lights, have been variously recommended in some one or other portion of the continent of Europe; but a good gas or lamp-light, such as one is accustomed to read or write by at night, is all that is required, and, concentrated by a plano-convex lens, will be found amply sufficient for all practical purposes; and where economy is an object, the glass globe filled with water, and supported on the ring of an ordinary retort-stand, affords an admirable substitute.

In using direct artificial light in this way, the rays pass to the fauces from the side, in order to secure freedom of movement to the operator, unless the light is placed between the operator and his patient, which is always inconvenient, and cannot be well done when the globe is used.

When the rays thus pass into the mouth from the side, from the conformation of the cheeks, some portions of the structures to be examined will at times be in shadow, for the whole of the larynx and its contents cannot well be illuminated at one time; and it may therefore become necessary frequently to alter the position of the light, the management of which, before a satisfactory examination will have been made, will become extremely troublesome. As it is often requisite to be enabled to shift the direction of the light promptly and readily, it will be found more convenient to employ a reflector which shall receive the rays from the lamp, and reflect them from before backwards to illumine the laryngeal mirror in position. A concave silvered ground-glass reflector, of about three to three and a half inches in diameter, and with a focal distance of from nine to fourteen inches, will be found the most convenient and perfect instrument for general use.

Borrowing the idea of the reflector from the ophthalmoscopic reflector of Rüette, many observers insist on the necessity of perforating its centre, or at least removing the silver coating, and looking through this exposed portion. If considered desirable to limit vision in this manner, the distinct perforation is preferable, as sight must certainly be clearer without any intercepting refracting medium. The conditions necessary for an examination of the fundus of the eye, and those requisite to perceive the image depicted on the laryngeal mirror, are entirely different; there are no series of refracting lenses intercepting a distinct view of the laryngeal image, which can be discerned with perfect distinctness even when the eye is at some distance from the margin of the reflector. Further, in practising auto-

laryngoscopy (inspection of one's own larynx) the use of the perforation of the reflector is wholly impracticable, as will be explained in treating of auto-laryngoscopy; and although the image, again reflected before being seen by the observer, is sufficiently distinct for the expert operator to demonstrate to others the whole contents of his own larynx, he will insist on the necessity of confining vision to one eye, limiting its range by a small opening, in examining the more perfect image of the larynx of a patient. Still, as the perforation does not injure the reflector for binocular vision at its margin, and an occasion may arise for putting the best eye forward for some rapid squint, it may be well enough for those who desire but a single reflector to provide themselves with one that is perforated.

When the direct rays of the sun are too strong to be well borne by the patient, or when it is impracticable to secure a comfortable position, a reflector may be employed with natural light also. In this case the surface of the reflector may be plane, and an ordinary toilet mirror will answer the purpose; but if the diffused light of a room is used, a concave reflector is necessary to converge the rays. Of course, it will be understood that in employing natural light, the position of the reflecting mirror, as well as the position of the patient, will have to be changed frequently as the day advances, unless an expensive heliostat is employed.

Semeleder "found it convenient to throw a cone of light into the room by means of a concave mirror attached to the window, upon which the sun shone; then to seat himself and the patient within this cone; to collect anew the diverging rays by means of the illuminating apparatus, and then to apply them to the examination. Thus we obtain a soft light which is not blinding, and with which one might work by the hour together."

Dr. Eben Watson, of Glasgow, found "that a range of houses opposite to his consulting-room window acts the part of a reflector, and saves him the trouble of using a metallic one."

The reflector may be placed before one eye (Czermak, Semeleder, et al.); in front of the nose and mouth (Von Bruns); or on the forehead (Moura, Johnson, Mason, etc.). It may be attached to a stem to be held in the hand (Babbington, Czermak, Türck, etc.); to a handle to be held between the teeth (Czermak); to a frontal band (Kramer); to a spectacle frame (Semeleder); to a horizontal arm coming from the illuminating apparatus (Tobold); to a tripod at the side of the patient (Türck); to a vice for fastening on the edge of a table (Fauvel, et al.); or to a portable telescopic stand. In every case, however supported, it should be movably attached to its support by suitable swings and hinges; or, what is preferable, by a ball and socket joint, so as to secure freedom of motion in any desired direction. When placed in front of either eye, which must then be applied to a perforation, the observer looks in the exact direction of the axis of the rays—theoretically, certainly, the most favorable position for accurate vision; but the degree of divergence between visual and illuminating rays is so slight when looking by the side of the mirror, or above or below its margin, that in the actual practice of laryngoscopy it is not really a matter of much importance. The desired object is to secure a distinct view of the image depicted on the mirror held in the fauces, and so that this object is attained, every one will prefer that arrangement of reflector to which he first takes fancy, or to which he becomes earliest accustomed.

There is certainly some advantage to be gained in attaching the reflector to the observer's head; the direction of the light can be altered readily, and it soon becomes comparatively easy to follow with the head the movements of the patient, so as to keep the light reflected on the fauces; but the writer prefers to teach his patients to keep their heads still; and after they have learned this first lesson, examination and the application of instruments are effected much more easily and satisfactorily than when the doctor has to keep bobbing his head about after that of the patient; to say nothing of the lack of dignity in thus attempting to follow the movements of a fractious child, or a mischievous one, who will move his head purposely; besides, after once permitting a patient to exercise a considerable degree of latitude in moving his head, it will be found much more difficult to teach him to keep that organ still, than when this necessity had been quietly impressed upon him from the very first interview.

Nor is it necessary to confine the patient's head as in a vice, though this has been done; but if he is informed that it is important that he should keep his head still during the examination, so that the light can remain properly directed, it is rarely that a little patience will not accomplish the object.

If attached to the head of the operator, the reflector will be much more conveniently placed in front of the forehead than before one eye; as it is less difficult of adjustment, and does not impede the use of either hand; while it certainly presents a more elegant appearance than when stuck in front of the nose. Semeleder's spectacles are preferred by a great many operators, but considerable practice is necessary to become thoroughly at home with them. Semeleder's reflector is perforated, but if it is to be worn in front of the forehead or nose, there will be no necessity for the perforation. It is certainly easier to manipulate the laryngeal mirror or instruments with the eye removed from the perforation of the reflector whether attached to the head or on a stand; and the tyro is apt to miscalculate his distances when first attempting to introduce an instrument with one eye confined to a small opening; even if monocular vision is as satisfactory as the natural binocular vision. In the examination of patients confined to bed, whom it may not be desirable to raise from the recumbent position, the reflector attached to the forehead will be found very convenient, especially when artificial light has to be held in one hand; and it is also exceedingly useful to lighten up the parts for the examination of the mouth and contents in ordinary practice, as has often been done less commodiously with a hand mirror, leaving the hands free for other purposes, and enabling satisfactory examination to be made promptly without too close proximity to the foul breath so frequently accompanying malignant and other diseases.

Czermak's method of holding between the teeth a plate to which the reflector is attached by a stem, is objectionable, inasmuch as the effort of keeping it in position is annoying, tiresome, and awkward; besides rendering it difficult for the examiner to give directions to his patient, which are often highly necessary to obtain certain muscular movements of the larynx and other parts, to bring into view structures which would not be seen otherwise.

The form of the laryngeal mirror is not a matter of much importance. Circular mirrors appear to be more readily borne by a greater number of patients than those of other shapes; but the square mirror, with the shank attached to one corner, is probably used as frequently; and oval mirrors are of advantage in cases where the tonsils are swollen, or where the fauces are too irritable to permit the introduction of a circular mirror. Many other forms of mirror have been employed. Thus, there are elliptical, rectangular, pyriform, lozenge-shaped, dome-shaped, heart-shaped, etc., etc.; but for constant use the circular mirror will be found able to meet all indications presenting.

The diameter of the mirror may vary from half an inch to an inch and a quarter or more; the larger the mirror that can be employed in any particular case, for obvious reasons, the better. The mirrors most in use are made of glass, coated with quicksilver or amalgam; but when the glass is ground and silvered, the reflecting surface is very fine. The mirror should be perfectly white, and then objects will appear in their natural colors; quicksilvered mirrors have usually a bluish ground, and many have a yellowish tinge, which will of course affect the correctness of the image. Only the finest white glass should be employed in their construction. Mirrors were first made of metal, and highly polished steel forms the best metallic mirror; though they may be made of silver, speculum metal, or copper plated. A glass mirror is much clearer than a steel mirror, and has a greater reflecting power; it can be made to have a clear white ground, while the ground of the steel mirror is of a dark bluish or violet color; but in steel mirrors there is no refracting medium above the reflecting surface, of which, too, there is no space lost in the setting; still as they rust easily, soon become scratched, altered by heat, spoiled by the spattering of secretions from the mouth or throat, or from particles of corroding solutions which may be used in medication, they are difficult to keep in good order; and are therefore most applicable to special cases when but a small mirror can be employed, and it is desirable to avoid the loss of reflecting surface caused even by a narrow setting.

The most convenient angle at which the mirror can be attached to the shank, which should be of pretty stiff wire, will be found to be about 125°; but the exact angle its reflecting surface, when introduced, should bear to the laryngeal aperture will depend much upon the natural conformation of the parts (for they differ in individuals as well as outward structures), as also upon the degree of flexion of the head, the positions of the reflector, and the eye of the observer, etc.

This will all become regulated intuitively as practical acquaintance with manipulation is acquired.

Original Lectures.

ON CHOLERA.

By A. CLARK, M.D.

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

Lecture VII.

Fatality of Cholera.—Influence of Age and Sex on the Liability to the Disease.—The Treatment of Cholera by Opium, Stimulants, Blood-Letting, and Calomel.

I have but a few considerations more to present to you relating to the general history of cholera.

The fatality of the disease in relation to the number attacked, is a problem not easily solved. During an epidemic, hospitals are numerous; officers in each desire to excel those of the others in the number of their cures. Some have a favorite plan of treatment, which they sometimes allow themselves to magnify at the expense of truth. Then there is a lack of uniformity in the character, or rather condition, of the reported cases. Some physicians report everything that is marked by diarrhœa in a cholera season. Others enter as cholera only the cases in which the diarrhœa has become watery, and is attended by vomiting and cramps. But from the best reports we can find, I think we may say about one-half of those admitted into hospitals die. Yet in Paris, in 1832, in the early period of the epidemic, Drs. Pinnock and Gerhard inform us that of the first ninety-seven cases received into the Hotel Dieu, ninety-six died. They state that these were not in the practice of any single physician, but were distributed through the hospital, and treated by some of the best physicians of that city. They further add that this extreme mortality was nearly or quite equalled in the principal hospitals of Paris at that time. At other times we hear reports of small numbers treated, even in the state of collapse, all recovering. But it cannot be doubted that a very large majority of those who pass into this stage die, whatever may be the plan of treatment adopted.

It appears from statistical returns that the cholera of 1832 attacked in France, exclusive of the military, 230,000 persons; and of these 95,000 died. This is a proportion of one in 2.42. In Quebec in 1832 the reported cases were 5,783; deaths, 2,218; being one in 2.50 of those attacked. In Montreal the deaths were 4,420, or one in 2.50 attacked. In New York they were reported one in two. In Philadelphia 2,314 and 935, or one in 2.50. In this connexion it is important to make a distinction between the cholera cases treated in public institutions and those treated in private houses. The Philadelphia physicians report that of eleven hundred and seventy-five cases in private practice, two hundred and seventy died, and no more; making a mortality of one in four and three-sixteenths. In general there is no doubt but the mortality in private practice is very much less than in hospitals. The proportionate mortality is almost always greater in the early period of an epidemic, and for any one locality attacked this greater fatality continues eighteen to twenty days, when the type of the disease usually becomes milder. At each new locality in a city where the disease appears, the same thing is noticed; so that the stage of the epidemic should be stated in comparing the fatality in different returns.

Dr. Baly has published a table, showing the danger to life during epidemics, from which I give the following extracts:

CHOLERA,

DEATHS FROM, IN TEN THOUSAND LIVING IN VARIOUS CITIES.

		Through the whole epidemic.	In most fatal month.
London,	1831–2	37	9
"	1848–9	61	22
Liverpool,	1848–9	163	61
Hull,	1849	236	167
Sunderland,	1848–9	55	18
Belfast,	1848–9	154	42
Dublin,	1849	69	20
Glasgow,	1848–9	35	19
Paisley,	1848–9	30	21
Paris,	1832	235	162
"	1849	182	82
Berlin,	1831	52	23
"	1832	16	9
"	1837	80	41
"	1848	34	19
Cronstadt,	1831	546	509
Stockholm,	1834	452	421
St. Louis.	1849	535	212
New York,	1849	112	58
Philadelphia,	1849	29	20

The rate of mortality is here shown to be lower in

London than in any large city in the list, except Philadelphia. London boasts of lower death rates from general causes than any European town, and has taken great pains to relieve itself of the causes of all preventable diseases. The ratio of deaths by cholera to the number of persons living in London in 1831–2, was about 1 in 270; for the epidemic of 1848–9, 1 in 164; the latter continuing fourteen months. The highest death rates given in this table were noted at Cronstadt; viz. 1 in 18 nearly, and all in a little more than one month. The next was at St. Louis, during about eight months of 1849, 1 in 18½; while during six months of 1849 in this city there was 1 death to 89 living; in 1832, 1 to 62; and in 1854, 1 to 240. In Philadelphia during four months of 1849, there was only 1 to 345. The death rate from all causes, exclusive of cholera, in New York, varies from 1 in 25 to 1 in 40. The chances of death by cholera in New York have never been equal to the risk from other diseases in any year. In 1854 it was only about one-eighth the general risk; in 1849 about one-third; and in 1832 only a little over one-half. In other words, in the worst cholera that has yet visited this city, any resident was in much greater danger of dying from ordinary causes during the year than of cholera during the epidemic; and in the last visitation the general risk was nearly eight times greater than the special. This mode of viewing the subject may well give confidence to timid and anxious persons whose duties confine them in town during an epidemic. Men in health do not contemplate with alarm the chances of their own death within a coming twelvemonth; why should they not meet with equal calmness the smaller risks of an epidemic cholera? It does indeed become alarming when, as in Sandusky City, it sweeps away one-third of the population; but Sandusky suffered the extreme of mortality. The disease has not visited a large European or American city with any approach to such malignancy. The death of one in eighteen at Cronstadt was probably owing to removable causes; but a nearly equal mortality at St. Louis, being greatly among emigrants, was not wholly within the remedial reach of that city alone. The lesson which these considerations teach is to prepare for a threatening epidemic by cleansing in-doors and out of doors; removing every possible cause of insalubrity; putting the poor into the best condition to resist the attack; excluding, as far as possible, the approaching disease, and await with calmness the issue.

The estimates which I have here presented to you, do not quite cover the whole ground. Diarrhœa, and dysentery, and cholera-infantum are generally more fatal in cholera seasons than in others, while cholera-morbus is probably charged with a part of the mortality produced by the epidemic. Thus in 1832 the mortality from cholera-infantum exceeded the average of the two preceding years by 164 deaths; that from cholera-morbus by 83; while the deaths from diarrhœa and dysentery fell short of a similar average, respectively 8 and 6. Thus we have 247 deaths to add to the 3,513 caused by cholera. This will increase in a slight degree the epidemic risks of that year. In 1849, by comparison with the average of the two preceding years, the deaths by cholera-infantum were increased 328; by cholera-morbus, 179; by diarrhœa, 278; and by dysentery, 558; in all, 1,361 deaths to be ascribed to the epidemic tendencies, and to be added to the 5,071 by cholera; but with this addition the risk of death by choleraic influences that year was less than half the risk from other causes. The account for 1854 stands thus: Deaths exceeding the average of the two preceding years by cholera-infantum, 607; by cholera-morbus, 214; by diarrhœa, 580; by dysentery, 913; in all, 1,492. Add this to the cholera mortality, 2,509, and it will make 4,001 deaths in a population of 600,000, or 1 in about 150; from one-fourth to one-fifth the usual annual risk. These conclusions will be again somewhat modified by making an allowance for those who leave the city during a pestilence. But almost all New Yorkers who are able to do so leave the city every summer, so that the difference between a cholera summer and a summer of usual healthfulness is not, in this respect, very great. There is a more striking difference in the absence of non-residents, who in healthy seasons fill the hotels. But data cannot be obtained for any accurate estimates on either of these points, and I have thought it better to rest the calculations on the actual or estimated population of the city at the time of the epidemic invasions.

As to the influence of age on the liability to cholera, a word. It has been stated that the extremes of life are exempted. The error of this statement is patent to every physician who has seen much of the disease. The truth is, that both children and aged persons, in proportion to the number living, are more likely to die of cholera than the middle-aged. If you refer to the *Registrar-General's Report on Cholera in England*, 1848–49, p. 41, you may discover that the disease carried off 14,718 persons under 15 years of age; 30,628 between the ages of 15 and 60 years; and 7,901 who were 60 years old and upwards. Two of these were men aged 95 years and upwards. The Registrar is disposed to add the deaths from *diarrhœa* to those caused by cholera, in the belief that they are to be referred to the same cause. Of these there were 12,852 among children, or persons under 15 years of age; 2,633 between the ages of 15 and 60; and 3,398 of those who were 60 years old, or upwards. The fatality of diarrhœa, in cholera seasons, is made very striking by these figures. Combining these diseases, he rates the mortality of children under 5 years of age—boys at 88, and girls at 78, in 10,000 living. The proportionate mortality then declines rapidly between 5 and 10, but begins to rise again between 25 and 35, when it is about 31; between 35 and 45, it is 41 and 44 for males and females respectively; and above 45, for successive periods of ten years, it is 54, 70, 92, 114, 135, in 10,000 living of corresponding ages. Persons aged 85 to 95 living in England in 1849 were greatly more in danger from cholera and choleraic diarrhœa than persons of any other age, except, perhaps, the few who had passed this decennary; and we have to descend in the scale to about 70 years of age before we find the liability reduced to the level of infancy.

The disease falls with about equal severity upon the two sexes. In England during the epidemic of 1849 the deaths from cholera among males were 26,108; among females 27,182; from diarrhœa 9,637 males, and 9,250 females. So that from the two affections together 687 more females died than males. This does not imply greater liability to the disease on the part of females, for in countries not recruited by immigration, that portion of the population is greater than the males. In England, by the census of 1851, in a total of nearly 18,000,000, the number of females exceeded that of the males by 397,592. Indeed the balance is slightly against the males, for the report shows 1 death among 331 males, and 1 among 333 females. Notwithstanding this general equality, in different places, and in different months, the proportions varied considerably. It varied also at different ages. Thus 7,673 boys died of cholera under the age of 15 years, and 7,045 girls; or, including diarrhœa, the mortality was as 88 to 78. But from 25 to 45 years of age the mortality was greater among the females; between 35 and 45 it was as 44 to 41.

The only other statement I wish to make to you in

this connexion is that cholera does not protect against itself. It is true of most contagious diseases, that having once gone through them, the person is in a great degree protected against another attack. It does not seem to be true of cholera that a second or even a third attack may not follow the first. This fact has been made prominent by some observations of Mr. Barth in the cholera that has lat ly prevailed in Paris; and it has been noticed by a considerable number of observers.

We now come to considerations for which you have all been waiting with anxiety, if not with impatience. It is in the treatment and prevention of disease that our profession demands and receives the homage of the public. In our studies, however profound, however exhausting, so long as they are confined to the nature of diseased action, we are hidden from view; we awaken no outside sympathies; we strike hands with no common interests; the period of benefaction on the one hand, and of interest, or perhaps gratitude, on the other, has not been reached. We are not of the public, and have no hold on the public heart. The tree must grow, must even mature its fruit before it attracts the public eye, before it can supply the public want. It is by the qualities of this fruit that the culture is to be judged. The student naturally feels that if he has not acquired the art of curing, his science is of little value. This, too, is the judgment of the public, both forgetting that facts once demonstrated and recorded are something rescued from primeval chaos, and when incorporated with facts yet to be discovered may become the basis of the highest art. Yet I cannot say that I approach this topic with cheerfulness, but I am not humbled because we cannot cure cholera. I do not recognise any *opprobrium medicorum*. When I remember that within three quarters of a century, by the direct and indirect influence of medical men, human life has been prolonged an average of ten years, I am proud of my profession. I am as willing to contemplate what it has done and can do, as what it has not done—perhaps I should say what it cannot do. It has not achieved impossibilities; but if it has not in all things conquered success, it has done what an ancient general regarded as more meritorious, it has deserved success. It has at least expelled the word *opprobrium* from its vocabulary. Death is a law of life. The death of the individual is a condition necessary in the multiplication of the race. Death is inexorable, perhaps because the experiences of life and after-life are bequeathed to the greatest number. There are diseases over which the profession has gained little control, and there probably will be till time ends. I do not, however, believe that cholera is for ever to defy remedial efforts, notwithstanding the little that has yet been accomplished. They are chronic diseases mainly which have received the epithet incurable.

My aim in leading you to the consideration of the treatment of cholera is to tell you what has been done uselessly in former epidemics, that you may not lose time and human lives by following such theoretical suggestions as have been found to be fallacious guides; and to glean from the voluminous and conflicting testimony, often questionable in its correctness, through the bias of preconceived opinions, oft n untrue through perversions of facts to sustain theories, or to gratify personal vanity in making better returns than a rival is expected to make; to glean out of all this confusion what little there is that can diminish suffering, and improve, though it be only in a limited degree, the chances of recovery.

The first thought that presents itself to us in this connexion is the fact that internal medication can produce but little influence in the later stages of the disease. The extreme congestion of the vessels of the stomach and intestines, the viscid condition of the blood, the impeded circulation in the capillaries, will render the absorption of medicinal agents exceedingly slow, and in many instances impossible. Notwithstanding Majendie discovered the odor of camphor and of other odorous substances in the breath of cholera patients after they had been administered by injection, experiments by Duchaussoy seem to show that the most potent medicines may be given in doses ordinarily dangerous and produce no material effects. Indeed the whole history of the treatment of this disease leads us to suppose medicines incapable of producing their usual effects. Extract of belladonna has been given in six, eight, and twenty-two grain doses, and no effects have been observed from it. Heroic medication but causes the accumulation of drugs in the intestinal canal, and there they are left to operate upon the system if reaction occurs, or they are swept away by the abundant discharges. This is one great embarrassment in the treatment of the disease in its later stage. Keeping this fact in view, we may do well to look over some of the plans of treatment that have been adopted.

I call your attention first to what may be denominated the opium treatment. Opium has frequently been given in very large doses, and it has always, I believe, failed to cure. By this I mean that persons treated with this drug, though some of them may have recovered, do not present a favorable average of recoveries; and it is the almost universal opinion of those who have had most experience, that except in the initiatory stage, during the diarrhœa, opium does harm rather than good. I was called, during one of the later invasions of the disease, to see a distinguished gentleman in this city who had gone into the country, and was there attacked by cholera. The local physicians had conceived that they might control the discharges by opium, and had given it freely. He had passed through the collapse and had come into the stage of reaction, but was then fully narcotized, and he died apparently from the combined effects of the opium and urea in the blood. This fact you have already become familiar with, that opium may not be administered with great freedom where uræmia exists. Opium is doubtless serviceable against the premonitory or initiatory diarrhœa. I believe there is as much uniformity in the practice of the profession regarding its use then, as there is in discarding it afterwards. In the administration of such doses as have sometimes been prescribed you may easily comprehend that accumulations may occur and produce their disastrous effects after the circulation becomes more natural.

Regarding alcoholic stimulants, no physician can for the first time approach a person who is lying prostrate with cholera in the period of collapse, pulseless or nearly so, his hands and face cold, his countenance leaden, his features pinched, and not have suggested to his mind some powerful stimulant to restore force to the heart and quicken the sluggish currents of the circulation. Stimulants have been used with great freedom, and without going into details I will state that except in small quantities, in the initiatory diarrhœa, or possibly when injected into the bowels, the general view is that they are not serviceable, that they cannot accomplish any good results.

Next, is blood-letting beneficial? One of the first plans of treatment, both in India and in Europe, was to bleed the patient whether early or late. From what you already know of the condition of the circulation in the later stages of cholera, you will comprehend that bleeding is difficult in most instances; often a vein is opened and no blood will flow, and no rubbing of the arm, no warming of the patient, will induce it to flow in any considerable quantity. Under other circum-

stances it is noticed to flow with moderate force, and in moderate quantity, but always comparatively slowly; and it is always dark in color. Bleeding in the early stages will, of course, approach more and more nearly to bleeding as practised upon a healthy person, and it has been practised in all stages of this disease. I have made a succinct record of certain facts calculated by Drs. Baly and Gull in their valuable report, which I will read. Dr. Brown tried bleeding on the recommendation of the physicians of India, but found its effects invariably pernicious. Observe how this statement contrasts with the next. Dr. Strange says that in many cases of approaching collapse, all the symptoms yielded after a bleeding of from eight to sixteen ounces, followed by iron and quinine. What are you going to do with testimony so conflicting? Call other witnesses and let them tell what they have seen. Dr. Muller, of Riga, reports four persons bled while the pulse was still marked at the wrist, though feeble. Increasing collapse followed immediately, and all died. In ten persons, after from eight to ten ounces had been taken in full collapse, in only three were the patients made decidedly worse. Out of twenty-three others, after bleeding there was a favorable change in eight; but in most there was increased debility, full collapse, and death. In the Nicolai hospital six were bled, and five fell into coma and died. One recovered, he was in the first stage. Dr. Zeroni bled nine in collapse or impending collapse, and but one recovered, and he was bled but four ounces. Several of the bleedings were small. Mr. Bell is an advocate for bleeding, and here are his figures. Bled forty-four in the first stage, seven died; bled six on the verge of collapse, all died; bled nine in collapse, and seven died. And yet Mr. Bell is an advocate for bleeding. Dr. Haycraft relates a case of severe cholera in which cups applied unexpectedly drew eight ounces of blood; the patient felt immediately relieved, but died five minutes afterwards. In the consecutive fever even it seems the abstraction of blood is pernicious, or at least must be practised with a great deal of caution. In sixty-nine cases treated by depletion, local or general, Dr. Muller records forty-eight deaths. Even in the pneumonia of reaction, where, if anywhere, you would suppose it possible to bleed with advantage, there is the following record: Of eighteen cases of pneumonia, in the consecutive fever, six treated by bleeding all died; while of twelve not bled, five died and seven recovered. On such showings as these, blood-letting has pretty generally fallen into discredit. Mr. Bell lost, in forty-four cases of preliminary diarrhœa, seven. This is certainly more than I should desire you to expect to lose by milder treatment.

Before leaving this topic I must not fail to say that Dr. Geo. Johnson, to whose opinions on the pathology of cholera I have already called your attention, appears within the present year as an advocate for bleeding, and he quotes from physicians of India ("Notes," etc., p. 20 and onward) a very eloquent defence of the practice even in extreme collapse. He does not urge it as an eliminative measure, but he says, "by lessening the over-distension of the cavities of the heart, it increases the contractive power of their walls. The symptom which appears to call for venesection and which has most commonly been relieved by it, is rapid breathing, with an oppressive sense of suffocation. When, with these symptoms, there is a cessation of vomiting and purging, which is probably a result of the almost complete arrest of the blood in the lungs, I believe that venesection affords the only hope of benefit. If during the last epidemic I had known as much of the essential cause of collapse as I now do, I believe I could have saved some patients, who for the want of that knowledge were lost." Whatever may be said of this theoretical argument for bleeding under particular circumstances, it is clear that the good results, reported by the physicians of India in its indiscriminate use, have not been confirmed in Europe, while among the authors in this country I do not remember a single advocate of it.

Among the drugs used in the treatment of cholera, calomel has figured more conspicuously, I had almost said, than all other medicines put together. I shall have to take a little time to give you a correct view of the whole matter. It has been given in small doses and in large doses. Dr. Pereira, in the first edition of his Materia Medica, refers to the treatment of cholera by one of his personal friends in St. George's Hospital, who lost none, or next to none, when he gave drachm doses of calomel. Nobody, so far as I can discover, has been able to repeat that success. I have tried it and have failed. I have not had any "luck" with calomel in any mode of administering it. Some of you are acquainted with my views of the abuses of calomel. I regard it, not as an enemy to man, but as an agent that can be used less than it is with advantage to man.

With reference to the administration of it in large doses, it is reported that this drug was given in Charity Hospital, New Orleans, in 1849, to one patient fifty grains, repeating it in two hours; to another ninety grains in three doses, within four hours; to another, one hundred and twenty grains in one dose; to another, one hundred and fifty in one dose; to another, one hundred and eighty in one dose; and to two others, two hundred and forty grains, or half an ounce, in a single dose. This is sufficiently heroic. Ten patients were treated in this way. Four of these ten were in collapse, but not pulseless, when the treatment was begun; they all died. Six were not regarded as in any very great danger; of these, one died and two were badly salivated. The treatment did not in any single instance check the purging or vomiting. Dr. Buell reports, that of the five cholera hospitals in New York in 1854, the treatment in one was by large doses of calomel, I suppose sixty grain doses, and the result, he states, was that ninety-three and a fraction in the hundred of the patients died; being, he says, the largest mortality that occurred in any hospital in the city. Dr. Houston, in the paper I have already quoted, says he saw a recovery from the middle period of the second stage of cholera "under the weight of an ounce and a quarter of calomel in three doses, given within twelve hours." Generally, when physicians have tried these large doses of calomel, they have abandoned them. You will hear something more on this subject, as I go on to speak of what is called Ayre's treatment.

Dr. Ayre urges the use of calomel in *small and frequently repeated doses*. His opinions and plan are so generally known to the profession, and by many received with so much favor, that it becomes us to make a little inquiry into the success of that plan. That you may understand it, I will read you in his own language the doctrine upon which he rests his particular views:

"Cholera morbus (meaning Asiatic cholera) consists," he says, "in an interruption, and in its malignant form, in a sudden and entire cessation of the secretion of the liver; and primarily as a result of it, of a congestion of the portal circle or secondary system of veins of the liver; and in the malignant kind, successively of those veins of the abdominal viscera, and of the vertebral column, whose venous circulation is associated with them."

"The congestion of these important systems of veins becomes the cause of a diminution, and, in the malignant type of the complaint, of an entire suppression of the secretion of the kidneys," etc.

"The suppressed secretion of the liver forms the essence of the disease, the restoration of this secretion forms the remedy for it, and the agent by which this is to be produced must act upon the stomach and immediately through it upon the liver."

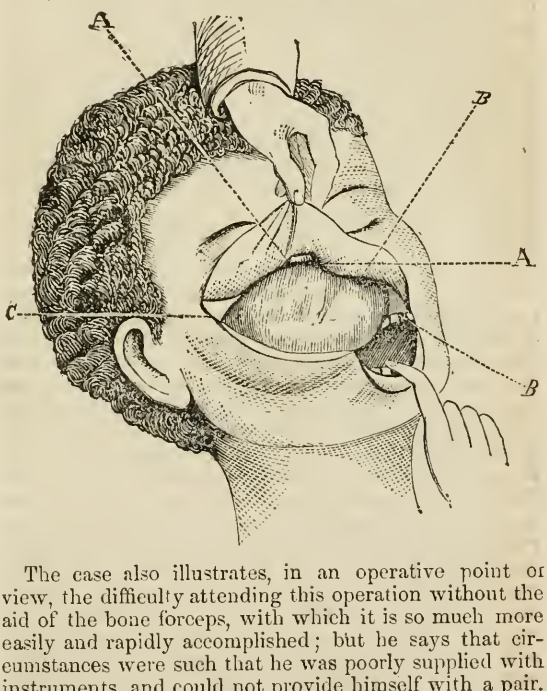
Now, is this a correct reading of the facts? In the first place, is it true that there is a suspension of the secretion of the liver? Certainly, there is no claim that there is any such suspension, or even diminution, during the preliminary stage. That stage is characterized as "bilious diarrhœa." During the rice-water discharges, I have already told you what is the fact—that bile exists in the discharges, but not in its usual form; it does not answer the common tests; it has undergone some change, but is still recognised by Professors Parkes and Simon as bile, which has undergone no other modification than is common in typhoid fever, and occasional in persons who make no complaint of illness. There is still bile there, except only during the very height of the disease. If suspension, or diminished secretion of the bile, is essential to cholera, it must begin at the beginning of the disease. That does not seem to be the fact. Then, again, as to hepatic congestion; you will perhaps recollect what has already been stated upon this point. The liver, as found after death, is *not* congested, but often quite exsanguinated. As to bile, I have referred to the fact, that after death the gall-bladder is found well filled, and sometimes greatly distended, and that its contents are, for the most part, apparently healthy bile. It stains the diphtheritic patches on the intestinal mucous membrane. The basis, then, of this system does not seem to be stable. Dr. Ayre gives calomel in the preliminary stage in doses of one grain with two or three drops of laudanum hourly, or every half hour, six or eight times; then every six or twelve hours. In collapse, one grain is made into a pill with bread, rubbed into a mucilage with gum arabic, in such quantity, that when dry, the pill will weigh a grain and a half. Such a pill is to be given every five minutes, and with it one drop of laudanum, or of the sedative liquor, in a teaspoonful of cold water. In severe cases, two grains may be given every five minutes for an hour or two. Dr. Ayre, in reporting upon his success, states that he has treated 3,039 persons affected with the preliminary diarrhœa, and with impending collapse, 133 being in the latter condition, and had lost only six of these. In full collapse, he has treated 725, of whom 365 died. Dr. Gull has collected the opinions of a considerable number of physicians who have depended on calomel as their chief remedy, a few following Dr. Ayre's plan strictly. Thus, Dr. Oke treated forty cases by it, and found that in children it was successful, and among adults in collapse, he saved about one-third. Dr. Merry, out of 52 cases, thinks he has saved forty by Dr. Ayre's plan, somewhat modified. Dr. Chambers has had 30 cases and eighteen recoveries; but he gives the calomel, five grains at first, and then two grains every half hour. Dr. Shillitoe has tried the plan, and doubts it and all other plans. Mr. Taylor, of the Liverpool Fever Hospital, thinks it is the best treatment in the serous diarrhœa. Mr. Perry approves Dr. Ayre's plan, but prefers to omit the narcotic; he, however, found nothing efficacious when the collapse had fairly set in. Mr. Roberts had 11 cases and eight recoveries. Three of these patients were moribund, or apparently so, when first seen. Dr. Shapter thinks, that on the whole this plan of treatment leads to less fatality than any other. Dr. Statter had 19 cases and eleven deaths. Calomel was tried in all, more or less. Ayre's plan failed with him. Mr. Mallet gave calomel in small and large doses, but all in vain. Dr. Wood tried calomel in large and small doses without satisfactory results; he did not see the advantage of the plan. Mr. Hovell tried it, in small and frequent doses partially, but with no good results. Mr. Brainbridge tried Dr. Ayre's plan in 3 cases; all died. Dr. Lewis tried small and large doses, but it was totally useless. Dr. Davies, prepossessed in favor of the plan, gave calomel in two and a half grain doses, and nine out of 10 died; he then combined it with opium and camphor, and in 33 cases twenty-four died. Dr. Parkes tried a similar plan in India, and found it of no use; he tried Dr. Ayre's plan in a few cases without striking benefit. Large doses, in his view, were hurtful. Dr. Raynor could not save his patients in collapse, by Ayre's plan, but thought the collapse prolonged. Dr. Barclay had 8 cases and five deaths. Of the three recoveries two were mild. Dr. Reid had tried Ayre's plan faithfully in 7 cases, and all of them died. Dr. Hill had applied Ayre's plan, to the letter, in 12 cases, and had had twelve deaths. Dr. Blackall gave calomel, in five grain doses, to 52 patients, the interval generally half an hour, in ten cases a quarter of an hour, in three an hour, and in two cases two hours: to 14 others he gave twenty grains every half hour, to 1 ten grains, and to 1 thirty grains every three hours; fifteen were not in collapse, and fourteen of them recovered; fourteen were in slight collapse, and twelve recovered; twenty-three in marked but moderate collapse, eleven recovered; eighteen were in extreme collapse, two recovered, and sixteen died. Dr. Fearnside treated 10 cases with small doses, four died and five recovered; among the latter, two were very mild; one was salivated. At Melville Hospital, Dr. Ayre's plan was strictly followed in 4 cases; they all died. Mr. Livett treated 9 cases with small and frequent doses, combined with a small proportion of opium; all, but a boy of fourteen, died. Dr. Shapter's 11 cases, treated with small doses, gave six favorable results. Mr. Williams treated 16 cases principally with calomel, twelve died. I have omitted most of the instances of Dr. Gull's list in which treatment by calomel was combined with other important agencies.

Figures are very uncertain guides in the treatment of such a disease as that we are studying, but, by their showing, in these statements, *calomel is not triumphant.* It holds the place it has heretofore occupied, in the treatment of cholera, by a very feeble tenure. Large doses are very generally condemned; small doses hardly get a majority vote. I am not willing to say that Dr. Ayre's plan must be abandoned. It has been tried and abandoned by some, because its benefits were not a compensation for the inconvenience to the patient of taking medicine so frequently. It has been tried and abandoned by others because it failed to cure. Yet, there are those who believe it will save more lives than any other mode of treatment. True, its theoretical foundations have crumbled, but many medicines maintain a high position in the list of remedies, and yet theory fails to explain their mode of action; Dr Ayre may have instituted a good plan of treatment on an untenable theory. The question, then, is on the merits of the plan. Is calomel serviceable in the treatment of cholera, however administered? It is remarkable, after the administration of countless pounds of this drug, in every conceivable way, in England, India, and this country, that the question cannot be positively answered. Dr. George Johnson believes that the medicine acts as a cathartic, and claims "the reported success of the calomel treatment as evidence in favor of elimination." Is the *reported success* worth claiming? If we ever learn the natural fatality of cholera uninfluenced by treatment, these questions may be intelligibly answered.

Progress of Medical Science.

Mortality of Children in Europe.—A paper was read at the last meeting of the Statistical Society of London, by Dr. W. Farr, F.R.S., on the "Mortality of Children in the Principal States of Europe." The proportion of English children, he said, who die in the first five years of age is very large, and one of the causes of this great loss of life, among the poorer classes especially, is want of care and attention by reason of the absence of the mother at work in the field or in the factory, often at the precise period when the child most needs constant looking after. Illegitimate children are, for obvious reasons, almost exclusively the victims of infanticide, but the number of deaths from that crime, he alleges, is inconsiderable in comparison with the number of untimely deaths from other causes. None of the States in Europe outside of England publish an account of the causes of death of the entire population, so no comparison can be made in that respect; but data have been obtained from official sources from which an accurate view of the loss of young lives in Europe from all causes can be given. The facts do not at all refer to the same period, but range variously from 1851 to 1863 in the different countries. The birth rate in Italy and Prussia is 39 per 1,000 of the whole population; Spain and Austria, 37; England, the Netherlands, Denmark, and Sweden, 34; Norway, 33; Belgium 30, and Spain, 26. The annual rate of mortality of children under five years of age, per 1,000 of the population of the same age, is in Norway 41; Sweden, 51; Denmark, 53; England, 68; Belgium, 75; France, 79; Prussia, 82; the Netherlands, 91; Austria, 104; Spain, 112, and Italy, 114. In England the mortality of children under five years of age is 101 in thirty large town districts, while in the sixty-three healthy districts of England it is only forty. Of 1,000 children born alive in Norway, 833 attain five years of age; in Denmark and Sweden, 797; in England, 736; in Belgium, 733; France, 711; Prussia, 683; the Netherlands, 673; Austria and Spain, 637; Italy, 606; Russia, 603; in the sixty-three healthy districts of England, 823; and in thirty large town districts of England, 645. Consequently the proportion of deaths out of 1,000 children born alive is in Norway 167; Denmark and Sweden, 203; England, 264; Belgium, 267; France, 289; Prussia, 317; the Netherlands, 327; Austria and Spain, 363; Italy, 394; Russia, 397; sixty-three healthy districts of England, 177; and in thirty large town districts of England, 355. The records of the peerage of England show that out of 100 children born alive in peers' families 90 survive, ten only dying in the first five years of age; and the deaths among the children of the English clergy are nearly in the same proportion. But in the foundling hospitals these proportions have been reversed; for 90 out of 100 born alive have been cut off in them during the first five years of life. By the English Life Table, of 100 children born alive fifteen die in the first year, five in the second, three in the third, two in the fourth, and one in the fifth—making twenty-six in the first five years. Of the fifteen who die in the first year five die in the first month of life, two in the second, and one in the third month. The French returns show the deaths in the first week of age, and the annual rate of mortality in that first week is 154 per cent., which may be thus illustrated: If 100 children just born were placed in a house, and their numbers maintained by the addition of a newly-born child to supply the place of every death, so that there should always be an average of 100 children maintained within the walls, 154 deaths would take place therein in twelve months on the hypothesis that the mortality rate be that of the first week of life.

Excision of the Superior Maxilla.—William R. Whitehead, M. D. (University of Paris), reports (*New York Medical Journal*, June, 1866), a case of excision of the superior maxilla, which offers several points of interest. One of these is the priority accorded to Dr. David L. Rogers of this city; but the chief and most interesting feature is the situation and peculiar nature of the tumor excised by Dr. Whitehead, and which from the microscopic examination seems to have been an osseous hypertrophy. It is so well exhibited by drawings that we take pleasure in publishing one of the excellent wood-cuts which has been placed at our service. In connexion with this operation he very properly alludes to Mott, Stevens, and other eminent American surgeons. The operation which furnished occasion for his paper was on a negro girl, twelve years of age, and was performed at the village of Anderson C. H., S. C., during the month of April, 1865.



The case also illustrates, in an operative point of view, the difficulty attending this operation without the aid of the bone forceps, with which it is so much more easily and rapidly accomplished; but he says that circumstances were such that he was poorly supplied with instruments, and could not provide himself with a pair. A single incision was made, such as practised by Liston, Syme, and others, and the tumor dissected from its contiguous tissues anteriorly. The facial artery, on account of hemorrhage, required a ligature to each of its cut ends; demonstrating one of the disadvantages of an incision in the middle of the cheek.

The os onguis was pierced with a trocar, and by means of a belloq canula and a threaded wire, a chain-saw was passed behind the nasal process and out at the anterior opening of the nasal fossa, and this process cut at the part indicated by the letters *A A* in the figure. An incision was made along the middle palatin suture, and another at right angles along the posterior border of the palate bone, and with the aid of the canula the chain-saw passed through the nasal fossa and the incision in the soft palate and out again at the mouth; the bony arch of the palate was then cut in a line corresponding with the middle palatine suture, and is designated by the dotted lines *B B*. A small straight saw was used to sever the malar bone and the upper

part of the superior maxilla, preserving the floor of the orbit. The tumor was wrenched out with strong forceps. There was no hemorrhage afterwards—five twisted sutures were used, and in seven or eight days removed—in a month the girl was entirely well. Six months afterwards there was no recurrence. He proposes in a subsequent article to treat of certain tumors of the superior maxilla.

Extrophy of the Bladder.—Dr. C. H. McGill, of Galveston, Texas, reports in the *Galveston Medical Journal* the following case of extrophy: The patient is a Texan, æt. 27; the bladder is situated in the median line, just above the symphysis pubis, where it forms an irregularly round convex tumor about four inches in length and three and a half inches in breadth. The tumor is soft and elastic, of a bright red appearance, is exceedingly sensitive, and bleeds readily on the least irritation. The size of the tumor is greatly influenced by the position of the patient, being much greater in the erect than in the horizontal position. It has a fungoid surface, and is traversed with fissures varying from one-eighth to one-fourth of an inch in depth. The urine seemed to exude from the entire surface of the tumor; more, however, from these numerous fissures. The mouths of the ureters could not be found. The penis was only one and a half inches in length, was without a glans, was imperforate, and was flattened by compression between the tumor above and the scrotum below. Although the testicles were of the ordinary size and healthy, the patient had never experienced sexual desire.

The Mortality Rate in Certain Towns of England.—While the annual rate of mortality for the whole of England is only 22 in a thousand, in Manchester it is, taking a ten years' average, 31, and in 1865 was 35.6. Mr. Leigh, a registrar of health, in a second paper to the registrar general of England, enters fully into the subject of the impurities of the atmosphere and its effects in that city. He divides the atmospheric impurities of towns, into solid, vesicular, and gaseous; shows that the first, which occupy the lower stratum, act as irritants to the respiratory organs; that the vesicular impurities, which form the medium, are direct excitants of many types of disease; while the purely gaseous enervate the system, and render it an easier prey. "Of the solid impurities," says Mr. Leigh, "the principal is coal smoke, which forms a continual dark and dense canopy over Manchester, and causes a murkiness in the streets from which they are never free." Mr. Leigh shows that the mean annual mortality for lung diseases is greater in Lancashire and Cheshire than in any other divisions of England, with the exception of London.

Presence of Sulphur in the Atmosphere.—Sulphur having been proved to be everywhere present in the air, it is now found to be accompanied by sulphate of soda, which is obtained under circumstances that would seem to settle the question.

The Temperature as affected by Altitude.—The temperature at 22,000 feet above the sea is about 72½° lower than at the surface, which gives, supposing the decrease to be uniform, a diminution of about 1° for every 315 feet.

Insalubrious Atmosphere in a Court Room.—A recent examination of the atmosphere in a certain court-room showed that 5,000 parts of oxygen were absent in each 1,000,000 of air, the only parallel to which, so far found, exists in the under galleries of coal mines.

Disinfection by Steam.—At a recent trial at Seguin's Point, Staten Island, steam superheated by an ingenious but somewhat rude apparatus, improvised by Dr. A. N. Bell, of Brooklyn, and Mr. L. W. Leeds, an engineer of Philadelphia, gave the following results: Eggs, oysters, and fish were cooked in five minutes; and in ten, eggs wrapped in eight folds of a soldier's blanket were made as hard as heat can make them. The highest temperature marked by the self-registering thermometer was two hundred and sixty degrees; the highest by the thermometer on the outside of the building was two hundred and twenty-five degrees. Preparations are going on for a trial of steam at an early day in infected houses in the city.

Production of Oxalic Acid.—Three French chemists—MM. Laurent, Castheler, and Basset—have succeeded in obtaining oxalic acid from the waste of shoemakers' and saddlers' shops and others, where leather is used; also from woollen rags, horn, hair, etc. For this purpose these residues are treated with one part of sulphuric acid and four of water, and the mass thus obtained is subjected to the action of one part of nitric acid and three of water, at a temperature of about eighty degrees centigrade. From the digestion of this, oxalic acid is easily extracted.

Treatment of Trichiniasis.—Dr. H. Keifer (*Detroit Review of Medicine and Pharmacy*) says: "I think the chief indications are, to support the patient by a nourishing diet, in order that, if possible, he may retain vitality enough to pass through the period while the entozoa are active, as, after they are incapsuled, they do comparatively little harm. All other treatment should be symptomatic and expectant."

Intra-Uterine Retention of Urine.—Depaul related to the Society of Biology a case of intra-uterine retention of urine, resulting from obliteration of the prostatic portion of the urethra. A male child, born in the eighth month, died soon after birth. The kidneys and ureters were enlarged, and together with the bladder contained 500 grm. of urine.—*Prag. Vertel Jahr. Schrift.*

Creasote in Diphtheria.—Dr. J. J. Knott, of Griffin, Ga. (*Atlanta Medical and Surgical Journal*), reports favorably upon the local application of creasote in diphtheria. The formula for the preparation he gives as follows: ℞. Creasoti ʒ ij.; Aq. Font. ℥ ij.; Pulv. Acaciæ q. s.

Bromide of Potassium in the Treatment of Acute Gonorrhœa.—Dr. W. H. White (*Med. and Surg. Monthly*, Memphis, Tenn.) recommends the use of this salt in the treatment of acute gonorrhœa. He affirms that it possesses the peculiar property of preventing chordee consequent upon nocturnal erections. When a case is presented in its first development he recommends its use in doses of five to eight grains three to six times during the succeeding 24 hours, in combination with saline cathartics, low diet, rest, and cold applications to the part. When the heat and acute pain and excitability are reduced, the remedy should be continued with some of the stimulating diuretics, together with the occasional use of mild astringent injections.

Bromide of Potassium for Irritable Urethra.—Hutchinson has used bromide of potash for irritable urethra in over thirty cases, with the most favorable results. This was particularly the case in inflammatory strictures of the urethra, in which the sensitiveness was rapidly diminished, and subsequent introduction of the catheter was followed by extensive dilatation. He calls attention to the similar anæsthetic action of the remedy on the fauces.—*Prag. Vertel Jahr. Schrift.*

SYSTEMATIC REGULATION OF MEDICAL STUDIES.

IN the last number we alluded to the advantages which would grow out of an extension of the lecture term, and took occasion to point out the evils which were inseparably connected with the present system of crowding both students and teachers. Pursuing the general discussion of these evils, we propose briefly to allude to the necessity of inaugurating other measures which are equally deserving of the attention of those who have the power and disposition to institute reforms.

Next in importance to the extension of the lecture term, and naturally growing out of it, is the systematic division of the medical class into grades that will respectively meet the requirements of the first, second, and third-course student. At present lectures upon any given subject are given promiscuously to one class, and the student of the first year sits beside the one who is receiving his third course; and each has to choose for himself what he thinks he can appropriate. The beginner bewilders himself with terms that he is not prepared to appreciate the meaning of, while the second and third-course students vainly strive to confine their attention to the most elementary subjects. Viewing the lectures as a whole, they are of great benefit to the class; for what will not suit one is sure to be just what the other may want. But this lack of system in the regulations of the student is most ruinous not only to his habits of thought, but to the disposition he may have to confine his attention strictly to those subjects which are fitted to his capacity. He is virtually left to himself to choose his own course; and without being under any special restraint from the faculty, can just as well take up the study of midwifery before he has a knowledge of the bones of the pelvis, as waste his misdirected energies upon surgical operations before he has grounded himin his anatomy. Such students, and these are very much in the majority, have a strange perversity for commencing at the tail end of their studies and working up. They can hardly be blamed for this either, as the subjects which they are led to prefer offer many more attractions for them than those which properly form the groundwork of their studies. The elementary branches are uninteresting to them, because they cannot see their practical application; and they place them aside "for a more convenient season," when, they persuade themselves, they shall be better able to relish them, really looking upon their studies as amusement rather than actual work.

This desultory mode of study is directly attributable to the want of a proper division of the work by the professors. It is true that the recommendations which each professor gives to the members of his class, as to the course that they should pursue, are sometimes heeded; but from the want of strict regulations to enforce such precepts, thorough instruction is shorn of one of its chief advantages.

There should be more than a mere recommendation to study such and such a branch, such and such years; the college should insist upon its enforcement.

The only way they can do this is to divide up the class into three separate ones; each class having its own branches for study, and no other. The elementary class should be composed of first-course students, the next highest of second-course, and the senior class of the third-course student. In order that each class should be fitted for a higher grade, they should be examined at the end of each term, and if not qualified, should be thrown back, to go over the course again.

This would entail some extra work upon the professors, but they should be willing to shoulder the burden on behalf of the student and for the interest of the college. The former would, by the proper regulation of his studies, take immense strides towards attaining the proper knowledge of his profession; while the latter would not be compelled to hazard its reputation by granting a license to practise merely on the results of the final examination.

In the matter of examinations we have another word to say. There is not enough communication between teacher and student; not enough of that interchange of thought which should belong to profitable instructions. Very many professors think if they have filled up their hour with a lecture, they have performed their duty to their hearers, and the latter have accustomed themselves to expect nothing more. If a student fails fully to understand his teacher, it is considered his misfortune; and there are at present no opportunities for him to have difficult points explained except he crowds around the lecturer at the end of the hour and is content with a hasty answer.

The difficulties which some students labor under in having proper facilities for the satisfactory elucidation of difficult questions are in the main very great, and the discouragements which grow out of them are of no inconsiderable moment. If each professor were to devote

one hour in each week for the examination of the lectures he has during that time given to his class, all these difficulties would be overcome. The student could then be questioned, and if he failed to comprehend any important point, he could have it explained him. These examinations should not be confined to a few members of the class, but all should be required to place their names upon the list. Not only would this plan assure the teacher that his instruction was beneficial, and give him a knowledge of the relative standing of individual members, but it would insure for him a strict attention to his lectures, and the taking of careful notes, a habit which, by the way, we cannot too strongly recommend to the student.

While endorsing the practicability of these changes, we are aware that they cannot be made at once; but this much at least can be done on the part of those colleges that may favor the project—viz. an announcement to the effect that after a certain period a plan founded upon such changes will be adopted. We would not presume to enter into a detailed account of what the arrangements of subjects for different courses should be, as we think such matters belong strictly to the colleges themselves. It is, however, desirable that such a plan should be as universal and as uniform as the particular circumstances of each college will admit, so that students changing from one to the other may not have their courses of instruction interrupted or confused.

The convention of medical teachers will doubtless deliberate upon the feasibility of making such changes as have been suggested, and the profession will await with no common interest their decision.

We have noticed of late a disposition in certain medical gentlemen to court notoriety in a way that strikes us as not only very unprofessional but in very bad taste. We now not unfrequently see a notice of a "very difficult and dangerous operation," performed by the very skilful Surgeon A; of a very learned and scientific lecture on some rare (?) form of disease, by Dr. B; of some astonishing recovery brought about by the assiduous attentions of the eminent Dr. C; and we cannot make ourselves believe that such reports can find their way to the public without the knowledge of the principals. The extent to which this system is now being carried on is shameful, and deserves the serious attention of some Committee on Medical Ethics. It may, perhaps, be that the public are particularly anxious to know of the exploits of Dr. A., the views of Dr. B., and the success of Dr. C.; but it does seem strange that some of the doings of *our really substantial* men are not alike so faithfully and regularly reported.

The anxiety of the public to know something of cholera has tempted many an otherwise prudent man into the indiscretion of addressing a letter on the subject to some of our leading papers. There would be some shadow of an excuse for this if these gentlemen could be considered authorities in the matter; but, unfortunately for us, their ideas are crude in the extreme, and while they may tend to glorify the writer, inevitably stultify the profession. If the public desire to have any authoritative opinions concerning this disease, they can appeal to the Health Board and be satisfied; it is the duty of this body to minister to the wants of the community in this respect; and, so far as we can see, they do their duty.

Medical men occupying public offices have a right to address the public, to whom they are expected to give an account of themselves; there may be instances too, where late incumbents may, from necessity, rush into print to defend views before mooted in public; but it strikes us as discreet, at least, for other members of the profession to wait until their opinion is sought for, and not to cheapen their otherwise valuable services by volunteering too much.

Reviews.

THE STUDENT'S BOOK OF CUTANEOUS MEDICINE AND DISEASES OF THE SKIN. By ERASMUS WILSON, F.R.S. New York: William Wood & Co. 1865. Pp. 445.

THIS new book on skin diseases, by Mr. Wilson, contains several changes in his views from those expressed in his former writings, prominent among which is his so-called "clinical arrangement," which is an attempt to classify affections of the skin "on the most salient and striking characters of each disease, whether those characters be in their nature pathological, etiological, or physiological." Twenty-two groups are thus made. The anatomy, physiology, and pathology of the skin are given in a very interesting manner in the first sixty-five pages. This will be found a very valuable portion of the book, not only to the student but also to the medical man who wishes to recall forgotten facts and illustrations.

The various diseases of the skin, beginning with the eczematous affections, in which, in accordance with his clinical classification, he places *eczema*, *psoriasis*, *pityriasis*, *lichen*, *impetigo*, *scabies*, and *gutta rosacea*, are then discussed in a very readable manner to the end of the book. We confess to a great liking for Mr. Wilson's views in general, especially his careful observations of the state of the general health in affections of the skin. His views have been so far modified by the teachings of *Hebra* and his school, that he now gives local treatment its proper place, while he has not adopted what it seems to us is an erroneous view among German special teachers; that is, the one which ignores the constitutional state, which in many classes of cases seems to be the primary cause of the local manifestation.

An Appendix is added, in which Hebra's classification of cutaneous diseases is given.

Without pretending to render any judgment as to the respective merits of the various systems of classification over which the writers on cutaneous medicine make such an ado, we may commend Mr. Wilson's book as an able and interesting one, and as containing a system of treatment which has proved successful. The publishers have presented the work in a very creditable manner.

I. Cheloid. II. Frost-Bite. III. Compound Fracture of Femur: Union without Shortening. IV. Simple Fracture of Femur. V. Periostitis: Incision. VI. Fracture of Leg, and Apoplexy.

Reported by John Winslow, M.D.

Wednesday, January 10, 1866.

I. *Cheloid.*—Richard N——, æt. 21, has no evidence of strumous or syphilitic taint, hereditary or acquired. He is temperate, and has always enjoyed perfect health, with the exception of this affection. About one year ago, he first observed small, white, tuberculous elevations upon the skin of the præ-sternal region. These disappeared after two months, and a month later reappeared, steadily increasing until about four months ago, from which time there has been little or no change. The eruption presented itself also, but much less abundantly, upon the back. You will now observe, all around the margin of this mass of cheloid tissue, very many of these little white tubercles, about the size of a split pea. This is the first stage of the eruption. Towards the centre they have become conical, and run together, and in this manner have been formed long, elevated ridges, firm, but slightly elastic, smooth, of a pale pink hue, closely resembling the wheals arising from the strokes of a rod. The change in color occurs after the tubercles have become confluent. The cheloid masses move freely upon the tissues beneath. The patient complains, especially when perspiring, of sharp itching, smarting, and burning in the part, which phenomena are characteristic of this affection. He mentions also a pain in his side, which, I presume, is merely sympathetic, as there is no cough or other evidence of thoracic disorder.

The intimate structure of this growth is found to be essentially the same as that of a fibro-plastic tumor. But the cheloid limits itself to the tegumentary tissue, and it is multiple, or formed of many separate points of deposit, which eventually coalesce; while the "fibro-plastic tumors," so called, may appear elsewhere, and are commonly single. Under the microscope, fibrous-tissue filaments are seen crossing each other in all directions, and inclosing a small amount of plastic matter. This growth is very slightly vascular, the pink color, now observed on some of the masses, being wholly superficial. In its tendency to return, it may be classed with the fibroid recurrent tumors; but, unlike them, it is indisposed to ulcerate or to become malignant, and is not likely to produce more serious consequences than the attendant irritation and annoyance. It may occur idiopathically, and then is apt to begin upon the breast; but it is oftener traumatic. It is most frequent after burns, the cicatrix of which it resembles; but it may follow a mere scratch. It is said to be more common in the negro than in the white man.

Once established, cheloid is persistent, even the transient disappearance noted in the present instance being quite unusual. It may, however, continue through life with little or no increase either in extent or in severity. Our treatment must, therefore, be palliative, and not remedial. No authentic case has come to my knowledge of the successful extirpation of the disease by excision, even where the mass of morbid tissue has been small. It is certain to return in the cicatrix. Again, we have no specific, constitutional remedy. Many drugs, particularly the arsenicals, have been tried, with no benefit beyond occasional palliation. We may expect to moderate the irritation by attention to the general health, keeping the bowels free by saline aperients, and avoiding violent exercise or undue excitement. Low diet is not indicated, unless by some temporary inflammatory action. In the case before us, collodion has been applied by Dr. Farrell, the House Surgeon, with the double purpose of protecting the parts from the chafing of the clothes, and of possibly reducing the size of the elevations. The patient is taking *Liq. Potas. Arsenit.* gtt. vj., *bis in die*, to test its effect; but we expect no advantage from it.

II. *Frost-Bite.*—These severely cold days have furnished many cases of frost-bite. In the man before us, a driver of a Broadway stage, the fingers of the right hand have been badly frosted. The very dark purple color at their ends indicates death of the skin, but probably not of the deeper tissues; above this you notice a number of vesicles; the parts are numb, and cold to the touch. The patient states that at the time of exposure he had no pain, but only loss of sensation. He has reason to think he made a complete trip after his fingers were frozen, before suspecting the fact, his hands feeling, as he declares, "rather warm."

We see here the local effects of cold. Its constitutional action is familiar, and was especially well observed in Napoleon's Russian campaign. It is that of a direct sedative, producing symptoms similar to those from a narcotic dose of opium. There is an overpowering lassitude and desire to sleep, which, if indulged, ends in loss of consciousness and a speedy and painless death. So also the destruction of a part may be the result of the direct sedative effect of the cold; but it is more commonly due to the violence of the subsequent reaction. The proper treatment is, then, to make this reaction as gradual as possible. We apply cold water, not on the homœopathic principle of *similia similibus curantur*, but because cold water is really warmer than the congealed tissues. Snow is not always safe, as it may be too cold; and rubbing with snow, or with anything else, is objectionable, both from its tendency to excite inflammation, and from the danger of breaking parts made brittle by frost. This accident is said to have happened sometimes, especially in the case of the ear. If the patient exposes the frozen limbs to the fire, the reaction will be so violent that not only will sphacelus be insured, but fatal congestion of the lungs may ensue.

The fever consequent upon exposure to cold is generally of a typhoid form; and the inflammation of frost-bitten parts in most cases assumes an erysipelatous character. Stimulation is, under these circumstances, proper and necessary. This is another illustration of the principle that we must not treat affections by their names, in accordance with preconceived theories, but we must be guided alone by experience. Where deep sloughing is clearly inevitable, a yeast poultice is one of the best applications. In milder cases I am fond of the *Ceratum Resinæ* (Unguentum Basilicon), which is gently stimulant, and therefore well suited to inflammations of this nature.

III. *Compound Fracture of Femur: Union without Shortening.*—John B——, æt. 4, whom we call our "Young Napoleon," suffered compound fracture of middle third of left femur, 25th Aug., 1865, from being run over by a wagon. He was received into hospital directly after the injury. Under the extension of four or five pounds, with no side splints (I do not recommend this omission), union has been effected without shortening. But here, upon the inside of the thigh, is a sinus evidently leading to necrosed bone, and I feel

a sequestrum apparently ready for removal. We will etherize the little fellow and explore more thoroughly.

Children take ether or chloroform very kindly, and the sleep so induced is quite natural. I have never known a fatal result from their administration to children of less than eight or ten years. I once attempted to give a child chloroform while asleep, but did not succeed. I would like to see the matter further tested, as I am quite sceptical in regard to the stories of robbery thus committed, though I do not absolutely deny their possibility.

The sequestrum proves to be large, and is still firmly attached to the upper end of the lower fragment. In such a case it becomes our duty to leave it, as its violent removal would probably be not only fruitless but injurious. The limit of necrosis being yet undefined, we might cut below or above it. If above, we should do no good; if below, we should sacrifice sound bone, and predispose the part so irritated to inflammation and further necrosis. So long as the patient is doing well, leave the case to nature, and wait until the dead bone has separated from the living. Then the exfoliated portion may, in most cases, be easily removed; yet it is occasionally required to cut through living bone to reach it.

Understand, however, that we should be chary of even the slightest interference while the patient is debilitated and surrounded by hospital miasmata. I remember removing, by an incision three-fourths of an inch long, and with the loss of not above two drachms of blood, a loose sequestrum from the thigh of a Confederate soldier. The next morning erysipelas appeared in the wound, and the man died. With this experience fresh in my mind, I counselled against removing a similar sequestrum from the tibia; but it was done, in opposition to my advice, and fatal gangrene followed. The same considerations apply still more strongly to amputations and resections. At Williamsburg, every one of fourteen resections of the shaft of the femur, made under similar circumstances, ended fatally. I have not always thought these lessons necessary. But the fearfully lengthening death-roll of the hospitals in the early years of the war, convinced me that it was quite impossible for surgeons, without experience in large hospitals, to realize the baneful influences which here surround our patients. Happily the last four years have not been barren of instruction to our profession. Let us remember the lessons.

IV. *Simple Fracture of Femur.*—John O'B——, æt. 9, Irish, admitted Jan'y 2, 1866, with simple fracture of right femur, middle third. The case was treated, like the last, with Buck's apparatus. At first six pounds extension was applied, afterwards ten, with counter-extension by the weight of the body upon the bed, and no side-splints. As the result of this treatment, we had the limb straight, but shortened three-fourths of an inch. The extension was then increased to thirteen pounds, with counter-extension by perinæal band, and side-splints were applied; from which we have already a gain of about three-eighths of an inch. The side-splints I deem important, though they may in some cases (as III.) be dispensed with. The perinæal band is advisable for children, whose muscles are strong in proportion to their weight, and who will not lie quietly upon the bed.

Any shortening not exceeding an inch would produce no apparent deformity in a child of this age. The pelvis and the lumbar vertebræ would in a few years so accommodate themselves to the new conditions as completely to conceal the defect, both in gait and attitude. Indeed, it is hardly observable now. The feet are exactly opposite each other, and so are the knees; but the right ilium is higher than the left. The mode of measurement is of consequence. Velpeau measures from the fold of the groin; but the two folds may show a difference in position of two or three lines. Measurement from the centre of the sternum is subject to various sources of error. I formerly took as my point of departure the anterior superior spinous process of the ilium, marking the skin with ink or iodine; but found it very difficult to make the results of two trials agree precisely. The small tubercle just below this process, at the origin of the tensor vaginæ femoris, furnishes a definite point; and I measure thence, to my finger-nail placed immediately below one of the malleoli. This is the only plan I consider trustworthy, and by it the variation in several trials may be less than a line.

Looking over ninety cases of gunshot fracture of the femur, I find some straight, some crooked, all shortened —the average shortening being about two inches. The best results have been obtained from the straight position.

V. *Periostitis: Incision.*—Margaret D——, æt. 28, domestic, was transferred from the medical ward, having suffered intense pain in the left thigh for several weeks. Periosteal inflammation was diagnosticated; and, on the 9th of December, to relieve the tension of the inflamed parts, a deep incision, six inches long, was made upon the external aspect of the thigh. The femur was found rough, its periosteum being partially separated. The agonizing pain was at once relieved; but the effects of its long continuance, as well as those of the periosteal affection, upon the system were not so easily overcome. The patient was extremely weak, and so continues, showing also a tendency to nausea that has led me to fear pyæmia. She has had a number of slight rigors, but none well marked; and she is gradually improving.

Callus (an involucrum) has begun to be secreted about the diseased bone. I anticipate more or less exfoliation from the parts whence the periosteum is detached. Where this is torn off from sound bone, as is sometimes done in trephining, exfoliation may not occur; but I think it always follows when the bone is diseased.

VI. *The Apoplectic* patient (case IV. of 8th inst.), with fracture of the leg, is dead. This was a case where the inflammation of the ankle-joint, near the point of fracture, was so great as to preclude the use of even the slightest extension; and at no time did the council of surgeons consider him in fit condition for amputation.

The Criminality and Frequency of Abortion.—At the twenty-sixth annual meeting of the Hampden County Massachusetts District Medical Society recently held, the following resolutions relative to the alarming increase of the crime of abortion were unanimously adopted:—

Whereas criminal abortion has become an alarming evil by its frequency in society; and

Whereas many suppose it to be a crime of little magnitude,

Resolved, That we deem it our duty to society, to publicly express our opinion of its nature and criminality, and also the detestation in which we hold all who may in any way abet the crime.

Resolved, That we regard the unwarrantable taking of life of the unborn fœtus at any time after conception, in a moral sense, as much the crime of murder as to destroy the infant at full term.

Dr. Edward L. Beadle, late of this city, has been appointed President of the Board of Health of the city of Poughkeepsie, where he now resides. We congratulate the citizens of Poughkeepsie on this most judicious appointment.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

STATED MEETING, JUNE 20, 1866.

DR. JAMES ANDERSON, President, in the Chair.

LAMINARIA DIGITATA.

DR. WORSTER presented specimens of the *Laminaria digitata*, or Sea-tangle, from the Bay of Fundy, where it may be found in abundance at a very low tide point in the protected coves He claimed a superiority over the English article, which, owing to its brittleness, is fast going out of the market, while these specimens possessed not the bad fetor of the compressed sponge, and were as tough as rope-yarn. The *Laminaria digitata* is for the most part derived from the Straits of Magellan, the British Channel, and in this instance the Bay of Fundy. For all practical purposes, no variety had given him the satisfaction of the last mentioned.

THE PREVENTION OF EPIDEMIC CHOLERA.

DR. HARRIS presented a series of resolutions* for the prevention of Epidemic Cholera.

DR. POST moved that the resolutions be considered *seriatim*, whereupon the preamble and first resolution were carried unanimously.

DR. HERZOG contended that the language of the second resolution was faulty, in that no expression was given to the fact that the choleraic excretions, to produce mischief, must be in contact with the soil, the linen, or some agent capable of producing fermentation.

DR. HARRIS explained that, although he agreed in the main with the last speaker, he had been careful, in the framing of the resolutions, not to endorse any theory, however ingenious; and that his object was to construct a platform upon which the whole profession might stand. With this end in view, he had refrained from introducing any reference to questions of temperature, moisture, etc., in so far as their operation upon organic materials was concerned. Pettenkofer's views were not yet adopted as a whole by the profession; the evidence was yet to be sifted, the facts to be reviewed and tested.

DR. HERZOG maintained that, as a scientific body, the Academy should express scientific facts; and that even theories, when strengthened by experiments, afforded a certain amount of knowledge worthy of expression, if not endorsement. He would therefore favor a remodelling of the language, if for no other reason than to inspire confidence. He contended that knowledge was limited in more instances than the question now being discussed; that a mere vesicle gave no clue to the character of the virus it inclosed; that conviction came only after the disease had manifested itself by its behavior, effects, etc. Choleralogists had agreed that there was no specific difference between spasmodic and Asiatic cholera; and what was true of the one was also of the other.

DR. SAYRE expressed the view that there was a difference between the American and Asiatic cholera; that the former was not capable of propagation, while the latter was. He would conjure Dr. Harris to put down his conditions and defend them with courage.

DR. HARRIS averred that caution in the use of words was as essential as courage; that too much might be said as well as too little, and cited Professor Parkes and Dr. Wm. Budd, of England, as authorities in the support of his position. He would, however, amend the text in dispute so as to read as follows:—"That the choleraic diarrhœa and 'rice-water' discharges of cholera patients are capable (*in connexion with well known localizing conditions*) of propagating the cholera poison," etc., etc.

The amendment was agreed to, and the resolution as a whole adopted.

The third resolution, relating to the danger of personal attendance upon the sick and the controllability of the causes of cholera, was then adopted without debate.

The fourth resolution enjoined thorough cleansing and disinfection of persons and clothing. Carried.

The fifth read as follows:

"*Resolved*, That for the purposes here mentioned, an external sanitary police is desirable in all great maritime and river towns, but that such sanitary regulations need not seriously embarrass commercial intercourse and the interests of trade."

DR. SAYRE said that it was necessary that definite views, as emanating from responsible bodies, should be extensively circulated. He could not but condemn the action of the Board of Consulting Physicians in Boston, Mass., to whom he had sent facts incontrovertible, with the result of finding them ignored, and such phrases as these adopted in the room of logical conclusions: the Board regrets the "change of views" on the part of Dr. Reid, "the cholera cannot be barred out," it "comes through the atmosphere," and was a "something upon the people." Such high authority should be met, otherwise vague deductions would take the place of positive knowledge.

DR. HERZOG pronounced quarantine to be the true safety-valve. Periods of variable length had been adopted by different authorities, extending from ten to twenty-two days; the International Quarantine Convention, for instance, had fixed upon fifteen days as the limit. There could be no doubt that a certain time for incubation was necessary, but the time embraced by it had not yet been very accurately determined. Dr. Pettenkofer, indeed, had opposed quarantine regulations, owing to the difficulty of rendering them effective.

DR. SAYRE said that Dr. Pettenkofer did not oppose the *principle* of quarantine; but, on the contrary, was a firm believer in it.

DR. HERZOG, in further elucidation of his views regarding the incubation of the disease, gave the history of the origin of the epidemic upon Ward's Island. He said that it had been brought from the "Atalanta," by a nurse who had been ten days aboard of the vessel, and had been admitted into the State Emigrant Hospital for a sore foot, where he remained five days. The cholera manifested itself six days after this patient's departure.

DR. HARRIS, without defining the nature of cholera, said that quarantine had saved Rome; but Rome was to-day worse off for the infliction, if the accounts of privations, etc., as given by those then sojourning there, be accepted. He did not hold that quarantines, as at present conducted, should be regarded as blessings; and yet the Board of Health were obliged to shoulder the whole responsibility.

DR. SAYRE thought Dr. Harris somewhat inconsistent. If quarantines were useless and could not be enforced, why not abolish them at once. Again, if quarantines were only pest-holes, from which leakages were to constantly occur, they should by all means be abandoned; if no good resulted, commerce should not, of course, suffer.

DR. HARRIS suspected that the cases which had recently occurred in the city were traceable to infected clothing from the cholera ships; a quantity small, to be

* These resolutions were published in the preceding number, p. 223.

sure, but sufficient for mischief, may readily have been introduced into the city after escaping the vigilance of officials. Such clothing would most likely be found in Pitt, Willett, and like streets of that section of the city. He would cite as a probable corroboration the case of the patient in Thirty-fifth stree', who was seized with the disease after a visit to that quarter.

The resolution was then, on motion, adopted.

The sixth resolution, expressive of confidence in the protecting influences of "sanitary measures, municipal, domestic, and personal;" and the seventh, inviting the profession in general, wherever dispersed, "to urge the immediate adoption of adequate measures of sanitary protection," were, on motion, severally adopted as the sense of the Academy.

Dr. Bell (of Brooklyn) made some remarks upon *steam disinfection*, in which he gave an account of the results of experiments at Seguin's Point.

Dr. Bulkley had recently seen an apparatus for superheating steam, where the steam was also dry.

Dr. Hamilton moved that Dr. Bell be requested to report on that subject to the Academy at the next meeting. Carried.

DEBATE ON THE RESOLUTION ENDORSING THE HEALTH BOARD.

Dr. Sayre remarked that his previous motion, calling for a reconsideration of such part of the minutes of a past meeting as related to the resolution endorsing the Health Board, was now in order. As illustrating the sense of the profession at large and the interest excited by this action of the Academy in a neighboring city, he quoted at length an article from the *Medical and Surgical Reporter*, Vol. XIV., page 474, under the caption of "The Metropolitan Board of Health and the Academy of Medicine; a point of Ethics." He fully endorsed its sentiments, and adverted to a former action of the Academy, by which, as a body, they voted to withdraw all official and professional intercourse with the respective heads of the Medical Bureaus, should the so-called system of Homœopathy be recognised in the appointments then to be made. In the present instance, according to the secular press—and the reports all agree, at least they have not been denied—"Homœopathic" appointments have been actually made. He hoped that the Academy would not jeopardize its standing with the American Medical Association, by allowing the minutes to stand as at present recorded.

Dr. Post stated that this resolution was intended to offer the coöperation of the Academy to the Health Board, only so far as sanitary measures were concerned. Still, if the language of the resolution were open to misconstruction, and to the charge of endorsing Homœopathy by implication, he would make the sense of the meeting clearer by offering a supplementary resolution disclaiming any such intention. The resolution, thus amended, was then offered.

Dr. Hamilton said that the medical members of the Health Board had been simply outvoted, and that all of the gentlemen in question were well known as being opposed to Homœopathy.

Dr. Sayre replied that it was essential that the record of the Academy, as far as this question was concerned, should be *preëminently* clear. These homœopaths, rejoicing in their seeming triumph, claim to have been endorsed by the Academy, and would with this seeming endorsement be more clamorous than ever for recognition in all Hospital appointments.

He questioned the honesty of the phrase as substantially used by Dr. Stone; looking to the conciliation of popular prejudice; it was the duty of every member of the profession, however humble, to be true to himself in his conflict with error. Dr. Parker has said before the Health Board that he at times practised homœopathy also, and besides all this, some claim that he has even allowed it to be practised in his own family.

Dr. Hubbard stated, in vindication of Dr. Parker, that the circumstance which originated one of the reports, arose in this way: Dr. P. had, it is true, allowed a homœopathic practitioner the charge of his child soon after his arrival in the city. He desired to put to the test the homœopathic boast that hooping-cough was curable by their treatment. One of these practitioners was exchanged for another, with the result of merely confirming Dr. Parker's incredulity regarding "the potencies." He stated this on the authority of Dr. Parker himself, with whom he had conversed in regard to the matter.

Dr. Hamilton was convinced that Dr. Parker's language before the Board, to the effect that "he practised homœopathy," had been misconstrued; that he believed his intention was to convey the idea that in certain cases he (Dr. P.) also practised homœopathy, in the sense of non-interference, when the case demanded it.

Dr. Bibbins inquired whether, or not, the Academy was inclined to homœopathy? If not, then let the contrary be *distinctly* stated. When one yields out of respect to the prejudices of others, can he act according to his own convictions of right; nay more, can he claim our confidence? Why may not Dr. Stone, with equal propriety, give Dr. Newton, who cures "by the laying on of hands," an opportunity of testing his system also? Dr. Newton can boast of throngs, where we can claim individuals only. Surely here this is enough manifestation of this self-same "popular prejudice;" why not then, by a parity of reasoning, place him in a position to exercise his remarkable power? Give every therapeutical plan an equal chance, for all have advocates, more or less numerous. We find Drs. Parker and Stone mingling in the debate at the second meeting of the Board: "Let us try it," say they; "if it be the proper practice, let us practise it ourselves." Are not these doubts almost admissions? Again, is the Board anything more than a political body; and has the Academy ever before made haste to endorse any similar corporation? When it changes its political complexion, what then? Other men of other medical creeds may be appointed; it may be politic to do so; there may be other combinations; a different administration of affairs may supplant the present, for such is the history of all political bodies. As citizens do not expect the Board of Excise to concede anything to the prejudices of a very powerful party opposed to it, why then, as medical men, should we yield to any heresy, however respectable or numerous its supporters? He was far from impugning the motives of Dr. Post when he offered the original resolution; that gentleman's views were well known. He simply contended that the record of the Academy should be clear and not open to misinterpretation.

Dr. Van Kleek took the view that Dr. Post's original resolution was not meant to cover every vote, debate and action of the Board, but had reference to general hygienic measures only. He thought that the matter was well enough understood, and that all of this hubbub was unnecessary.

The supplementary resolution was then passed, and copies of the same were, on motion of Dr. Sayre, directed to be sent to Drs. Parker and Stone, Commissioners of the Metropolitan Health Board.

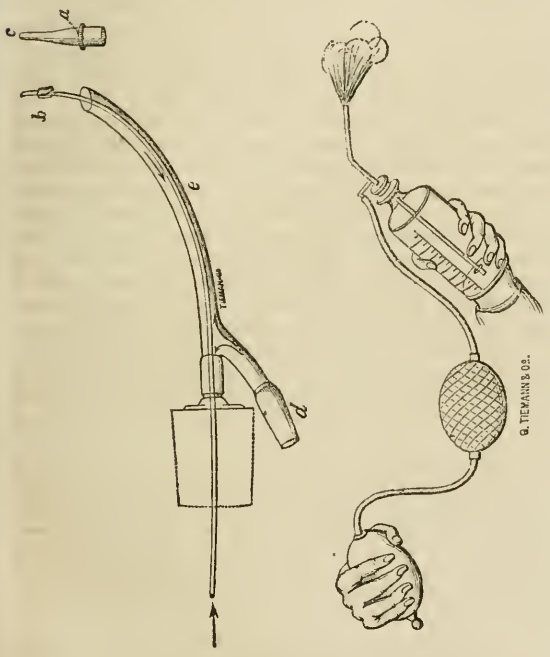
The Academy then adjourned.

New Instruments.

NEW INSTRUMENTS.

THE NEBULIZER OF DR. W. B. RICHARDSON, OF LONDON.

THE instrument of Dr. Richardson, of London, has now become so celebrated that every one has a desire to know all that is possible concerning it. We have heard enough of what it can accomplish, and what it may yet be able to do; but a great many are in ignorance of the principle upon which it works. It is not to be confounded with the ordinary Nebulizer, such for instance as those described in previous numbers of the RECORD, but it has a construction that is peculiar to itself, by virtue of which it has advantages over all others. It may be described as consisting in the first



place of a hollow curved tube, *e*, made of German silver, one extremity of which has an adjustable conical cap (*a*) while the other passes down into the bottle through a perforation in the cork. A short distance above the cork this tube has another, which is a short one (*d*), joined to it at right angles, and which is attached to the India-rubber tubing. Within the tube (*e*) there is contained a capillary one, which extends from within a line or two of the extremity of the cap, nearly to the bottom of the bottle, and beyond the bottled extremity of the larger tube. Near its upper extremity this capillary tube perforates a cylinder of metal (*b*) which almost completely occupies the calibre of the larger tube, and would entirely plug it up except that it has longitudinal grooves upon its surface.

The tubing and air balls are made of the finest rubber, are very elastic and very durable. The hand ball has, above and below it in the tubing, valves, the uses of which are sufficiently obvious. The netted ball in the centre of the tubing has very thin walls, and the mere pressure of the air from behind is sufficient to distend it. The netting is for the purpose of preventing an undue extension of the ball. Having now given a description of the parts of this beautiful instrument, we will proceed to illustrate its mode of action. We will start with the handball. This, by pressure, forces the air through the netted ball, and so to the cavity of the curved tube, *e*. One column of this air passes upwards through the tube, and the other downwards, as represented in the direction of the arrows in the figure. The upward column passes through the grooves in the circumference of the plug (*b*) into the cavity of the cap (*a*), and escapes through the capillary orifice (*c*) at its tip. This column of air passing over the extremity of the capillary tube, creates a vacuum in it, which vacuum is supplied by the fluid contents of the bottle. If the action should stop here we would have the merest drop at the extremity of the capillary tube. The next action is the division of the drops into spray. This is done by a continued current of the upper column of air passing in the manner already described. But this column of air being disproportionately large compared with the aperture of the tube, becomes compressed, and exerts a pressure upon the upper surface of the fluid in the bottle, which fluid is by it forced into the capillary tube. Thus we have a double force acting to produce a strong current of fluid through the capillary tube; first the production of a vacuum, and second, the pressure upon the surface of the fluid in the bottle.

It is this compression of the air, which, extending into the tube, serves to keep the netted ball more or less distended. The force with which this spray can be thrown is surprising. The jet, too, is comparatively steady, there being a pretty uniform pressure kept up by the regulating power of the netted bag, which by virtue of its elasticity compresses the air in it during the intervals of pressure upon the hand bulb.

The tube can be lengthened or shaped as desired, and the cap (*a*) may have two or three orifices.

Messrs. Tiemann & Co. have thought best to construct the tubes of pure silver. This, of course, makes the instrument more expensive; but the objection is counterbalanced by its greater utility and wider range of application.

Care is required in the manufacture of these instruments to get the required distance, between the end of the capillary tube and the orifice of the cap; for if the space be too great, the upper column of air regurgitates through the capillary tube, and instead of atomizing the drop, merely bubbles up through the water in the vessel.

For the purpose of producing local anæsthesia, we believe that there is no question but that this instrument supersedes all other nebulizers.

SANITARY CONDITION OF MEXICO CITY.—The following extract from a *New York Herald* correspondent's letter dated April 29th, gives a graphic but by no means flattering account of the sanitary, condition of Mexico city:

"All the filth from cesspools, sewers, and streets, and offal of every description, are deposited within the city walls, and within a few minutes' walk of the main plaza. The stench arising from this accumulation of putrid matter is carried over the city by every breeze, poisoning every breath inhaled; and in addition to this, the sewers through the principal streets are being opened, and the contents of thousands of vaults have been thrown out, their reeking fumes almost breeding pestilence in every quarter. These are matters which could be easily remedied, and would be elsewhere; but in Mexico the public health is never considered."

Correspondence.

LETTER FROM DR. STORER, OF BOSTON.

To the Editor of the Medical Record.

Sir—I find that an allusion made by me in a paper upon Excision of the Umbilicus, lately published in your journal, has given rise to much comment. I refer to my criticism of the vivisection at Boston, several years ago, of a condemned criminal, and of Dr. Calvin Ellis's association therewith.

Immediately upon the appearance of the paper, I became aware that I had touched a loud and long resounding string. Believing that the case in its scientific aspects was a very important one, I was not surprised at the interest immediately evinced in it by those who had never heard of, or had forgotten it. I was astonished, however, in view of my published disclaimer of any personal feeling, that my remarks upon the case should have been considered by any one as a personal attack upon Dr. Ellis, for whom, both as a physician and a gentleman, I have ever had the most profound respect, and whose friendship I have always valued. Finding that my motives were misunderstood by some, or perversely misstated, I endeavored, as soon as might be, to correct the matter, and in case I had really committed an error, to make, as I am always ready to do under such circumstances, the *amende honorable*. It was asserted, both privately and publicly, that I had violated all rules of medical criticism, had misrepresented the facts in the case, and had evinced gross ignorance of the simplest physiological principles. I hardly saw matters in this light, but nevertheless set myself earnestly and soberly to repair any wrong that I might have committed.

It will be recollected that I had expressed my belief that a supposed hanged person was alive at the time his autopsy was commenced. I had requested yourself to publish any scientific reply to my paper that might be sent you. I now offered to state in your pages that there existed doubts in some minds as to the relevance of my citation, the propriety of my exhuming a fact, even though very important in its scientific aspects and legal relations, that on some accounts had better have remained buried in the past, and even the correctness of my physiology, and I offered, moreover, to refer this latter point to the decision of any competent and impartial authority, say to Dr. Brown-Séquard. These offers, however, were declined, and I was told that nothing could suffice save the recantation of my abstract scientific opinion, which, of course, being unconvinced of error, I could not give.

Meanwhile, and during my absence at Baltimore as delegate to the American Medical Association, the affair was brought before one of our medical societies, the Suffolk district, isolated extracts were read from my paper in the Record, and a committee appointed to investigate them. At the first meeting of the Society after my return, I stigmatized this unusual procedure as, under the circumstances, alike uncourteous and improper, for it had received charges, by implication if not direct, against a member, and had undertaken to pass upon them during his absence; the matter in question, my paper in the Record, being one with which, as a society, it had no concern. I therefore simply denied its authority, ignored its committee, refused, as circumstances then were, to give any explanation whatever, and demanded that such action should be taken as justice to myself required. A special meeting of the society was accordingly held, at which the committee appointed for investigation reported that no charges had been made, and that they should render no report. The attempt at pressure thus being withdrawn, I read the entire paper from the Record, and volunteered the explanation that I could not have been forced into making; asserting, however, that my opinion of the vivisection was still unchanged.

Inasmuch as, during the discussion that ensued, the charge of ignorance of physiology in reference to this special topic was distinctly and deliberately repeated by the gentlemen who had previously preferred it against me, the editors of the Boston *Medical and Surgical Journal*, I am compelled to prolong this controversy. For myself, I can only say that I am forced into it against my will, having no leisure just now for such matters, and being anxious to do what I can to restore and to preserve professional harmony. I shall beg you to assist me in keeping the discussion, based as it clearly is, so far as I am concerned, upon difference of opinion as to a scientific point, free from all personalities whatever.

I have one word more to say. I regret that I have wounded the feelings of Dr Ellis, or have seemed in any way to bring discredit upon him. I was conscious of no unkindness of motive, and aimed at no personal attack; for these, I trust, are the prerogatives of smaller men. I considered my allusion a proper one; for the official papers that I cited were published, and are therefore the property of the profession, alike for reference and for criticism. I considered it a relevant one, for the gentleman had stated that he considered exploratory sections unwarrantable; he had ventured to sit in judgment upon my own, and it seemed fair to test his decision by his own previous practice. I thought, moreover, that my language, though strong, was yet not inappropriate. I had been told that my operation was unjustifiable. Successful, though it had been as an operation, the woman had died; if it were unjustifiable, I had therefore "incised my patient to death."

Viewing the matter, however, in the light that some have done, I see that the cases, though analogous, were yet not identical; Dr. Ellis having undoubtedly supposed his subject dead, while I knew that mine was alive, and meant to keep her so if I could, performing the section at her own request. I therefore regret sincerely that I applied the remarks that I did to Dr. Ellis.

I trust that I have now made all the reparation that can be demanded of another by any honorable man.

I may state, moreover, that had I possessed at the time of writing my article evidence now in my possession, I should never have held Dr. Ellis to any responsibility in the case, and that I now consider him as fully relieved from such. The burden of the whole matter rests with Dr. Henry G. Clark, at that time city physician of Boston, by whose order the vivisection was made, and whose business it was, if any one's, to ascertain and to decide if the man was really dead. Dr. Clark having avowed himself solely responsible, in a pamphlet of whose existence I was ignorant until since my article was written, and having now again declared that the affair is wholly his own, I regret anew that I should have wronged Dr. Ellis by putting him in the position which justly belongs to Dr. Clark.

The *London Lancet*, whose editorial I had forgotten till just now reminded of it, years ago saw this case in its true light.

Its avowal of it was at that time denounced as malignant, and an evidence of extreme ignorance of physiology. It may yet prove that such charges as the

last recoil upon their makers, however high their position, or the reverence their dicta have hitherto received.

In another communication, and as a contribution to medical jurisprudence, I may take occasion to discuss the questions: 1st, as to whether it is proper, advisable, or necessary, to ascertain whether criminals are alive or not at the time of their dissection; 2d, as to what constitutes in such cases probable, and what decisive, evidence of the persistence of life; and 3d, as to whether medical men, if careless or ignorant of physiology, may become *criminally* responsible to the laws of the land. The profession shall then decide as to which of the parties in this controversy—for it will be found to include more than originally entered it—are sound in their physiology, and which have contributed to, or desired to interfere with, the advancement of their science.

Yours sincerely,

HORATIO R. STORER, M.D.

HOTEL PELHAM, BOSTON, June 8, 1866.

PROF. SIMON, AND THE RESULTS OF OPERATIONS FOR VESICO-VAGINAL FISTULÆ.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR—Under the heading of "Progress of Medical Science," in the issue of June 15th of your Journal, an extract from the *Hanover Zeitschrift für pratische Heilkunde* is given, which, from claiming so much for the practice of Prof. Simon in the hospital at Rostock, should not, in justice to American surgery, be passed unnoticed.

"Simon has, up to this time, operated on about seventy vesico-vaginal fistulæ, a number which before and contemporaneous with him, no operator has reached, and has attained results which by far exceed those of the Frenchman Jobert, and the American Sims. Of forty-three fistulæ occurring in forty women operated upon by Simon, up to 1862, and published, thirty-five were perfectly cured, five almost perfectly, only one remained unrelieved, and two died. The result of the last two and a half years, which comprehends more than thirty operations for fistula, and which will soon be published, shows a much more favorable experience; so that of all those operated upon, which now amount to more than seventy, only two remain unrelieved, while two have died.

"It is not too much to say that Simon restores continence of urine in every defect of the vesico-vaginal wall, including the defects of the uterus and of the recto-vaginal wall, when only a piece of healthy urethra remains, which is from two and a half to three centimètres long."

To the ingenuity of Dr. J. Marion Sims, we owe nearly everything in the success of this operation; and as a result of his teaching there are comparatively few surgeons in the country who have not operated successfully. Dr. Sims, previous to his departure for Europe, in private practice and service as Surgeon to the Woman's Hospital, had operated successfully in nearly two hundred cases, and during the past five years I have had about the same number. The result of my hospital service and private practice during the past year alone has been fifty-seven cases of vesico and recto-vaginal fistulæ *cured*.

Having been connected with the Woman's Hospital since its foundation, eleven years ago, and familiar with Dr. Sims's private practice previous to his leaving the country, I can state (and the same for my own service) that not a single death has ever occurred from an operation for fistula, or from any preparatory operation.

It must be claimed for this country, that with the aid of plastic surgery, scarcely a case is incurable, and a favorable result is only a question of time and perseverance.

Many members of the profession, during the past three years, have witnessed at the Woman's Hospital the various steps of successfully restoring the urethra by means of plastic surgery, in cases where it had been entirely lost. A short time ago a case was discharged from the hospital cured, after having been an inmate some three years, and having had twenty progressive operations for her relief. She was admitted with an entire loss by sloughing of the vesico-vaginal septum, the urethra, and all the tissue under the arch of the pubes, the cervix uteri, and cul-de-sac.

The vagina was not more than an inch and a half deep, and so contracted at its outlet by cicatricial tissue as to barely admit the index finger. When discharged, a urethra had been formed by flaps from the neighboring tissue, the uterus retroverted, drawn down and united to it, so as to form the base of the bladder, and by dividing the cicatricial tissue and opening up the lost cul-de-sac, a vagina some five inches deep was permanently gained. Although the bladder could not be emptied except by means of a catheter, the urine could be retained without inconvenience for twelve hours at a time.

The progress of this case is familiar to a very large number of the profession, and it must be regarded as a remarkable triumph of surgery, as it would be almost impossible for a greater destruction of the parts to occur.

A greater success in this operation must be claimed for this country than elsewhere, from the fact that the number furnished from the western and thinly settled portions of the country is so great from a want of proper medical aid, that the average destruction of the soft parts is greater than could ever occur in the thickly settled countries of Europe.

THOS. ADDIS EMMET, M.D.,
Surgeon to the Woman's Hospital.

June 18, 1866.

QUARANTINE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR—I voted with the majority of the members of the American Medical Association on the subject of recommending to Congress to test the utility of the quarantine measures proposed by Dr. Marsden of Quebec. In the notice which you took of the action of the Association, in the RECORD of May 15th, I think that a little reflection will satisfy you that there was some departure from the spirit of courtesy and impartiality which is so striking a characteristic of the editorials which usually proceed from your accomplished pen. As a representative of the majority of the association, I feel that an apology is due for certain expressions contained in the notice to which I am alluding. At the same time I desire to defend myself and those with whom I acted from the implied charge, either that we acted without an enlightened and comprehensive view of the subject which was before us, or, what is still worse, that our course was directed by a partisan spirit, andthat it was in disregard of the great interest of public health.

Now, I do not claim that those who voted with the majority were certainly right, and those who constitute the minority were certainly wrong. I admit that there was room for an honest difference of opinion, and that neither party has a right to impugn the motives of the other, or to bring forward an accusation either of moral obliquity or of mental inferi-

ority. It is not fair to set down all who voted against the reference of this subject to Congress as absolute non-contagionists. I have no doubt that we represented a variety of shades of opinion on the subject of contagion. But, at the same time, I suppose that we were pretty generally agreed as to the impossibility of excluding the pestilence by any quarantine regulations which might be adopted by the Government. We live in the midst of a great commercial community, having extended relations with every part of our country, and with foreign lands. If, in time of war, the utmost vigilance of a blockading squadron is insufficient to prevent vessels from entering the harbor which they are guarding, how is it possible, in time of peace, to prevent persons or goods from being landed at any point on our widely extended coast? But the question may be asked, what harm there would be in making the attempt, even if in the end it should prove to be unsuccessful. I will endeavor to answer this question, and I hope to be able to do so in such a manner as to convince gainsayers that the opponents of a rigid quarantine are not necessarily acting in a spirit of blind partisanship, or in disregard of the great interests of the public health.

The evils which are necessarily attendant upon a rigid personal quarantine are of such appalling magnitude, that nothing could justify the system, unless it can be shown to possess an undoubted efficacy in preserving the community from pestilential diseases. A personal quarantine subjects the unfortunate passengers on board of a ship, or the inhabitants of a town where a pestilential disease has broken out, to a privation of their personal liberty, often attended with extreme hardships to themselves, and to those who are dependent on them. It often compels them to remain for a long time in a situation where they are exposed to morbific agencies, by which they are brought into great peril, and by which their lives are frequently sacrificed. This evil is of such magnitude that I am inclined to the opinion that personal quarantine has been the means of destroying more lives than it has saved.

As an instance of the deadly effects of a rigidly enforced personal quarantine, it may not be out of place to allude to the merciless confinement of steerage passengers now going on in our harbor. When I read the daily record of the deaths of Scandinavian and German men, women, and children, offered as sacrifices on the altar of what I regard as a narrow-minded theory, I can scarcely repress the indignation which I feel with reference to a system so unworthy of an enlightened community in the nineteenth century.

The system of personal quarantine inflicts incalculable injury upon commercial cities to which it is rigidly applied, deranging the ordinary operations of commerce, and subjecting to great loss those who are engaged in them. It may be said in reply, that human life is incomparably more precious than commercial gains and material wealth. But if the business of an important commercial city is greatly deranged, many of its inhabitants will be thrown out of employment; they and their families will be subjected to severe privations, and will consequently become the ready victims of such diseases as ordinarily prevail in the community. And if, in spite of the rigid execution of the quarantine laws, the pestilential disease, which they were designed to exclude, should be introduced through some unguarded entrance, and should obtain a foothold in such a community, would not the ravages of the pestilence be fearfully increased by the very means which had been designed to guard against its entrance? I am not drawing a fancy picture. The records of the dreadful plagues which desolated Europe during the middle ages bear witness to the importance of the warning which I have given. Among the scenes of horror, almost defying the power of human description, the dreaded quarantines and sanitary cordons played a most conspicuous part, adding to the terrors of the pestilence, and greatly multiplying its victims.

A rigid personal quarantine acts injuriously upon the public health, by pandering to the popular prejudice which regards personal communication with the sick as being the principal means of spreading pestilential diseases, and by diverting the minds of the community from the more important sanitary measures by which the public health may be promoted, and the ravages of the pestilence may be more certainly limited. The impression thus made upon the popular mind, often leads to the inhuman abandonment or neglect of the sick, leading to a fatal result in many instances, where humane treatment and good nursing might have been followed by restoration to full health.

And persons relying on the protective power of quarantine may be led to neglect those habits of personal and domestic cleanliness, and of obedience to the known laws of hygiene, by which they may most effectually secure themselves against the ravages of disease.

My attention has recently been drawn to a statement in the New York *Daily Times*, that the cholera attacked a family living in a filthy neighborhood called Dutch Lane, in the outskirts of Elizabeth, in New Jersey. And the startling announcement was made that the inhabitants of the town held a meeting, and determined to arrest the disease by drawing around the devoted district a sanitary cordon, and rigidly excluding ingress and egress. Can it be believed that such a barbarous and inhuman practice could have been countenanced among the inhabitants of a Christian town in the nineteenth century? And if in consequence of an act so monstrous and cruel, the citizens of Elizabeth should experience the full power of the destructive pestilence, would there not be great force in the question: Those scores on whom the pestilence in Elizabeth "fell, and slew them, think ye that they were sinners above all men that dwelt in the land?"

Would it not have been more worthy of the inhabitants of an enlightened Christian community, instead of shutting up the unfortunate dwellings in Dutch Lane, in their filthy and insalubrious quarters, if they had extended to them the hand of friendly sympathy, if they had assisted them in cleansing and disinfecting their dwellings, and if they had aided and encouraged them in escaping to a more healthy locality?

In conclusion, I would express the hope that the members of our profession may profit by the experience of past ages, and may cultivate such enlarged and liberal views of this whole subject as will prevent them from going back to the exploded theories and practices of the dark ages, and from encouraging our civil authorities to inflict upon the community the terrible quarantines and sanitary cordons under which our ancestors groaned in bygone centuries.

Yours respectfully,

ALFRED C. POST, M D.

THE "CHOLERA CAMPAIGN" AGAIN.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR—In your issue of June 15, 1866, I observe an article from the pen of Harvey E. Brown, Assistant-Surgeon U. S. A., upon the subject of the cholera on board the steamer *Henry Clay* loaded with U. S. troops in 1832. He states that the "expedition was broken up near Fort Gratiot." So indeed it was as to the troops on board the *Henry Clay*.

As I participated largely in the subsequent events of that campaign, it seems proper for me to continue the interesting history which Dr. Brown has commenced. Besides the *Henry Clay*, another steamer, the *Sheldon Thompson*, had preceded it, on board of which was Major-General Scott and his staff and several hundred U. S. soldiers bound for Chicago, and thence by land to Rock Island, in the Mississippi river. The *Sheldon Thompson* arrived at Chicago late at night in July (date not recollected). Soon after passing Fort Gratiot, cholera broke out on that steamer and many dead bodies were thrown into the lake, and on reaching Chicago the deck was covered with the sick. As there was no hospital at Fort Dearborn (Chicago), by my advice the two companies of U. S. troops were moved into tents one mile from the fort, and all the rooms were prepared for the reception of the sick from the steamer, and forty cases were brought to it the next morning soon after sunrise. Other vessels soon after arrived with troops from Fort Brady, Sault St. Marie, and, I believe, from Fort Howard, Green Bay, with cholera cases. The military posts from which they came were healthy, nor had the people there heard that cholera was in the country, as I was informed. Here appears a fact seemingly corroborative of the opinion expressed by the officer whom Dr. Brown quotes. The vessels spoken of above struck the track of the *Sheldon Thompson* at the head of Lake Michigan and followed it to Fort Dearborn (Chicago), about two hundred miles; and it is reasonable to suppose they passed all that distance in a cholera atmosphere. I could say much more in connexion with this cholera campaign, as I had the entire charge of the sick after their arrival at Chicago, but my only object in writing this article is to state facts which seem to sustain the views of Dr. Brown as to the way cholera is propagated.

Very respectfully,

S. G. J. De Camp,

Surgeon, U. S. Army.

Saratoga Springs, N. Y., July, 1866.

Medical News.

Personal.

Dr. Joel Morse, Surgeon of the 117th U. S. Colored Infantry, in charge of the Post Hospital, at Brownsville, Texas, was waylaid near the government corral, below that city, by the Mexicans, who lassoed him, dragged him into the chapparal, and there murdered him. This occurred May 27.

Dr. A. W. Webb and his son were murdered in bed, at Little Rock, Ark, on the 14th ult., for the sake of the plunder in the house.

Dr. Daniel Brainard and family, Chicago, and Dr. E. R. Hun, Albany, N. Y., according to latest advices, are at present in Paris.

Dr. J. H. Douglass has resigned as editor of the New York Medical Journal.

Surgeon John E. Summers, United States Army Medical-Director, and Brevet Major William L. Porter, are announced as the staff of the Major-General Commanding Department of the Cumberland.

Surgeon E. S. Bogert has been ordered to duty at the Naval Hospital at Norfolk, Va., *vice* Passed Assistant-Surgeon J. B. Ackley, ordered to the *Madawaska*. Surgeon Henry C. Nelson, from the receiving-ship *New Hampshire*, and waiting orders. Assistant-Surgeon William J. Simon, from the storeship *New Hampshire*, and waiting orders. Surgeon William Lowber and Acting Assistant-Surgeon E. D. Martin, from the receiving-ship *Princeton*, and ordered to the receiving-ship *Constellation*. Passed Assistant-Surgeon D. McMultrie, from the receiving-ship *Vermont*, and ordered to the steamer *Macedonian*. Surgeon J. J. Gibson, from the receiving-ship *Constellation*, and ordered to the receiving-ship *New Hampshire*. Acting Assistant-Surgeon George L. Simpson, detached from the steamer *Chicopee*, and ordered to the coast-survey steamer *Bibb*. Acting Assistant-Surgeon A. C. Fowler, from the coast-survey steamer *Bibb*, and ordered to the steamer *Chicopee*.

Henry James Anderson, M.D., LL.D., class of 1818, has been reëlected President of the Alumni Association, Columbia College, New York.

Henry Darwin Rogers, LL.D., F.R.S., &c., Professor of Natural History in the University of Glasgow, died on the 29th of May, at his residence, Elgin Villa, Shawlands. Professor Rogers was one of the most distinguished of American savants, and the only one who has received the compliment of a foreign chair.

Progress of the Cholera.

Liverpool, Eng.—Cholera has reappeared in one of the worst districts of Liverpool.

Prussia and vicinity.—It has also broken out at Stettin, near the mouth of the Oder, in Northern Prussia. This is but a step from Berlin, whence it may pass to the armies on the frontiers of Saxony and Bohemia.

Elizabeth, N. J.—The disease manifested itself fatally in this city on the 19th ult. The facts are substantially as follows: C. B., a pot-baker, in the employ of the Metropolitan Gas Company, of Elizabeth, moved from a mere shanty, situated among the flats, the cellar of which was ever filled with stagnant water, into a three-story tenement-house, placed on low grounds, with stagnant pools completely encircling it. Under this one roof no less than six families dwelt, in all 30 souls. C. B. was a man of intemperate habits, as was also his wife. To such an extent of poverty had his evil habits brought him, that he died without the common necessaries of life.

Sunday, C. B. passed away in the lager-beer saloons and rum-shops that infest his neighborhood, in company with another, who has since been taken down with the same disease.

On Monday morning he did not feel well enough to go to work, and mentioned to the neighbors that he felt the effect of the beer he had drunk. At 10 A. M. he was attacked with symptoms of cholera, and a physician was summoned. Vomiting, cramps, and purging ensued, together with copious "rice-water discharges;" and at 9 A. M., on Tuesday, he expired in convulsions.

A daughter, aged eleven, died at 11 P. M. of the same day, and on the 20th the wife was attacked. Immediately afterwards a well-to-do German living in Dutch Lane, one hundred feet distant, was seized with the disease, and died at 2 A. M. of the next day. While the last-mentioned person was sick, a dock laborer residing some two doors north was stricken, and also died after an illness of a few hours in duration. A medical commission, appointed by the Governor of New Jersey, have pronounced the cases as cholera. Another version of the origin of the disease is as follows: A person from a Quarantine ship, after remaining in Elizabeth for a few days, was seized with choleraic symptoms, and the infection, it is claimed, was traceable to the water-closets which he visited. The Mayor of the city, himself a physician, writes a public letter under date of June

27th, to the following effect:—"The reports in regard to cholera at Elizabeth, N. J., have been greatly exaggerated. We have had a few cases in a low, filthy, and sparsely populated locality; but at this time there are no cases, nor have there been any for the last three days. The citizens of the affected district have been relieved from all restrictions, it having been thoroughly cleansed and disinfected, and the disease having entirely disappeared."

Quarantine, N. Y.—It is a remarkable fact, that since the separation of the German and Irish emigrants on board the steamer Union—a period of over twenty-two days—there has not been a single case of cholera on board that vessel The whole number, 173, were accordingly sent to this city on the 3d inst. We have, at the time of writing, the gratifying assurance that those now detained in the hospital-ships are suffering from the resulting debility merely.

New York City.—Cases of cholera are occasionally reported, but the number in comparison with the population is exceedingly slight; or, to quote the language of Dr. Harris, the disease "has scarcely found foothold in the city." "The exotic pestilence, which has in well known localities suddenly destroyed a few lives," says Dr. H., in the same report, "seems to have been wholly subdued in every block where it has appeared." As an indication of the view entertained of the public health by authorities abroad, we may barely refer to the fact that the Captain-General of Jamaica, under date of June 6, virtually declares New York an infected port. He requires all vessels leaving the harbor to bring with them bills of health, countersigned by Her Majesty's Consul. Without these no landing of passengers or discharge of cargoes will be allowed.

At the commencement of the New York University, June 21, the following among other degrees were conferred:

Master of Arts.—Charles H. Ludlam, M.D., James Brown Burnet, M.D., Cornelius Van Riper, M.D, of class of '63.

Doctor in Philosophy.—J. Ghislani Durant, M.D., New York.

Doctor of Medicine.—Alex. W. Stein, N. Y.; Edwin A. Knight, N. H.; D. B. T. McBean, C. E.; Oscar T. Sherman, N. Y.; Charles M. Stanley, N. H.; R. Perez Martinez, West Indes; Emilio A. Sanson, West Indies; J. W. McAfee, Oregon; Jirges Churu Kyan, of Latakia, Syria; Nerses Kulugian, of Marash, Turkey; Kerock Guluzyan, of Marash, Turkey.

A New Asylum for the Insane.—The subject of a "Hudson River Asylum for the Insane," provided for by the last session of the Legislature, is being considerably agitated by prominent residents of the various cities and towns along the Hudson. The Governor has appointed the following-named gentlemen as commissioners, for the purpose of selecting a suitable site for the erection of the edifice, which is to cost half a million of dollars: A. W. Palmer, Amenia, N. Y.; Wm. S. Kenyon, Kingston, N. Y.; John Falconer, New York City; Dr. J. M. Cleaveland, Utica, N. Y.; and Joseph B. Taylor, New York City. It is barely probable that the building will be erected on grounds situated a short distance from this city, although Hudson, forty miles north, is also looked upon with favor by the commissioners. The Chairman of the Commissioners being the originator of the bill, and he being a resident of the county of Dutchess, are facts that will have their influence towards the selection of grounds near Poughkeepsie.

Marine Hospitals.—A bill providing for the sale of marine hospitals in which only twenty patients per diem are received, has passed the U. S. Senate.

The Almshouse — Department of Infants.—The Commissioners of Charities and Correction at their semi-monthly meeting, June 14, created a new department of the Almshouse, with the above title, which is to be under the Warden's superintendence, and will be for the benefit of infants under two years of age.

Fees for Attending Clinical Lectures at the Bellevue and Charity Hospitals.—The sum of three dollars has been fixed upon by the Commissioners of Charities and Correction, as the fee for attendance upon the clinical lectures of the Bellevue and Charity Hospitals.

Long Island Hospital College.—The commencement exercises of this college were held at the Athenæum, Brooklyn, on Thursday, the 28th ult. There were forty-six graduates.

Circular No. 6.—Surgeon-General Barnes has published in circular form for distribution, extracts from letters received by him from the leading surgeons in the world, bestowing the highest possible encomiums on his circular No. 6, and expressing the hope that our government will provide for the publication of a volume embodying the experience of the medical staff during the war.

A Sensible Ship's Captain.—The following, as rather significant in a sanitary point of view, we clip from the *Herald* of the 15th ult:

"The ship Antarctic, Captain McStoger, arrived at this port on the 11th instant, in thirty-three days from Liverpool, with five hundred and seventy-one steerage passengers, all in good health. One-fifth of her passengers were Germans, a similar class of people to those who had recently arrived infected with cholera, yet still not a single case of contagious disease broke out among the Antarctic's passengers; for the captain made it a rule, to be rigidly observed by all on board, that, so soon as he left Liverpool, all the passengers should be on deck at least once a day, the weather permitting; and that the between-decks should be swept perfectly clean and thoroughly scrubbed and washed down, and when dry an abundance of chloride of lime should be sprinkled around and under all the berths, as also other disinfectants should be used. Besides all these precautionary measures the captain adopted a plan peculiarly his own—not the old system of sprinkling it here and there about the ship, but he had the boxes disadjusted from the pumps and the disinfecting fluid poured down into the ship's bilge, and allowed it to remain there for the space of twenty-four hours. After that it was pumped out, which imparted to the ship a good and wholesome smell, and effectually destroyed the miasma usually arising from bilge-water, which is the great evil with which all ships have to contend, and which, in nine cases out of ten, is the principal cause of sickness on board ship, especially emigrant vessels which are not properly ventilated."

Errata.—Page 210, second column, twenty-eighth line from the bottom, read "the disease was *not* considered epidemic." Page 211, thirty-first line from top, instead of "two or three days," read "two to six days."

On page 214, second column, fourth line from the bottom of Dr. Dyer's remarks, for *placid* read *flaccid*. On page 215, first column, thirteenth line from the bottom of the page, read *Dr. C. Schweigger* instead of *Schreigge*.

Original Communications.

TRICHINIASIS, WITH CASES.

By H. RISTINE, M.D.,

OF MARION, IOWA.

This disease, which has prevailed so extensively in Germany during the last few years, and some isolated examples of which have been reported in the United States, has recently made its appearance in this vicinity; and from its novelty, the striking features which it presents, and the fatality with which it has been attended, has excited great interest with the medical profession throughout the country.

The circumstances connected with the advent of this hitherto unknown disease were somewhat peculiar. Two families, one living in town, the other at some distance in the country, and having no communication with each other, were each visited at nearly the same time with a disease characterized by symptoms of a very similar and, in some respects, unusual character. The first consisted of an old gentleman named Bemis, his wife, and two sons, Henry and Whitfield, and a son-in-law named Lansing, with his wife and four children: in all, ten persons. All of these, with the exception of Mr. Lansing, were taken sick about the fifth of May with symptoms resembling in some degree those of typhoid fever, for which the disease was at first mistaken, by the physician in attendance, Dr. E. M. Smith. On the 31st of May I was called in consultation, in connexion with Dr. Bardwell; and after a careful examination of the symptoms, which had by this time become fully developed, and their antecedent history, the disease was diagnosticated trichiniasis.

The symptoms varied somewhat in the different individuals, but they bore a sufficiently close resemblance to each other to justify the belief that they all proceeded from the same specific cause. William and Albert Lansing, aged 13 and 5 years respectively, were the first ones in whom the symptoms were observed. They consisted at the outset of diarrhœa, attended with more or less abdominal pain, and accompanied by a much greater degree of prostration than usually attends ordinary diarrhœa. They soon began to complain of muscular pains, and a general feeling of soreness and stiffness, followed by considerable febrile disturbance; œdema of the face and ankles; diaphoresis; furred tongue; itching at the nose; nausea; and thirst. In two or three days after the supervention of these secondary symptoms, the diarrhœa and œdema of the face subsided; the other symptoms became aggravated. The increasing soreness of the muscles rendered movements of the limbs difficult and painful; the tongue became dry and brown, with a well defined red border; pulse weak and increased in frequency; legs and thighs œdematous. Nausea marked the invasion of the disease, but the appetite has since been good. The temperature of the surface was not materially increased. Emaciation was extreme. The symptoms in both cases were much the same until the close of the second week, when the younger boy gave evidence of bronchial irritation, resembling the subacute bronchitis met with in protracted cases of typhoid fever.

The others were successively, and at very short intervals, attacked in the same manner. The same character of symptoms was present in the cases of Mrs. Bemis and Henry as in the two children, except that in the former the pulmonary organs were implicated from the commencement. During the third week the pulmonary symptoms increased in intensity, and presented all the characteristics of capillary bronchitis. They involved dull pain in side and breast; hacking cough, with a viscid muco-purulent and orange-colored expectoration; dyspnœa, which became exceedingly distressing when in a recumbent posture, and compelled the patient to maintain a semi-erect position; pulse from 100 to 120; respiration, 36 to 40; speech, jerking and interrupted; resonance on percussion normal; subcrepitant râle audible on both sides of the chest. No change was observed in the sounds of the heart. The bowels became tympanitic, and the urine scanty and high-colored. Indisposition to sleep and restlessness, and, in the case of Henry, mild and transient delirium, marked the progress of the disease.

The old man was in feeble health when the disease assailed him, and the symptoms in his case bore a closer resemblance to typhoid fever than in the others. No local derangements were manifested after the abatement of the diarrhœa. The tenderness of the muscles and prostration were so extreme as to render it impossible for him to change his position without assistance. The latter, indeed, almost amounted to paralysis, and was a marked feature from the outset. The pulse was weak and frequent; tongue dry, with a dark brown coating; abdomen contracted and tense; indeed, the intestines appeared to lie entirely on either side of the spinal column, and the pulsations of the aorta and common iliacs could be readily distinguished through the abdominal walls. Emaciation in his case seemed more marked if possible than in the others; the muscles of the extremities were exceedingly soft and flabby, and seemed to be almost entirely devoid of consistence. The other cases involved the same general symptoms as in those narrated above, but in a milder form.

Upon these symptoms, taken in connexion with the statements of the family, the diagnosis was based. On being interrogated, they stated that about three days prior to the first development of the primary symptoms, and continuing during a period of five or six days, they had all, with the single exception of Mr. Lansing, partaken more or less freely of uncooked ham, which was served upon the table in that condition. Mr. Lansing, who alone remained unaffected, was away at the time, and did not eat any of the raw meat; but he, on his return, eat freely of the same ham after it had been thoroughly boiled, his wife having made this disposition of the remainder. She eat a portion of it in a rare or underdone condition, but eat none of it raw; and although she had suffered severely in the same manner as the rest, was already convalescent. Henry Bemis, who appeared to be in the most critical condition, acknowledged that he had frequently gone to the cupboard between meals and eaten slices of the same meat. The relation of cause to effect was thus so clearly established that the character of the disease could not be mistaken; though, as the meat had all been consumed, we were unable to demonstrate it. All doubts nevertheless which could have arisen were very effectually set at rest soon after by the aid of the microscope. The day after the consultation, while the propriety of "harpooning" a portion of muscle was being discussed, the older of the children died; and upon examination, the muscles were found to be alive with trichinæ, most of them being free and a few encysted. A friend, who is a competent observer, counted one hundred and four trichinæ in a piece of the rectus femoris measuring one-twelfth inch square by one-twelfth inch thick, which would give nearly 180,000 to the cubic inch. Specimens of the muscle were sent to Professor Flint, Jr., New York; Professor Ingals, Chicago; Dr. Horr, Dubuque, and others, all of whom confirm the statement as to identity and numbers.

Objection on the part of the mother of the child precluded a critical examination of the thoracic and abdominal viscera; but no lesion could be discovered by inspection, except that the transverse and descending colon appeared discolored. Four others of the number have since died; but the unwarrantable prejudices on the part of the family have prevented our making examinations *post-mortem*, except in the case of the old gentleman, who died June 15th. As death in his case was purely from asthænia, with no noticeable functional derangements, we did not expect to find much of pathological interest in the examination of the viscera. The only lesions discoverable were some peritoneal adhesions, with the same discoloration of the colon observed in the other case. Trichinæ were found in all the purely voluntary muscles, diaphragm, pectorales, spleen, lungs, etc. They were not observed either in the heart or liver.

Mrs. Lansing and her brother have almost entirely recovered; her two remaining children are convalescent, and there is little doubt of their early and complete recovery. The treatment adopted was mainly supporting and expectant, with the hope of prolonging life until the parasite should become quiescent and encysted.

The other cases alluded to are six in number, and are included in four families named Jordan, relatives, living in the same neighborhood, twelve miles from town. They were all children, with ages ranging from seven to seventeen years. They had been complaining since the 27th of April, but the symptoms were not of such an aggravated character as to excite apprehension. I saw them once previous to the discovery of the real nature of the disease, of the cases in town, and I attributed the symptoms to their having eaten something of a poisonous nature. This was about three weeks after the first manifestation of the symptoms, and all but two of the patients were able to be about; indeed they had not been confined to the bed at any time. The symptoms, in all, were very similar to those in town, though of a much milder type; but there was no pulmonary disturbance in any of them. I prescribed a hydragogue cathartic and some palliative measures; and directed the parents, in case the children did not improve, to send for me. As I heard nothing from them for some time, I paid no further attention to the matter.

Shortly after the disclosures made in the Bemis family, I was again called to see the Jordan cases; I found them all convalescent except the oldest girl, who had been improving until within a few days, when she began to cough. This was hacking and frequent, and attended with little expectoration; respiration moderately increased; pulse weak; on percussion resonance normal; respiratory murmur a little rough; with a slight subcrepitant râle on both sides. The patient was emaciated, the lower extremities œdematous, and the muscles still painful. I suspected the cause, and inquired whether the children had at any time eaten any raw bacon. At first they did not recollect having done so; but it was incidentally disclosed by a child of one of the neighbors that all the individuals affected had, on the 25th of April, congregated at one of the houses, and while there had eaten chips of raw meat from a ham which was lying cut upon the table in the kitchen. On the 27th they were most of them seized with diarrhœa, followed in two or three days more by the other characteristic symptoms. In the oldest girl the order of succession was reversed, the muscular pains preceding the diarrhœa.

It is a universal practice here with the country people, to combat every kind of disorder with an active cathartic; and the ever-ready dose of pills was accordingly administered to each of the ailing ones. This treatment, which is inculcated and carefully fostered by the patent-medicine venders through the medium of almanacs, happened, in this instance, to have been the only kind that could, as far as is at present known, have been of any avail. Every one of the children who took the purgative have recovered or are convalescing, after having experienced a regular succession of the symptoms of trichiniasis. The oldest girl, however, was in town throughout the following week; and, as she was in apparent good health on leaving home, did not take the cathartic. She is the only one who is now in any danger.

None of the ham of which they had eaten was left; but its counterpart, which had been put up in brine, was examined and found to contain trichina cysts in abundance, though I have yet been unable to determine whether the worms are living or not.

The opinion prevails very extensively in this vicinity, that the trichina spiralis exists in the flesh of hogs which have been affected with hog-cholera. The symptoms in the latter disease, as it has manifested itself here at various periods during the last three years, are, first, diarrhœa, followed by swelling of the neck, stiffness of the limbs, debility, muscular atrophy, and frequently cough; phenomena almost identical with those of trichiniasis.

The ham which produced the disease in the Bemis family was cured by a son of Mr. Bemis, residing near town. He had had some cholera among his hogs, but this one was not known to have been diseased; the other ham and one of the shoulders were eaten by his family, but always in a well cooked state. The other shoulder having become tainted, was thrown out, and devoured by a fine sow, a short time before the discovery of trichinæ in the ham. She was soon after taken sick, and died with all the symptoms of hog-cholera. On examination, her muscles were found to be infested with free trichinæ in great numbers. There had been a great deal of cholera among the hogs in the Jordan neighborhood, but none were packed which were known to have been diseased. In order to test the matter, during a recent visit of Dr. Horr of Dubuque, who came here for the special purpose of investigating the disease, and to whom I am indebted for some valuable suggestions, we excised a portion of muscle from the ham of a living hog, which was said to have been sick last fall with the cholera. We have not yet been able to discover the parasite, but we will not feel satisfied without a further investigation.

The following conclusions may, I think, be consistently deduced from the foregoing statements:

1. That symptoms indicating the presence of young trichinæ in the tissues were observed as early or earlier than the fourth day after the ingestion of the trichinous meat.

2. That cysts are formed as early as the twenty-fifth day.

3. That other things being equal, the severity of the symptoms is in direct proportion to the amount of trichinous meat eaten.

4. That an active cathartic given while the worms are still within the intestinal canal, is effectual to a certain degree in causing their expulsion, and mitigating the severity of the disease.

5. That youth affords no immunity from the effects of the disease.

6. That salting and smoking do not destroy the vitality of the parasite.

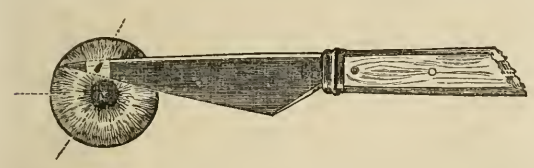
7. That thorough cooking accomplishes this object.

A METHOD FOR REMOVING A FOREIGN PARTICLE FROM THE CORNEA.

By C. R. AGNEW, M.D.,

OF NEW YORK.

A. B., a machinist, while "driving home" with a hammer and chisel the packing of a pump, detached a bit of iron, which entered and imbedded itself in his right cornea, a little below its centre. I saw him for the first time on the 22d of the present month,



one year after the occurrence of the accident. Immediately after the occurrence of the accident he sought advice, and had persistent but unsuccessful efforts made to remove the foreign particle. For twelve months the particle of iron lay in the cornea, keeping up a constant irritation. When the case came under my observation, I found that the particle of iron had perforated the cornea, tapped the aqueous chamber, and was resting with one end in the anterior chamber, and the other on a level with the external surface of the cornea. Iritis was rapidly coming on. I soon satisfied myself that any attempt to remove the particle of iron by simple manipulation from without would result in forcing it into the anterior chamber, and lead to loss of the eye by consecutive inflammation.

Accordingly I placed the patient under an anæsthetic, and proceeded to operate for the removal of the particle, as indicated in the diagram. I first held the eyelids apart by means of a spring, or wire speculum, then passed a Beer's knife through the cornea behind the foreign particle, and out again towards the nasal margin of the cornea, so as to present a retentive barrier behind the foreign particle.

An assistant now held the Beer's knife, while I gently dug out the particle from the depths of the corneal ulcer. A few drops of a solution of sulphate of atropine, two grains to the ounce of water, were now dropped upon the eye, and a light compress wet with cold water applied. In two days all traces of the incisions in the cornea had disappeared, and the small ulcer left by the removal of the foreign particle was kindly healing up.

The main points in the case are, that the foreign particle had penetrated and drained the anterior chamber; that it was lying in the corneal wound, and keeping up a violent irritation, threatening destructive inflammation; and so nicely balanced that the slightest effort made to remove it by manipulation from without would have tilted it into the anterior chamber, where it might have been lost, and thus have become the occasion of destructive irido-choroiditis.

The diagram shows the Beer's knife traversing the anterior chamber behind the foreign particle, which is lodged in an isthmus of cornea intervening between the incisions.

Tax Levy for Hospital Purposes in Mississippi.—General Fisk, of the Freedman's Bureau in Mississippi, has levied a *per caput* tax of one dollar upon the colored people under his jurisdiction, for hospital purposes, in the event of a choleraic visitation. Effective measures have been adopted to enforce the order.

NOTES ON THE TREATMENT OF STRICTURE OF THE URETHRA.

By WALTER TYRRELL,

LATE DEMONSTRATO ROF ANATOMY AT ST. THOMAS'S HOSPITAL, LONDON.

I am desirous of laying before the profession a few remarks on the treatment of stricture, which have occurred to me in the course of practice. In treatment of spasmodic stricture, I think that we do not at present lay sufficient stress on the value of local applications, more especially the caustics In the irritable, acutely sensitive spasm which scarcely admits of being touched with a bougie-point, which bleeds readily, and which we usually find in men of sanguine, irritable temperament, I have found the use of potassa fusa most effective. The manner in which I use it is as follows: I have a straight sound of small diameter (No. 4), with a platinum point, which receives and admits of a small piece of caustic, the point of which protrudes through a small aperture in the apex. I pass this rapidly down to the stricture, holding it firmly pressed against the obstruction until it yields. On withdrawing it a stream of water will almost invariably follow. If the case is an obstinate one of frequent recurrence, I use the potassa fusa. If it is recent, I prefer the nitrate of silver as less severe, and sufficiently efficacious. I have never seen any serious trouble follow the use of either remedy, and the only fear is an increase of the hæmorrhage; but this I have only seen in cases where the caustic has been too lightly applied, and the instrument withdrawn too rapidly. A few cases will illustrate the use of this remedy.

T. R., aged 32; subject to spasmodic stricture and retention. While travelling a distance by rail, spasm and complete retention came on. Came to the Hospital suffering greatly from distension. After hot-baths, opium, and numerous attempts too pass instruments had failed, the spasm yielded instantly to an application of potassa fusa.

J. S., aged 40; had been for some years subject to stricture, at times aggravated with spasm. Had recently been drinking hard, and an attack came on. After the failure of all the usual remedies, including the administration of chloroform, the spasm gave way to the use of the caustic potash.

With regard to permanent stricture, I think that we rely too much in our present mode of treatment on the rapid dilatation, forgetting that a stricture rapidly dilated, contracts as rapidly, and that really the best form of treatment is absorption of the stricture by long continued pressure. I was especially struck with the power of contraction of the urethra after rapid distension in four cases of calculus in the bladder in the female. In the first of the four cases distension was made gradually to extract a small stone. Sponge-tents were used for three days, until the forefinger could be passed into the bladder. In this case, after the removal of the stone, the patient suffered for a length of time from incontinence. In the other three cases the dilatation of the urethra was made rapidly; in one case a stone nearly one inch in diameter was removed in a little less than three-quarters of an hour. In all the cases the recovery from the dilatation was not only most rapid but complete, as in neither case did any incontinence remain. If we reflect for a moment that a stricture is nothing less than a cicatrix, we shall see how useless any sudden and intermittent dilatation must be. It may produce distension, or even rupture of the band of the cicatrix; but the subsequent contraction is just as rapid. I find the most effective treatment to be, to lay the patient in a recumbent position for a short time, and

pass the largest gum-elastic catheter I can into the bladder, fastening it securely. If much irritability comes on, I find a large dose of hyoscyamus, or, in severe cases, of opium, gives relief; or what is perhaps better still, a large opium suppository. On the third day I remove the first instrument, and there is usually little or no trouble in passing one a good deal larger. This done, the difficulties of the case may be said to be over. The urethra soon becomes accustomed to the catheter, and in a short time a free discharge down the sides of the instrument shows the process of absorption of the stricture. If in the early part of the case any rigor should occur, it need not cause alarm; or should the instrument be removed, it will almost always give way to warm fomentation, or the hip-bath, with a full opiate. The following (one of the most severe cases I ever saw) shows how effective this treatment may be, even with most unpromising cases:

A. T., aged 38; trainer of race-horses. Stricture of ten years' standing. Being a free-living, careless man, has allowed his disease to increase fearfully; has suffered on numberless occasions from retention, and his urethra is perforated in all directions with false passages. Owing to his being constantly in the saddle, and subject to great exposure, the disease was much aggravated, and the consistence of the stricture was almost horny. On the second occasion on which I saw him, I succeeded in passing a No. 3 gum-elastic catheter, which I recommended him to have fastened into his bladder. This he consented to, and on Nov. 17 he took to his bed. He kept me up nearly all the first night, as the irritability of the urethra was so great, and I was much afraid that I should be obliged to remove the catheter. He took during the night, 3 grs. of the extract of hyoscyamus. I also used a large quinine suppository. He was easier during the day, but the next night he was, if possible, worse. He was almost violent with pain and irritation, and continually tossing about in the bed. During the next day an offensive discharge commenced to flow down the sides of the catheter. A good deal of mucus also passed down the catheter, showing some considerable irritation of the bladder. Accordingly, to-day removed the No. 3, and replaced it by one two sizes larger; this was done with considerable difficulty and pain. At night he was again very restless, so much so that I was obliged for some hours to remove the catheter. I replaced it, however, early next morning, and kept it in until the 22d. I then replaced it by a No. 8. This caused him great pain at first, but by perseverance I was able to keep it in his bladder. At this time he had a full dose of opium in a suppository every night. On the 25th, I passed a No. 10, and his water, owing to its passing off more readily, became less offensive, though the discharge from the urethra was still great. From this time he continued to do well; his urethra became more accustomed to the pressure of the catheter. On the 8th of December, I removed the last catheter, a No. 12, from his urethra, he having been under treatment for twenty-two days. During the latter part of the treatment it is not at all necessary to confine the patient to his bed. This patient is now quite well; he passes a No. 10 sound for himself twice in the week to prevent the contraction of any remains of stricture; but he is able to follow his occupation with comfort. In this case success was only gained by the utmost obstinacy in the treatment. In most cases I found the irritation from the instrument to be less severe. There may undoubtedly be cases in which it is not possible to follow this plan of treatment, but when it is possible, I am convinced that it is the shortest and most effective method of cure.

ON CHOLERA.

By A. CLARK, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

Lecture VIII. Part I.

The Treatment of Cholera.

We may now inquire whether any treatment is curative in the several stages of cholera. It is generally believed that the diarrhœa of the first stage, if sufficiently prolonged to permit the application of medical precepts, is as easily cured as a diarrhœa of any other kind. This is not quite true. A diarrhœa in cholera seasons is more dangerous and less uniformly manageable than in ordinary seasons when cholera is not prevailing. At the same time, here is the great field of professional usefulness; this is the period of the disease when cures should be effected. Then what are you to do? First, send the patient to bed, and let him have the advantage of warmth and rest in the recumbent position. It is well to obtain a little diaphoresis—not profuse sweating, but a soft skin, or gentle perspiration, such as may be caused by a warm bath, or better, by a foot bath. The administration of cathartics is not generally thought proper; and this is especially true of the salines. Indeed all cathartics, while cholera is threatening, should be avoided as far as possible in those not attacked. Many an instance has come to my knowledge of cholera apparently precipitated by the administration of medicines of this class. Castor-oil is the least objectionable, and I can conceive may, under certain circumstances, be serviceable; for example, when a diarrhœa has been provoked by accumulated fæces in the intestines, or by errors of diet, or by the indigestible portions of certain fruits. In general, the first aim is to check the diarrhœa. Among the medicines that we use for this purpose, opium or an opiate almost always finds a place. A favorite prescription in past epidemics is the following:—"Tinct. opii, spt. camphor, tinct. capsici, tinct. catechu, tinct. caryoph., equal parts. Of this a teaspoonful more or less frequently according to the urgency of the symptoms.* Those who entertain the view that this is a disease which replaces miasmatic fevers, advocate the use of quinine. Indeed, it is claimed that quinine alone will suppress the discharges. The astringent preparations of iron have some reputation, as the pernitrate, or the persulphate, with or without quinine. A pill that Dr. Houston thinks as serviceable as any, is made up thus: Acetate of lead and camphor, each twenty-four grains; acetate of morphia, two or three grains; oil of cinnamon, five drops; mucilage of gum arabic, sufficient. This is made into twelve pills, and one to be given every two, three, or four hours, according to the nature of the case. Another favorite prescription is what is called Hope's mixture. Its composition is as follows:—Nitric acid, one drachm; camphor mixture, eight ounces; these to be mixed, and afterwards the tincture of opium added to the amount of two scruples. One quarter of this makes a dose, to be repeated more or less frequently.

* Dr. Squibb, in "Advice upon Epidemic Cholera," lately published, gives the following formula, which he thinks more useful by the addition of chloroform. He proposes to call the preparation the "Compound Tincture of Opium," or "Diarrhœa Mixture." It is tincture of opium, spirits of camphor, and tincture of capsicum, each one fluid ounce; purified chloroform, three fluid drachms, and a sufficient quantity of stronger alcohol to make the whole measure five fluid ounces. He advises a teaspoonful as a dose, to be taken after each stool. If the diarrhœa increases he would double the dose. The mixture is suggested for popular use till a physician can be obtained.

If the diarrhœa begins after a surfeit, or there is reason to suppose there is undigested food in the stomach, a quick emetic is regarded as important. Alum, the aromatic confection, the compound spirits of ammonia, chalk mixture, hæmatoxylon, kino, and calomel in grain doses, are in the list of remedies for this stage; each, however, is given with opium or its tincture. But none of these medicines, regarded as astringents, are as highly valued by the English physicians as the acetate of lead. It is given with opium, one to eight grains of the acetate, and one quarter of a grain to a grain of opium; in the small doses, every hour. Some physicians claim success in the use of the pulvis cretæ compositus cum opio; others prefer hydrargyrum cum creta, and Dover's powder. These will, some of them probably, answer your purpose; but rest in bed is regarded as more important, perhaps, than any special medication.

Passing to the serous diarrhœa—the symptom soon attended by cramps and vomiting—the question comes whether any particular remedy is specially serviceable. Dr. Fuller—the same, I believe, who has made a high reputation by his treatise on rheumatism—holds that sulphuric acid, first suggested by Mr. W. S. Cox, of Kensel Town, England, has almost sovereign power over this stage of the disease. His mode is to add to eleven ounces of water one ounce of dilute sulphuric acid, and to give of this three tablespoonfuls every half hour; and he claims that it is infallible; but we hear of so many infallible remedies for cholera in its various stages that we have come to doubt infallibility, even in Dr. Fuller. With this, he sometimes combines in the alternate doses, half a drachm to a drachm of chloric ether. He occasionally commences the treatment by administering two grains of opium. He sometimes adds five grains of calomel in one dose. He also employs sinapisms to the stomach, and friction to the extremities. This treatment has the support of some good names in England. M. Worms, of Gros-Caillou Hospital, uses sulphuric acid in sweetened water, one part to three or four or five hundred, as a drink, and attaches great importance to it. Dr. Hutchinson however, in 1854, says: "Sulphuric acid, so highly recommended by Dr. Fuller, was prescribed, but without any benefit."

Sulphur in substance has been proposed, and the suggestion comes from the idea entertained by some persons that the disease is caused by vegetable fungi. Dr. Grove takes of precipitated sulphur, one drachm; bicarbonate of soda, one drachm; compound spirits of lavender, six drachms, and of water two ounces, to make a mixture; of this he gives a tablespoonful every half or quarter of an hour. This is for him a most serviceable remedy. He says that it checks the serous discharges and restores warmth. He refers to the experience of some of the Scotch people, who treated themselves for what was supposed to be cholera with great success, using only brimstone and whiskey. He refers also to the *London Practice of Physic*, 1692, in which sulphur and the alcoholics are spoken of as the only means of curing a severe and fatal diarrhœa which prevailed in England about that time. The suggestion of Dr. Grove has the support of Dr. Cormack, and may be tried; but I fear it will share the fate of all cholera specifics.

Creasote, says Dr. Cormack, if the patient does not refuse to take it on account of its odor, hardly ever fails to arrest the serous discharges. Two or three drops given every hour or two, it is claimed, will constrict the vessels and stop the diarrhœa. This may be the language of hope, but it is not the language of science. That creasote may be serviceable is very possible; but to say it hardly ever fails, is but to bring discredit on him who says it.

In the treatment of the third stage of cholera, chloroform has gained considerable reputation. It was used by the late Professor Horner, of Philadelphia, in the cholera of 1849, and used with some success. Dr. Hartshorn, of Philadelphia, has presented to the profession what he regards as a useful formula:

℞. Chloroform., f ʒ ij.
Spt. Camph.,
Tinct. opii, ā ā f ʒ iss.
Ol. cinnamom., gtt. viij.
Alcohol, ʒ iii.
M.

Professor Horner and Dr. Hartshorn gave chloroform in collapse, a few drops every few minutes, combined with camphor and laudanum, and the latter thinks its success extraordinary. Of Dr. Hartshorn's prescription five to thirty minims or more are to be given, with ice internally and warm applications externally. Dr. Davies (Dr. Gull's Report) had at one time very great confidence in chloroform in the stages of serous diarrhœa and in collapse, and gave it in doses of seven to ten drops every quarter or half hour, claiming very great success; in nine cases of cholera and thirteen of the worst diarrhœa, only one death; in fourteen cases treated by Mr. Tower, under Dr. Davies' observation, only one death, and so on. In subsequent reports his trust in chloroform is gradually more and more shaken, till in his fourth and last he says he has lost confidence in it when used alone. On the whole, summing up all the reported experience which I have been able to find, it cannot be claimed that this medicine has any great curative power. It often allays the vomiting and cramps, and is worthy of further trial. Chloroform has been used by inhalation, and the effect of its use in that manner is to allay the cramps and suspend the vomiting, but unfortunately the patient must be kept continually in a state of slight anæsthesia, or these symptoms will return. Its administration does not seem to have materially diminished the mortality from cholera, though it has doubtless rendered the disease less painful, and may be worthy of use for that purpose.

Strychnine is very warmly advocated by Professor Fraser, of McGill College, Montreal, to be used in impending collapse, together with the means which tend to stop the discharges. He reports twenty-five cases treated by it, in doses of one-forty-eighth of a grain, dissolved in acetic acid and alcohol, repeated every quarter of an hour, sometimes every five minutes, until six or twelve doses are given, or till there is a reaction or specific effects. Twelve doses would make one-fourth of a grain. He thinks it has great power in sustaining the action of the heart and capillary vessels. His success he reports as twenty saved; and of the five others, one only died in collapse, the others in the stage of reaction. I have had no experience with the drug given as here suggested; but as it was used together with means to stop the discharges, and these means are not specified, it is pertinent to inquire how the credit of these cures should be divided. This suggestion was made near the end of the last epidemic (1854), and there has been little opportunity to test its value.

Now, of collapse. *Electricity* has been tried. It seems to revive the energies for a little time. The current has been passed from the neck to the epigastrium, to excite the action of the diaphragm, and from side to side to stimulate the heart. In one patient of Dr. Peacock, a child, the temperature in the mouth rose from 88° to 92°, and the pulse became fuller under the influence of this agent, and the patient recovered; but the same physician was not able to sustain this success. Galvanism has a similar power. But, all

considering, we may say of electricity and galvanism, that while in collapse they have the power of increasing warmth and bringing back the pulse temporarily, it is doubtful whether they have yet saved a single life. The *wet sheet*, used after the manner of the hydropathists, was tried pretty extensively in England during the epidemic of 1849. The result was a slight reaction, but it did not gain the grade of a curative agent. *Affusions* have been tried. Patients have been placed in a warm hip-bath, and both warm and cold water suddenly poured over the head, shoulders, and body. This is done quickly, and the patients are immediately placed in bed, in warm blankets. This plan has the power of producing some reaction, and is on the whole thought favorably of. Its effects are said to be better than those of the hot bath. *Oxygen* has been used in collapse by inhalation in a few instances, but it does not seem to have gained favor, because the temporary good effects have been followed by unfavorable results. The patients have almost all died. *Counter-irritation.*—Caspar dipped cloths in alcohol, laid them upon the abdomen, then set them on fire; but the patients did not get well for all that. Indeed it is striking that this sort of cauterization did not seem to produce much redness upon the surface to which it was applied. Milder counter-irritation, however, is generally resorted to; stimulating applications and warmth in various ways; mustard to the abdomen, the legs, and chest, particularly to the epigastrium, is hardly ever omitted. I do not suppose we can say that rubefacients, so used, have been of any *signal* service. They have the negative merit of innocence, and probably the positive one of arousing, in some degree, the failing nerve powers, and of quickening somewhat the capillary circulation. *External warmth*, notwithstanding it is often disagreeable to the patient—notwithstanding his cold arms feel heated—is pretty generally received with favor. A moderate degree of artificial heat aids in restoring to the body its natural temperature, and improves the chances of recovery. *Emetics* have been proposed—of common salt, or mustard, or sulphate of zinc, or ipecac.; and the result of experience seems to be that they do to a certain extent arouse the heart to activity, that they bring a little warmth to the surface, and for a moment distribute the blood a little more evenly through the body. But they are not curative; their effect is temporary, and the discomfort they produce is often considerable. They may be useful in another way. One who has seen little of the disease can hardly understand why the vomiting it produces should not prohibit the use of emetic drugs; but that vomiting, though it may cause the ejection of a great deal of fluid secretion from the stomach, is not forcible and violent, and often leaves undigested food in the organ. This is demonstrated in examinations after death. Such undigested food has been found after two days and more of vomiting. To remove this is to remove a source of irritation, and an emetic will often do it. *Ice, and cold drinks.*—A distinguished writer on the treatment of cholera remarks that it is gratifying to find that the experience of the last epidemic has confirmed the whole profession in the use of ice and cold drinks for those in collapse and approaching collapse. The burning thirst is allayed by swallowing portions of ice. It is true that we have to contend with the disposition to vomit; but the chances of the patient seem to be improved in two ways—by relieving suffering, and supplying to some extent water, which his blood lacks. Cold drinks and ice, then, have been received with extraordinary favor; and though not heroic measures, if they palliate only, they give nature a better opportunity to do a kind act. Dr. Murray, in India, states that *injections into the rectum, at a temperature of* 120°, were in his hands of great service in restoring warmth to the body and giving force to the pulse. He used a weak solution of common salt and carbonate of soda, a pint at a time, and repeated it every half hour, or less frequently. The injections were usually retained but a few minutes, yet sufficiently long to produce recognisable effects. It may seem that giving cold fluids by the mouth, and heated ones by the rectum, cannot both be defended; that one would neutralize the effects of the other. But cold applied to the mucous membrane, in the upper part of the alimentary canal, diminishes the hyperæmia, the irritation, and the vomiting; while the injection falls upon a membrane less likely to be engorged, and probably increases the warmth of the body without doing any local mischief. Dr. Joel Foster, of this city, informs me that he has used warm injections for this purpose with advantage, and thinks he can cause them to be retained for a longer time by holding a compress against the anus.

Considerable success has been claimed in behalf of a *saline solution*, first proposed by Dr. Stevens, then of Jamaica. Believing that analysis showed some loss of saline constituents of the blood, it occurred to him that these could be restored by administering salts dissolved in water whenever the patient could retain liquids. Drs. Gull and Baly inform us that at the Cold-Bath Fields Prison other modes of treatment were tried, and the patients all died; the number was not very great, however, treated by other plans; for after five or six had died, the physicians adopted Dr. Stevens' method. The result was, that of patients so treated in the prison hospital, and in a lane in the neighborhood, forty-four out of forty-six recovered. This would be extraordinary success if the patients were all in the dangerous stage of the disease. Figures, as I have said, are uncertain guides when not attended by full explanations; yet we have but little else to trust, and so must do the best we can with them. The mixture used on this occasion was, bicarbonate soda, half a drachm; common salt, one scruple; chlorate of potassa, seven grains; repeated every hour in such quantity of water as might seem expedient at the time of prescribing. Another solution has been used also, which is: common salt, half a drachm; tartrate of soda, twelve grains; phosphate of soda, eight grains; dissolved and taken at a draught. With reference to the appropriateness of these prescriptions, I may say a word when I come to another branch of the subject. This saline treatment of Stevens, though received with extraordinary favor in certain places, has not been successful in others; and the summing up by Gull and Baly is substantially this, that while at times it seems to have aided recovery materially, at other times it seems rather to have increased the evacuations and the danger. It has at least this merit—that when it is mainly relied upon, more dangerous medication is avoided. *Camphor* is a medicine that has been used pretty extensively in all the stages of this disease. In the collapse it has the reputation of allaying the cramps in a certain degree, and lessening the irritability of the stomach, and consequently the vomiting. It is certainly a safe medicine, and is believed to be as good a diffusible stimulant as can be used; and given in solution in chloroform, is perhaps of some advantage.

I have here a manuscript paper which was sent me in 1854 or 1855 by Dr. O. H. Smith, then of Williamsburgh, now of New York, giving a summary of the treatment of cholera in the hospital of which he had charge in 1854. It contains one statement which I think is worthy of consideration. I present it to you in his own words: "Sulphuric acid, so highly eulogized by Dr. Fuller, of St. George's Hospital, was prescribed, but I could get

no good results from its administration. Strychnine, as recommended by Prof. Fraser, of McGill College, was given, and I think it may have had some effect in postponing the period of collapse; but I do not think it had any control over the rice-water evacuations. I gave this remedy in view of the opinion that cholera poison acts especially on the gauglionic nerve centres of the abdomen; but its effects were such that I put it down as a doubtful as well as dangerous remedy. I tried the oxide of bismuth. It seemed to have no control over the watery discharges; but I think it relieved to some extent the retching and vomiting, so constant after the discharges had been arrested. In all cases the abdomen was enveloped in strong mustard poultices." Dissatisfied with all these agents and means, except the last, Dr. Smith turned to brandy.* "To restrain the rice-water evacuations," he says, "I have ordered an injection into the bowel, containing an ounce of brandy, two or three ounces of strong tea, and five or ten grains of the sugar of lead, to be repeated after every discharge. At the same time I ordered a soft pill, containing quinine, calomel, and camphor, of each half a grain, to be given every fifteen or twenty minutes; the whole abdomen being covered with mustard poultices. The patient was also directed to take brandy and water every five minutes by the mouth." The vomiting and dejections soon ceased. The feature of this treatment which has been but little if at all tried, is the injection of diluted brandy into the intestines, and it is to this that Dr. Smith attaches chief importance; but he found that brandy diluted with water was equally beneficial. His results induce me to commend his method to further trial, notwithstanding the general opinion which is adverse to the use of stimulants of this kind during the particular stage of which we are now treating. Dr. Smith here reports the cases of two children having rice-water discharges, to whom the parents administered two or three tablespoonfuls of brandy in each case, and made the children fairly "drunk;" the discharges ceased—none occurred after the full effects of the brandy were felt. These cases taken alone, would argue strongly in favor of brandy and the free use of it. But two cases will hardly affect a rule derived from the observation of several epidemics.

There is another mode of treatment, if it can be so called. A considerable number of physicians having charge of cholera hospitals, observing the ill-success of all plans of treatment, have felt justified in leaving a number of patients without any treatment besides cold drinks and ice to satisfy their thirst, and proper bedclothes. Dr. Hutchinson says, referring to some he left in this way, that "The most valuable experience derived from the observation of the recent epidemic (that of 1854) is, that cholera patients should be disturbed by remedies as little as possible. And when in any case we are at a loss to know what treatment to adopt, or if we find the patient growing worse under the influence of remedies that we think best adapted to the case, the better plan is to rely on the *vis medicatrix naturæ*. This I have repeatedly done with much satisfaction; patients in the deepest collapse having reacted without any treatment; in one case without even ice, beef-tea, or external applications." Again he says: "When the vomiting proved obstinate, nothing but lumps of ice and teaspoonful doses of beef-tea were allowed; but frequently even these were withdrawn, and the patient permitted to remain unmolested by any kind of treatment for twelve, fifteen, or twenty hours, with the most satisfactory results, even when there was great depression of the circulation, the skin cold and cyanosed, and the rice-water discharges continuing." Other physicians have made similar statements. Dr. Hutchinson's mortality was, however, not very light. He treated one hundred and seventy patients in his hospital, of whom ninety-seven died; eighteen were in the first stage, and all recovered; seventeen were in partial collapse, of whom one died; one hundred were in complete collapse, of whom eighty-two died; five died in the consecutive stage out of nine; and nine of other diseases, including diarrhœa, out of twenty-six. It does not seem then, do the best we can, that we have any great control over this stage of collapse.

Now a few words regarding injections into the veins in collapse; not because they have been established as useful, but because the results, however temporary, are very interesting. The plan was first proposed and put in practice by Dr. Latta, of Leith, Scotland. He used a saline fluid. He adopted for his injections this formula: two or three drachms of common salt; two scruples of subcarbonate of soda, in six pints of water, to be injected at a temperature of 112°. He selects this temperature because, he says, if it is cooler it produces a chilly feeling in the patient; and if it is much warmer, even as warm as 115°, it stimulates the heart too much, and produces a sense of weakness and fainting. The report of his first experiment I will read you in his own words:

"The first trial was made upon an aged female, whose case was utterly hopeless (indeed he feared she would die while he was making the preparation). Having inserted the tube in the basilic vein, anxiously I awaited the effects; ounce after ounce was injected, but no visible change was produced. Still persevering, I thought she began to breathe a little less laboriously. Soon the shrunken features, and sunken eye, and fallen jaw, and face pale and cold, bearing the manifest impress of death's signet, began to glow with returning animation; the pulse, which had long ceased, returned to the wrist, at first small and quick, but by degrees becoming more and more distinct, fuller, slower, firmer; and in the short space of half an hour, when six pints had been injected, she expressed herself in a firm voice, saying she was free from all uneasiness; she actually became jocular, and fancied all she wanted was a little sleep. The extremities were warm, and all the features bore the aspect of comfort and returning health (but hear the sequel); the purging and vomiting soon returned, and she died five and a half hours after the operation."

This, unfortunately, is the history of very much the larger number upon which this experiment has been performed; of almost all. Dr. Baly says he has attempted this medication in six cases, and all have died. Dr. Streeter says that the experience of the epidemic of 1849, in England, has settled the question, has determined the inexpediency of a resort to these injections. Dr. Latta, however, reports another case. It is his first, perhaps his only, successful one. The patient was a female aged fifty, whose condition was hardly more hopeful than that of his first case. He injected one hundred and twenty ounces of the solution, the effect of which was magical. He says: "The restoration appeared to be complete, but the diarrhœa returned, and in three hours she was again prostrated. Again he injected one hundred and twenty ounces of the same solution, and again he had favorable results. In twelve hours three hundred and thirty ounces had been injected, and the reaction was fairly established.

* I have to-day (July 18) received a letter from Dr. Smith, in which he informs me that Drs. Walser and Bissel, in the quarantine ships, speak favorably of brandy injections; that Drs. Otis and McLean have each treated a case on his plan with good results. These cases will be published in the RECORD. Dr. Dalton, Sanitary Superintendent, informs me that as far as he can judge from three or four cases reported to him, there is a probability that these injections will be useful.

In forty-eight hours she smoked her pipe. She was afterwards taken to the hospital, where she had some typhoid symptoms, but finally became convalescent." Dr. Lowery states that he has performed this operation twenty-six times, and had four successful cases, and believes that the injections must be introduced slowly. If as good a result as that can be obtained with any degree of uniformity, it would seem proper to resort to the operation, because cases in extreme collapse are the only ones on which it is ever attempted—cases regarding which there can be entertained no reasonable hope from any other method of treatment.

Dr. Johnson states in his "Notes" that Dr. Mackintosh has performed this operation on 156 patients, having had 25 recoveries and 131 deaths, and thinks that such a mortality is "frightful." It corresponds very nearly with that of Dr. Lowery's cases; and supposing all the patients to have been *in extremis*, I should be unwilling to adopt this epithet. It may be true "that if all these 156 patients had been left without treatment a larger proportion would have recovered;" but it is at least a fact worth knowing, that about one in six of those whose veins have been filled with this very crude imitation of blood constituents could survive the experiment. To my mind it gives the hope that a better method may be attended by greater success.

It is reported, though I don't know who performed the operation, that in 1832 there was a single successful case in this city. Drs. Gull and Baly, in summing up the history of this treatment, seem to be of the opinion that it is worthy of further trial; though Dr. Streeter regards it as completely condemned. Dr. Hutchinson used saline injections in five cases, "but with only temporary benefit." Yet he thinks that when a proper liquid is found, the proper temperature determined, the rate of injection and the quantity fixed, and when skill has overcome the difficulties attending so delicate a procedure, it may still be capable of saving lives that would otherwise be lost. He used a solution containing three drachms of common salt and one drachm of alcohol to a pint of water, at a temperature of 100° to 115°, injecting two pints; and repeating when the algid symptoms returned. He also used the solution by Dr. Gull which I will give you directly. But here let me remark that it does not seem to me that a complex formula for the preparation of the fluid for injections is at all necessary. The object, of course, is to restore that which has been lost—and that is chiefly water; the evacuations from the bowels and the vomit are composed chiefly, as you will remember, of water, salt, and albumen, or albuminose. Then there is the intestinal epithelium, and nothing else of importance. In the examination of the blood, most analysts, except Dr. O'Shannessy, have reported an increased proportion of saline materials in the fluid which remains in the body. If there is then an increased proportion of saline materials, what the blood really wants is water, and not salts and water. If I were about to attempt an experiment of this sort, I would use either simple distilled water, or water with a very little common salt added.* Dr. Gull's formula is as follows—chloride of sodium, six parts by weight; chloride of potassium, the same quantity; phosphate of soda, three parts; carbonate of soda, twenty parts; of this mixture of salts one hundred and forty grains are to be dissolved in forty ounces of distilled water, and filtered. Filtering is important, because dust gets into all these substances when exposed.

I have here a pamphlet, published in Canada in 1854, containing a report of seven experiments of injecting cow's milk into the veins of persons in a collapsed state. The report is drawn up by Dr. Borell; four of the trials were made by himself. He had two recoveries. A friend, who attempted it in three other cases, failed in each. The experiment was conducted in this way. A cow was brought near to the sick person, and the milk was used of the natural temperature and immediately; the bowl which held the milk was warmed and the syringe was warmed. The amount of milk used was eight to twelve ounces. My impression is, that the quantity of fluid should be considerably increased; it does not correspond at all, in these experiments, with the quantity of fluid usually lost in the dejections; yet the success is two in seven. In the other cases there was some revival of the vital powers, but they sank again; whether they would have been again revived had the injection been repeated, we cannot now decide. The pamphlet is an interesting one, containing the reasonings by which Dr. Borell came to the conclusion that it would be safe to inject milk into the veins.

I return once more to Dr. Johnson, to state to you his views of the treatment of cholera. You will recollect that he regards the evacuations as salutary in eliminating the poison that oppresses and may overwhelm the vital powers. I may here say, that this is not a new opinion. Dr. Johnson does not claim that it is original with him. Many physicians have been led to the same conclusion, some of whom he quotes. Dr. Hutchinson, whose paper I have often referred to, a close observer, has come to the same conclusion. He says: "Whenever a patient was admitted into the Brooklyn Cholera Hospital with copious and frequent vomiting and purging, especially of rice-water fluid, if the discharges were not involuntary, a favorable termination usually occurred, and *vice versa;* and instead of death being the consequence of such symptoms, the conclusion seems more rational that they are curative means adopted by nature to eliminate the poison from the system. Instead, therefore, of arresting the discharges, it was deemed best *to let them stop.*" Dr. Johnson goes beyond this; he is not satisfied to let them stop, but would augment them by mild cathartics, emetics, and enemata. He asks us to admit that calomel, if it cures, acts not as an alterative, or sedative, or cholagogue, but as a cathartic; that the saline mixture of Dr. Stevens is really efficacious, not because it restores the lost salts, but because it is a laxative; and he urges that the English physicians in India treated the disease with more success than the European physicians, because they were not afraid to give cathartics and at the same time call them by their right name. Dr. Johnson, in 1855, reported fifty-four cases of cholera and choleraic diarrhœa treated on this plan.—(*Epidemic Diarrhœa and Cholera, &c.*)

I have examined with some care these cases, and I am compelled to admit that I do not know any detailed reports that give better results. It is not to be forgotten, however, that the cases all occurred between the 11th of August and 28th of September, 1854; in other words, in the decline of the epidemic in London. The seventeen cases of choleraic diarrhœa all recovered; and of thirty-seven cases of cholera, all reported to have been in collapse more or less severe, twenty-three recovered. Many of these cases appear to me to have been mild; some that were considered as in collapse present very few of the symptoms of that state, but the cases numbered 2, 7, 8, and 48 were severe enough to test the virtues of any treatment, and they recovered.

* Dr. A. N. Gunn, late Health Officer of this port, stated in the Academy of Medicine, since these lectures were delivered, that in 1832 injections of saline fluid were unsuccessful in the Hospital to which he was attached as assistant, and had been forbidden; and that afterwards, as he believed, three or four patients were saved by injecting into the veins pure warm water.

The great feature of the treatment is the administration of castor oil in half-ounce doses every half hour for several hours, then the same dose every hour, and later every two or three hours. Thus varied in frequency, these doses are continued usually from one to four days. In one instance recovery followed ounce-doses given every hour till five were taken. In one case (8) of extreme collapse a girl nine years old took fourteen doses of an ounce each between 7 A.M. and 5½ P.M., then after an interval of nine hours she took seven half ounce doses in ten hours; at the end of twenty-four hours half an ounce, and three days later another half-ounce, which last portion seemed to stop a diarrhœa that had continued during convalescence. She took in all eighteen and a half ounces of castor oil. In another case (17) of collapse, the patient took in half-ounce doses twenty-two ounces of the oil during the first day, but vomited nearly all of it; the second day and following night he took seventeen ounces, very little of which was vomited. The purging produced, the author thinks, was hazardous, but the patient revived. One patient (48) took thirty-five ounces of oil in a little more than four days, having vomited during this time 125 times. This quantity of oil, the author thinks, was twice as much as was required. The patient recovered.

I do not discover in the examination of these cases any precise rule relating to the quantity of oil to be given. If it caused vomiting it was still acting as an evacuant, and was not discontinued for that reason. If it did not act in this manner, an emetic was administered in some of the cases. In full collapse Dr. Johnson seems to prefer mustard and salt as an emetic, and gives it before the oil is taken. When the oil does not prove cathartic, he uses salt and water enemata. In some instances he gave calomel with the oil, two to five grains, and if in the smaller doses, it was repeated three or four times. He applies warmth to the stomach and extremities, and uses other adjuvants, but does not speak favorably of ice and cold water, because he thinks they suspend the elimination of the poison. Such is the plan for which Dr. Johnson asks free but unprejudiced criticism. In the present state of our knowledge theoretical criticism goes for very little. The single question is, will this method save more lives than any other? In Dr. Johnson's hands it has done as well at least as any other of which I have seen the detailed reports; but the trial alone can teach us what it can do at the commencement of an epidemic. He does not claim that he has found a specific for cholera He says, indeed in "Notes on Cholera," p. 87: "There is no remedy which has the slightest pretensions to be considered a cure for cholera; no drug or agent which, so far as we know, will neutralize the poison or lessen its virulence. I have not the faintest hope or expectation that a specific remedy for such a disease as cholera will ever be discovered." While I would not discourage the attempts to cure cholera by evacuants, and do not doubt that Dr. Johnson's results are as satisfactory as almost any that have been published, allowance however being made for the stage of the epidemic to which his practice was applied, yet there is a pertinent inquiry regarding the first stage of the disease. How does it happen that agents which restrain the discharges are so efficacious in that stage? It is the almost universal practice to give them, and this of itself is one of the strongest proofs that they are proper and useful. If the poison can be eliminated by emetics and cathartics, it would seem that this is the stage in which they should be most demanded, and in which the agents which suppress discharges would be most harmful. We know but little about the modes in which animal poisons are eliminated; we do not know indeed that they are eliminated at all through the evacuations; we know that some of them, or rather portions of some of them, escape from the body, as in small-pox; but this is not an elimination that purifies the sick man, or relieves him of a single bad symptom. The poisonous principles of typhus and typhoid fevers, of measles and scarlet fever, are not eliminated before the patient begins to recover; for these diseases are communicable during convalescence. The diarrhœa of typhoid fever does not diminish the danger of the patient. Intermittent fever is suspended while the miasmatic poison still remains in the system. There is no evidence whatever that it is in the power of drugs to extract a miasmatic or an animal poison from the body, and so purify it, say what we may of depuration. Still, Dr. Johnson is not to lose the credit of his experiment. Many of his patients recovered while taking castor oil. That fact will stand, whatever its explanation may be.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

INFORMAL MEETING, JULY 5, 1866.

DR. JAMES ANDERSON, President, in the Chair.

THE Academy held an informal meeting on the evening of the 5th of July, there being not a full quorum present.

DR. A. N. BELL of Brooklyn, who had been appointed at the last stated meeting to remark upon disinfection by superheated steam, at the request of the members reported progress and gave a history of the circumstances which first led him to consider that agent a powerful and efficient one. While in the naval service many years ago, the captain of the ship of which he was the medical officer suggested to him the propriety of steaming the vessel for the sake of getting rid of the vermin. This was done, and with such good effect, without any injury to the vessel, that the thought occurred to the Doctor that steam might, by virtue of its destroying powers upon all organisms, be used for the purpose of disinfection. In the instance referred to, no account of the temperature of the steam was taken, but it was nevertheless sufficiently high to re-evaporate the vapor that might otherwise have remained on the walls of the compartments and leave them perfectly dry. Having had charge subsequently of a hospital-ship, he had an opportunity for testing the effects of steam in its power to control yellow fever, and he expressed his belief that it would be equally effectual in arresting the progress of cholera. The question whether steam could be sufficiently heated to destroy every known organism, he maintained was now definitively settled, inasmuch as 284° Fah. had succeeded in decomposing the lowest possible organism. He proposed to apply 300° of heat, which certainly left a margin for contingencies, and he thought that he would be able to promise a certain and complete destruction of every known organism. This immense heat, he contended, did no other harm than blistering the paint or melting the turpentine in the wood, the moisture being entirely re-evaporated by the high temperature. He then recited some experiments which he had made at the instance of the Health Officer, Dr. Swinburne, at Seguin's Point. By throwing superheated steam into a room, he raised the temperature up to 280° Fahr., as proved by a self-registering thermometer, and at the end of five minutes the doors were opened, and everything was found perfectly dry, while some eggs and

oysters which were contained in the apartment were cooked. In another similar experiment of ten minutes' duration, the only change that was noticed was in the moistened state of the temperature in the pine boards. He thought it necessary that the temperature should be preserved continuously for two hours in order to have its full and desired effect. He stated, in conclusion, that he had placed at his disposal by the Health Board one of the metropolitan fire-engines, with which he proposed to give some public exhibitions as to the utility of superheated steam as a disinfectant to such as might be interested. He did not desire that these few desultory remarks should be taken as a formal report, but promised at a future time to present his conclusions in full to the Academy, when the various experiments which he intended making should be completed.

A DISINFECTING CHAMBER-PAIL.

The PRESIDENT then exhibited Rankin's Disinfecting Chamber-Pail. The pail is an ordinary one, but has applied to the under part of its cover an apparatus by means of which disinfecting materials can be made to fall on the stools. The cover is hollow; its lower platform is supplied with triangular openings, the apexes of which point towards the centre. Upon this platform there is another one of the same size with like openings. By means of a spring attached to a knob passing through the top of the cover, the lower platform of the cover is kept closed by the upper one. When the stool has been passed and the lid closed, this knob is turned, and the openings of the two lower platforms correspond, and the powder or other disinfecting material falls into the vessel, when by letting go the handle the reservoir containing the disinfectant is shut.

DR. GRISCOM remarked that this was a very excellent apparatus, and would serve the double purpose of not only disinfecting the dejections, but would help to purify the sewers.

The question as to which was the best and cheapest disinfectant then came up, when Dr. Harris stated that sulphate of iron as a powder ranked first, and the refuse of coal tar as a fluid took the second place. Both were very cheap, but the former would probably be the most popular.

DR. HAMILTON remarked that Rankin's apparatus could not very well be applied to the water-closet. The apparatus was only intended for powdered disinfectants, and if adapted to the water-closet, these powders would become more or less moistened by the splashing of the water from the basin below, and would corrode the vessel which contained them. He thought an improvement might be made upon the apparatus by having it adapted for fluids.

The PRESIDENT then stated that such improvement could easily be made by having a pipe containing the disinfectant so connected with the one leading the water into the basin, as that both could be acted on at once by pulling up the knob in the seat.

DR. HARRIS remarked that it was very necessary not only to have a disinfecting apparatus connected with every privy and water-closet, but it was equally necessary to have some arrangement contrived whereby the apparatus would be self-acting. This was particularly desirable in all public water-closets. If some such arrangement had been made, he thought that the cholera in Elizabethport, N. J., might have been probably prevented from spreading even as far as it did. He then gave an account of the epidemic as it prevailed at that place:

A short distance from Elizabeth City is Elizabethport. The Germans from the latter place are in the constant habit of wandering up through Elizabeth City, some to take transportation by railway, and others to tarry in the city. About three-quarters of a mile from Elizabethport there is a street called Schuler street, which is occupied almost entirely by Germans; only one rookery being occupied by the Irish. In that street a number of German families tarried, some of whom had been on board of cholera ships. These facts were stated to their friends. About five days after a man with diarrhœa had left with his family, the people in the neighborhood began to suffer from cholera. The first case, a man with a large family, was traced to the patient who had diarrhœa as the cause, the former having been, it is said, in the habit of using the same privy as was used by the latter. This first case of cholera was attended by a devoted daughter, who was the next victim to the disease. The soiled clothing of the father was found in the room, and some of the furniture had seemingly been spattered by it. The evacuations, such as could be collected, were removed to the privy, without, however, being previously disinfected. The little girl was attacked the morning after the father's death. The former survived eighteen hours after the first onset of the disease, while the girl died nine hours after. Seven other cases died in the same house, all being in the habit of using the same privy.

The mayor of Elizabeth hearing of the epidemic, and being a physician, determined to stay its progress by destroying the albuminous fluids wherever found. This he did at the cost of $3,000, which was afterwards refunded to him by the City Council, who approved of the means adopted.

The first case occurred on Monday morning, and the last terminated by Saturday night. Notwithstanding that the inhabitants were in a fit condition to invite the epidemic, and were in fact only waiting for its fearful ravages without attempting to guard against it, yet by the simple means adopted by the mayor, the epidemic ceased at once.

DR. HAMILTON favored the reference of Rankin's apparatus to a Committee for the purpose of making some improvement in its construction in accordance with the suggestions made.

DR. GRISCOM thought that the chamber part was perfect in itself, but was of the opinion that a separate contrivance might be more serviceable for the water-closet.

DR. RICHARDS suggested that the people might be instructed to introduce their disinfectants into the tank above the water-closet, whence it would descend in solutions directly into the basin below.

A Committee, consisting of Drs. Griscom, Hamilton, Post, and Harris, were appointed in accordance with the previous request.

The meeting then adjourned for the season.

THE CATTLE PLAGUE IN IRELAND has abated in the north, but has appeared in the south, particularly in the county of Wexford. An order in Council issued in Dublin stops all fairs, sales of cattle, etc., in certain baronies of Down and Antrim, but allows the sale of cattle for immediate slaughter, except within the actually infected district. A dispatch from Dublin says that confidence has been greatly restored in Ireland by the promptness of government, and it is now hoped the plague will not extend. A cordon has been drawn round the infectant district.

MEDICAL OFFICERS OF THE FREEDMEN'S BUREAU in Tennessee, are hereafter to be appointed by the State instead of by the General Government.

Progress of Medical Science.

Professor Arlt on Gräfe's new Method for the Extraction of Cataract.—At a meeting of the *Imperial and Royal Society of Physicians in Vienna*, held April 27, 1866, Professor Arlt spoke as follows: We could make the objection to the flap operation, which has given extraordinary results, that even when the operation was performed with extreme accuracy, here and there an eye was unexpectedly lost. This often happened through an unfavorable condition due to the patient; in other words, the cause of the bad result lay in the constitution of the one operated upon, and chiefly in the fact that the wound healed badly. Of less consequence are the cases in which the operation does badly on account of one or the other mistake in the operation itself. The difficulty in the remaining behind of parts of the lens, has been, as far as possible, obviated, and their removal is no more undertaken by means of the spoon, but they are pressed out by stroking the eyelid.

In many cases the blame of the bad healing of the wound was ascribed to the flap section. As to this, confirmatory examinations have been carried on by Gräfe for a number of years. He attempted first to separate a class of cases, in which he did the simple linear extraction, and these were the cases in which the cataract was soft or fluid. The operation consisted in this, that with a pupil as widely as possible dilated, an incision was made with an angular lance-shaped knife, of a length of from 2½ to 3 lines; and then entering the wound with a small hook or a needle, the capsule was opened. Pressure was exerted while the opening was made a gaping one, and thus the lens pressed out. The results were, however, not so favorable as had at first been expected. Parts or remains of the lens often remained behind on the periphery, the pupil contracted, the iris prolapsed, and we were obliged to cut it off.

Professor Arlt then said he must make a little digression as to iridectomy. This was, first of all, a method practised in the Vienna school; it was, however, practised by Von Gräfe with entirely another purpose than by us, namely, in order to limit the advance of the chronic inflammation of the iris and choroid, and to cause the inflammatory process to recede. A change in the operation was found to be necessary, so that we were not satisfied with making an opening in the iris, but great weight was laid upon the attempt to cut out the iris broadly from the pupillary to the ciliary border, in order to obtain a wide opening. In 1857 Gräfe conceived the idea of doing iridectomy in glaucoma. The expectations which this operation excited were realized in a brilliant manner; thousands of eyes since then have been saved, which otherwise would have been lost. This method of treatment stands in substantial relation to further progress in respect to the extraction of cataract. In 1859 Gräfe published an article on linear extraction combined with iridectomy. He used as before a lance-shaped knife, only the incision was not made in the middle of the cornea, but on its border, and generally on the temporal side. The iris was then cut out as far back as its periphery, the capsule opened, and the lens brought out by pressure. By this method we could extract every cataract which was not fluid, but which had a hard nucleus. A spoon was employed in this method, which was different from Daviel's, in that it was broader and somewhat turned up. Gräfe confined this method to cataracts with a soft lens substance. Dr. *Waldau*, his assistant, went a step further. He constructed a peculiar spoon of his own, to bring out the lens, and asserted that in future the flap extraction could be entirely avoided if such a spoon were introduced behind the lens. The incision was made quite peripherical, the iris excised, the anterior capsule slit open, and then the spoon was introduced on the cortical substance, and the lens in this manner drawn out. Dr. Arlt said he never had had any faith in this method, because we have not a sufficiently large wound in order to draw out the lens; and, added to this objection, a spoon must be introduced which has quite prominent edges. This method was soon given up. The proposal of *Mooren* in Düsseldorf, which really proceeds from Gräfe's proposition, to make an iridectomy six weeks before making the flap section, obtained no favor, since it is not pleasant to operate twice on a patient, allowing him to wait so long between the operations. But this method has been partially accepted, in uniting iridectomy with the flap section. But in this method also we often have closure of the pupil, and occasionally we lose an eye. Jacobson, in Königsberg, has proposed the flap extraction combined with iridectomy, performed with the patient under chloroform, and in a hundred and some cases has only lost one eye.

Dr. Arlt had not fully agreed to this method of procedure, because in general he was not willing to anæsthetize a patient, when it is not quite necessary. He had never found in the disquiet of the patient any hindrance.

He allowed the patient to lie down during the operation; and then all morbid tension on the part of the patient disappears, the lids are held simply with the fingers, and the operator secures himself against the movement of the globe by forceps, with which the conjunctiva is seized a little way from the cornea.

The methods of Gräfe and Waldau were not much modified by Crichett (of London). He took an angular lance-shaped knife, used an elevator to hold the lids open, and then the knife is thrust into the border of the cornea, and an incision of three to four lines long made, which could be widened on each side by a pair of curved scissors. Then he cuts out a piece of the iris, opens the anterior capsule as far as the equator, and introduces his spoon, which differs from that of Daviel, in that it has no edges, but a slightly convex surface, which projects anteriorly. Arlt had done this operation three times, but returned more willingly to Beer's flap extraction. Often much of the lens substance remains behind; we may burst open the posterior capsule before we have the remains of the lens all out; these latter left behind, may get into the vitreous humor and cause a reaction from this. Thus stood matters in 1864. Gräfe proceeded from the view that the most eyes were lost by the bad healing of the corneal wounds. The flap extraction had the advantage that the lens could be easily brought out, even without any contusion of the pupil, because the wound corresponds fully to the diameter of the body which is to come out; but just here there is a disadvantage in reference to the healing, since the wound readily opens. Gräfe proposed, therefore, to make a purely linear incision. He makes this with a knife, which is about one line broad, on the upper border of the cornea, carries it through posteriorly, makes the counter puncture at a sufficient distance, and turns the knife, so that its back is directed towards the imaginary middle point of the cornea. The incision is ended by the withdrawal of the knife. This operation is done while the patient lies in bed, and the lids have been kept open by an elevator. The section is within the limits of the cornea or the *limbus conjunctivalis*. If hæmorrhage occurs, this should be checked. After this the operator, having fastened the globe, enters the eye with the forceps, seizes the iris, which sometimes prolapses of itself, and this is cut off by an assistant. Then

the capsule is opened up to the equator; and then with the globe still fixed a spoon-shaped instrument is laid on (angesetzt) it, pressure exerted, and the lens in this way comes out without being bruised. This is the method as Gräfe now recommends it. Formerly he advised, besides, to go behind the lens with a little bent hook, and to draw it out. This is, however, a somewhat hazardous procedure. Later he recommended for the withdrawel of the lens a spoon, but this had very sharp edges, and could easily scratch the lens. In the report which he gave in the fall of 1865, it appeared that he had operated on sixty-nine cases, in which he had not lost a single eye, and only seven ended with imperfect result. Arlt could not, however, decide as yet to operate by this method. On the 9th of March, 1866, Gräfe wrote to Arlt, that he could now, after having operated on 200 cases, say positively that he would never again do a flap extraction. Arlt promised towards the end of the session to refer further to the results of this operation, which he now practised a great deal. Only this much could he now say, that this method promises to accomplish all that Gräfe declares for it. Prof. Arlt demonstrated the method on two eyes, which he had brought with him.—*Wiener Medizinische Presse, May* 6th, 1866.

Dr. Williams, of Boston, has applied sutures to the corneal wound, after flap extraction, by means of very minute needles, for the purpose of assisting the healing, which Gräfe declares a great obstacle to the success of this operation. Thus far the procedure has been attended with gratifying success.

Capsicum in Delirium Tremens.—Dr. Lyons (*Dublin Medical Press and Circular*) has been employing with success capsicum in delirium tremens. He urges the importance of recognising the early stages of the disease in order that the remedy may then be administered. He observes that a brief but variable period often precedes the fully developed attack of delirium tremens, especially in first cases, in which the patient presents anomalous symptoms unintelligible to himself, and not always read aright by his attendant. This stage is in some patients marked by the occurrence of tremor, sleeplessness, and general distress and anxiety, without a trace of delirium. In other instances slight illusions prevail, without tremor, from which the patient can by an effort arouse himself, and under strong self-directed exertion of the will even command his faculties for a time, and pursue avocations of business, to break down, it may be hopelessly, a few hours subsequently, if his condition is neglected, misunderstood, or mistreated. He further remarks that under these circumstances the treatment by capsicum comes in very opportunely, and by its employment the disease may be cut short, and so save the patient from the consequences of his imprudence, and possibly restore him to a reformed life. He has found that a single dose of 20 grains in a bolus is usually sufficient, although in some individuals of extremely intemperate habits it was found necessary to repeat the dose some three or four times. This remedy has been of service when opium has failed, in procuring the patient a profound and refreshing sleep for ten or twelve hours at a time. Dr. Lyons's explanation of the physiological action of the remedy is that it produces a powerful stimulant and sedative influence by its direct action on the gastric filaments of the vagi.

Chlorate of Quinia.—This newly discovered salt, which the profession owes to Dr. Lyons, continues to be employed in his clinique and in his private practice with good results. Its use is indicated in cases of scarlatina, typhus fever in low pyrexial states, local inflammations, etc. Its good effects may be traced to the large amount of available oxygen which it contains, and the valuable tonic alkaloid which forms the base of the salt. Dr. L. suggests that it will doubtless prove of great value in gangrenous stomatitis.—*Dublin Medical Press and Circular.*

Report on Spurious Vaccination.—Dr. S. E. Habersham, late surgeon in the Provisional Army of the Confederate States. in a very interesting communication to the Southern Medical and Surgical Journal, comes to the following very sensible conclusions in reference to the nature of spurious vaccination—"That the disease is pustular at its first appearance; that it resembles ecthyma in its general character; that it is but a local manifestation of a general disorder, or vitiated condition of the blood; that this vitiated condition resulted from improper and spare diet, together with inattention to cleanliness, thus impairing the eliminating functions of the skin; that syphilitic virus has had no influence in producing the disease; that the morbid effects have in most of the cases resulted from a deficiency in condition independent of any imperfection in the vaccine virus; that the disease can only be removed by those means calculated to improve the general condition and restore the healthy play of all the functions."

Necrosis of Lower Jaw produced by the Oil of Tobacco in the Hollow of a Decayed Tooth.—A case has recently occurred to Mr. Paget (Lancet) in which death of a portion of the bone of the lower jaw was occasioned by the introduction of the oil of tobacco into the cavity of a carious tooth, for the purpose of curing the toothache. The patient was an Italian sailor who used the oil from the stem of his pipe. Mr. Paget, in remarking upon the case after having removed several sequestra, said:—"The case well illustrates a source of danger which is not generally recognised. The practice of smoking is very widely spread, and foul pipes and carious teeth are very common. Every smoker of a pipe has been disgusted now and then by sucking into his mouth a few drops of the highly pungent and nauseous product of the combustion of tobacco. In the action of smoking the tip of the tongue ordinarily receives this deleterious fluid, and is very much blistered in consequence. Were it not for the tongue one can readily imagine that hollow teeth would often receive this fluid; with what amount of risk the case before us well shows. It is well known that, for phosphorus to excite the inflammatory action which so often affects the lucifer-match workers, the fumes must be applied to a raw vascular surface in immediate connexion with the nutrition of bone. This almost always happens through the medium of a carious tooth. There is no reason to suppose that tobacco oil would set up inflammation except under similar circumstances. It is, however, very probable that some cases of acute necrosis of the lower jaw of obscure origin may have really originated from the accidental poisoning of the tooth-pulp by this liquid, and the possibility of this source of disease should be borne in mind."

Preservation of Meat.—A preparation of paraffin devoid of smell and taste has been made, which, it is said, will preserve meat for an indefinite time.—*Dublin Medical Press and Circular.*

Theine Dye.—A new dye, which promises to be of much commercial value, has just been procured from theine, the principle of tea. If theine were only procurable from tea, the new discovery would not be of much importance, but inasmuch as the principle exists largely in other plants, it will prove of considerable importance.

THE MEDICAL RECORD.

A Semi-Monthly Journal of Medicine and Surgery.

CLINICAL INSTRUCTION.

THE high rank which clinical education now holds in the regular medical course is so well conceded, that there is hardly a medical college in the country that omits to state in its announcement that this branch of teaching will be well attended to. There is, in fact, nothing connected with medical education concerning which a more uniform opinion is held than the importance of combining clinical and didactic teaching. The manner, however, in which such instruction is now carried on, even in connexion with our large metropolitan schools, is not by any means what it should be. There is evident in this branch that same want of systematic arrangement that we have noticed in the other departments of study.

In the first place, the study is not an acknowledged part of the education in our colleges; it is merely optional with the student whether he will avail himself of such means as may be thrown in his way or not, the presumption being on the part of the professors that he will not allow golden opportunities to slip by unheeded. That this is an altogether erroneous view must even be admitted by the teachers themselves, when they notice the small number in attendance upon the clinics, and the still smaller proportion who frequent the wards of the hospital.

Students in this country are notoriously wanting in the clinical appreciation of disease; and we have only ourselves to blame when we are called upon to receive the criticisms of our more prudent and exacting brethren on the other side of the water. We cannot excuse ourselves on the score of deficiency in clinical advantages, for as a whole this country, with her vast medical resources, will compare favorably with any other. Our hospitals are large and well appointed, our surgery in the main is very much better than theirs, and our diseases are, for variety, to say the least, remarkable.

For all that, our students are graduated by scores and hundreds from our colleges without having at all appreciated the important difference which exists between the theory and practice of their art.

The professors are in no small degree responsible for this, by the apparent unconcern they themselves exhibit in reference to the enforcement of certain regulations for bedside study, which shall apply to all those under their charge. Hospital instruction should be as much a part of the course of every student of medicine as any other of the acknowledged branches, and his skill in the observation of disease should be as thoroughly tested by appropriate and stated examinations at the bedside as by any similar tests in the lecture-room.

So-called "classes in diagnosis" have been formed privately by several of our most skilful teachers in the different branches of medicine, and their success has been gratifying enough to have their plans adopted on a larger scale. The great objection to this system has been that the class of a medical college would be too large to question each individual and give him an opportunity for making his own diagnosis in a given case. But this objection could be overcome with ease by dividing up any medical class into sections that should have stated days for meeting. If on any particular day an important or rare operation is to be performed, or a unique case exhibited, it would be easy to give a general invitation to all who might wish to witness it.

The arrangement between most of our medical colleges and hospitals is such, that a sufficient complement of the professors of each of the former are members of the attending staff of the latter, each teacher being thus enabled, if so disposed, to take care of his own class in his own branch. Students need not confine themselves to one particular teacher, but they could, during those intervals of time which take place between the meetings of their respective sections, enjoy the instruction of others of the attending staff who may or may not be connected with a college.

The student should be compelled to attend the hospital regularly, otherwise he will be apt to neglect it for studies which he at the time may believe to be more important. The way, in our opinion, to make it compulsory, and consequently beneficial, is to exact the attendance of every third-course student, and insist upon his being a member of one of each of the sections of medicine and surgery. As for the first and second-course student, attendance might be a matter of choice, so long as it did not interfere with his other studies.

The practice of allowing third-course students to attend obstetric cases is one which cannot be too highly commended; and it is to be hoped that many of our colleges that have not already done so, will follow the good example set them by the senior institutions. We are however sorry to see that it is not more universal, and that even this is left to the choice of the student as to whether he will attend such cases or not.

The poly-clinics are of great value in illustrating the different lectures of the professors, and we are glad to

see that they are now so much a recognised part of the college curriculum, that regular days in the week are set apart for them. The introduction of the practical study of special branches in connexion with these clinics is a very important advance, and one which, under proper regulations and restrictions, must be of great benefit to the student and the institution. Excellent as most of these clinics are, they could be much more beneficial to the student if "diagnosis classes" were formed in connexion with them, such classes being made up entirely of third-course students.

The time has come when more attention must be paid to a thorough and systematic clinical course of instruction; it is what the student specially needs, and what the profession will demand of those who occupy professorial chairs or hospital appointments. We think ourselves warranted in saying in this connexion that those medical schools that will undertake to make this study absolutely compulsory, will not only gain increased patronage, but will add more value to their diplomas.

THE remarks of Prof POST upon the subject of Quarantine, made in our last issue, call from us a somewhat further explanation of our views as expressed in the editorial referred to by him.

In our number of May 15th, in commenting on the action of the "American Medical Association," in regard to quarantine and cholera, we expressed our regret as well as surprise at the course pursued by those gentlemen who voted to lay the whole subject on the table, and thus give the matter the go-by, when the whole country, and Congress especially, were anxiously looking to the convention, composed as it was of the ablest members of the profession from all parts of the United States, for some expression of opinion on the subject. It was, we thought, not a manly course for such a body to take under the circumstances, and on this point we have seen no occasion to change our opinion. Further reflection satisfies us, however, that the question of *contagion*, or *non-contagion*, was not fairly tested, and that no valid conclusion can be drawn from the final vote, in regard to the opinions of the members on these points. A vote to lay on the table can hardly be considered as testing the true merits of any question. In the present case, as is well known, a variety of other considerations had more or less influence.

We therefore, perhaps, went too far in considering those who voted in the affirmative as non-contagionists, for we have since ascertained that many of them were not so. There can be no question, we think, that nine-tenths of those who composed the convention believed in the portability of cholera by *persons and their effects*—in other words, in its *infectious character;* and if time had been given for a fair and full discussion, there can be no doubt that an immense majority of the members would have voted to petition Congress to establish a general and uniform system of quarantine at all our ports. This, we think, is obvious from the fact that nearly all to whom the paper was presented the next day on board the boat to Annapolis, requesting a meeting in Baltimore that evening for this very object, signed the call. So far, therefore, as we may seem to have reflected on the motives of those who voted to lay the matter on the table, we are ready to admit we may have done them injustice; while at the same time we must continue to regret that such an abortive effort crowned the closing efforts of the convention.

Reports of Hospitals.

PENNSYLVANIA HOSPITAL.

SERVICE OF DR. J. M. DA COSTA.

[From our own Reporter.]

ACUTE BRIGHT'S DISEASE—URÆMIA SUPERVENING—DEATH—AUTOPSY.

APRIL 18, 1866.

THE patient, Arthur D——n, æt. 26, was admitted on the evening of the 16th, less than two days previously, and being too ill to be brought into the amphitheatre, the examination of the case was made before the class, at the bedside of the partially unconscious patient.

His mind had been so dull since his admission that it was with very great difficulty a history of his previous condition could be gathered. Four weeks ago, it seems, he attended a fire, from which he returned very wet, and slept in his clothes. He got up with a pain in his back, in the region of the kidneys, which pain lasted four days, during which time he passed less urine than usual. Afterwards he felt well again, and noticed nothing abnormal until two days before his admission, when there came on a sudden swelling of the abdomen and an increased secretion of urine, unaccompanied by marked fever, swelling of the feet, or any other symptom of dropsy. Since three days his feet are swollen, and he sought admission on account of the dropsy.

Shortly after admission his urine was found to contain a considerable quantity of blood. But examined subsequently under the microscope twice, no blood globules were discovered, and but one cast. The urine was very highly colored. There was a considerable amount of albumen, one-half of a test tube remaining full of the coagulated albumen after the application of the usual tests of heat and nitric acid.

Leaving out the history of the case, which is not very satisfactory, the symptoms indicate the case to be one of *acute Bright's disease.*

Since an early hour this morning (18th inst.) the man has been in a dull, stupid condition; he breathes noisily, respiration being at times quite stertorous; he is almost unconscious; the pupils are dilated, and do not react readily.

Percussion over the anterior portion of the chest is clear; posteriorly he cannot be examined on account of his position in bed, except at the posterior portion of the right lung, where the resonance on percussion is somewhat impaired.

Respiration is vesicular, though feeble; but as the breathing is very irregular, much stress cannot be laid upon this impairment. The number of respirations is twenty to the minute. These results, as far as they go, would show nothing abnormal about the lungs.

The heart gives a faint systolic murmur at the base, but otherwise presents nothing abnormal, if we except that the first sound at the apex is unusually dull, and apparently much more so over the left than over the right ventricle.

There is considerable distension of the abdomen, yet this is far from being all due to ascites, for there is a great deal of flatulence with it. The fluctuation is very much obscured, being only slight and over the lower portion of the abdomen, and is obscured for the most part by the collection of air within the bowels.

It is impossible to ascertain the amount of pain over the kidneys, since the patient's stupor and restlessness are such that his statements would not be reliable. Until three o'clock yesterday afternoon he had passed water freely. Since that time it has had to be drawn off with the catheter, but it has not diminished in quantity, and is very much discolored.

The lower limbs are only slightly œdematous, pitting somewhat on pressure along the legs, but not on the thighs. There is no œdema of the hands. There is a visible fulness of the veins of the neck, with distinct pulsation there, more perceptible on the right side than on the left. The pulse is 96, and rather full. The breath does not discolor a slide on which muriatic acid has been placed.

The patient had taken some medicine before entering the hospital, and the bowels were freely opened three or four times yesterday, since which time they have not been moved.

He has had some sickness of the stomach, having vomited once yesterday morning and twice yesterday afternoon. The patient obstinately clinching his teeth, makes it difficult to examine his tongue. The skin is hot, inclined to be moist in parts, but not sweaty. An attempt to look at the tongue produced a struggle eventuating in the production of epistaxis, and the tongue was found slightly covered with a yellowish coat, except at the tip and edges, where it was clean. The reflex movements are good, as evinced by tickling the soles of the feet; but though sensibility exists, it is somewhat impaired. There is no paralysis of motion; great stupor and restlessness being the most marked cerebral symptoms.

The history of the case shows an acute attack coming on after exposure, attended with frequent micturition; that condition beginning to disappear, swelling of the feet setting in three or four days ago with ascites, and without marked swelling of the face. This attack apparently did not give rise to any very great disturbance. The man was brought to the hospital in a carriage; felt very weak; complained of oppression in breathing without suffering pain; and his mind, though dull, was sufficiently clear to have given the resident physicians all the information about his condition. In this state he remained until after midnight, when the present symptoms developed themselves. Yesterday afternoon and last evening Dover's powder was given by the resident, for diaphoretic purposes; otherwise his treatment consisted in nourishment and a very small amount of stimulus—milk punch, without any local treatment.

Examined this morning, we find this rapidly developed coma; dilated sluggish pupils; sickness at stomach; retention of urine; vomiting; preserved motor power; slightly modified sensibility; active reflex movements; noisy, irregular breathing; absence of any pulmonary symptoms; and the effect of a disturbed action of the heart, as manifested by a slight systolic murmur.

This, then, is a typical case of *acute Bright's disease*, commencing with a clear history of cold after exposure, attended with fever, prostration, accompanied by some pain in the back, and by albuminous urine of rather high (1020) specific gravity. Now everything has changed. Is this the result of acute Bright's disease? Is this the ordinary progress of such a case? By no means. An accident has happened to this patient to which every case of Bright's disease, acute or chronic, is always liable, and which may prove fatal, as will most likely be the result in the case under consideration. This accident is the *supervention of poisoning by retained urea*. This is a case of uræmia. It is not quite hopeless. Cases of uræmic poisoning do recover; but taking the history of the present case, we can but view it in a gloomy light, and the prognosis is doubtful and unfavorable. Coma is very marked, with dilated sluggish pupils; there is vomiting, without any special reason for that vomiting. Coma rapidly developed, not following any fever, not occurring in the course of any disease where there may be reason to expect such a condition, is always a very grave indication, and in the majority of instances points to the kidneys as the seat of disease. Indeed you would never be doing your patient justice, unless in every case of rapidly developed coma, an examination of the urine be made, to see if the condition be not dependent upon a disease of the kidneys.

The pupils are sluggish and dilated. So much importance would not be attached to this point were it not for something which had preceded it in the treatment of the case. The resident, finding the patient restless, noticing that the skin was dry, thought a diaphoretic would be of advantage, and in the interval of the visits administered Dover's powder. Are not these symptoms, therefore, the result of the administration of opium? the more, that in all cases of Bright's disease there is a peculiar susceptibility to the effects of opium. Might not the sickness at the stomach, too, be due to the ipecacuanha taken? We do not answer in the affirmative. The state of the pupil is not that which would follow the exhibition of opium, for it would then be contracted; and the sickness at stomach and vomiting were more marked before the administration of the Dover's powder.

Not long ago Dr. Da Costa had in charge a case of abscess of the kidney, which during life was watched with a great deal of interest. Sudden vomiting set in, accompanied by some disturbances of respiration. After watching the case for a day, he made up his mind that it was a case of uræmia. The sequel proved that this view had been correct. The man died of marked uræmic poisoning. Vomiting occurring without any obvious cause, and often joined with a clean tongue, where there is no reason to suspect gastric disturbance, ought in every case to direct attention to the kidney, for it is often a sign of uræmic disturbance.

In cases of uræmia, such as this, accompanying Bright's disease, there may be retention of urine—there may be suppression of urine. The common belief is, that when you have these grave nervous symptoms arising, there must be necessarily no urine voided. This is true in many cases. Often you will find the amount sensibly diminished, and then the dulness of mind, coma, and other symptoms arise. But it is not always the case. In a practical point of view, you will sometimes find apparently the quantity of urine continues the same, but a close chemical analysis will show a very different state of things. Some ingredients will be notably diminished; urea absent in the urine, and the amount of albumen sensibly diminished, as it is remarkably so in the present case. The specific gravity of the urine drawn from this man this morning is only 1014, whereas yesterday it was 1020 before the uræmic

symptoms occurred, showing a larger amount of solids in the urine.

Thus the mere quantity of urine is no proof against the non-occurrence of uræmic poisoning, or that the urinary constituents are not retained; for the most important may be retained, and yet the amount of water be the same. Here we have the urea retained in the blood, with possibly the tubes clogged with albumen, and perhaps not allowing all the albumen to pass through; and retained in the system, the urea acts as a poison on the nervous system. Physiologists are at variance as to how it acts. Some maintain that it acts only by virtue of its decomposition; it is converted in the blood into carbonate of ammonia, and the patient is in reality poisoned by ammonia circulating in the blood. This is the opinion of *Frerichs*, who has done much to investigate this subject. In proof of this view he adduces the fact that often, if you will take a glass slide dipped in muriatic acid and place it before the mouth of the patient, it will become coated with a white deposit, which are crystals of the chloride of ammonium or muriate of ammonia. In the present case this experiment was negative—there was no chemical reaction. Other physiologists inject urea into the blood of dogs, and find poisonous results follow, where there could have been no reasonable supposition of decomposition. Thus partly on clinical grounds (which this case favors), partly in accordance with the physiological experiments on animals, we must admit that the opinion of Frerichs, that the urea must undergo decomposition, is too absolutely stated. It may occur in some cases, but it is not necessary for the production of uræmic symptoms.

What can we do for our patient to bring about again a healthy state of blood, lessen the coma, and cause the kidneys to secrete again as they should secrete? In the first place, derivatives are of immense advantage. In this connexion Dr. Da Costa recalls a distressing case of repeated uræmic poisoning attending Bright's disease, in which there were six or eight distinct attacks of uræmia intercurrent with the Bright's disease. The most marked amelioration was produced by free purgation; dulness, vomiting, dilatation of pupils, would often cease as a free action from the bowels was obtained. Hence, in every case, resort to purgation. An attempt was made to give the present patient two drachms of the compound jalap powder, but he could not swallow it, and it could not be introduced between his clenched teeth. Two drachms of the tincture of jalap were administered by injection, but had not yet operated. He will be given a large enema of castor oil with vinegar, mixed up with gum or egg, into an emulsion with warm water, so as to produce a free purgative action. Vinegar in the treatment of tympanites, as in typhoid fever and other diseases, has been found to yield speedy and highly beneficial results. Turpentine would be inadmissible on account of the state of the kidney. We want to act on the blood, to keep the urea in such condition that it will not be decomposed; we shall therefore, without even fully accepting Frerichs' views, endeavor to keep it from decomposing, because we know that such decomposition is possible, or counteract this decomposition should it have taken place. Therefore we must act on the blood and act on the kidneys. To act on the blood, the mineral acids will be found very valuable, and sulphuric acid is found of signal use in uræmia; so also are muriatic acid and nitro-muriatic acid; but Dr. Da Costa prefers benzoic acid, which, moreover, will have the advantage of being a diuretic to remove the clogging of the tubes with albumen, which is probably the mechanical cause of all the disturbance causing the urea to be retained. He would order the following mixture:—Benzoic acid, grs. xv.; biborate of soda, grs. x.; sweet spirits of nitre, f 3 j; simple syrup, f 3 j. If the stomach should not bear this mixture, the amount of benzoic acid will be diminished. A dessert-spoonful of this mixture is to be given in water every second hour, for the present. Benzoic acid is a diuretic, causing, moreover, as we well know from experiment, an excretion of urea—just what is wanted in these cases; it is an acid to a certain extent, which is also required; the borax is given for pharmaceutical purposes, because it causes the benzoic acid to be much more soluble.

Nitre is a diuretic, and acts, moreover, decidedly on the skin, and this can be favored by applying heat around the man; bathing him frequently with hot vinegar and water, to obtain free action from the skin. And acting on the skin and bowels, will relieve the kidney to some extent, and cause the urea to be thrown out elsewhere. Should the patient convalesce sufficiently to ask for drink, he will be given a lemonade.

The history of this instructive case, subsequent to the clinical remarks reported above, is substantially as follows:—In addition to the above treatment he was ordered to be wet cupped over the kidneys, to the amount of four ounces of blood, and then dry cups were applied over kidneys and back of neck.

Morning of the 19th.—Breathing less sonorous; pupils still dilated; continues very restless, especially when disturbed; pulse 82, and less full than yesterday, but of good volume; belly remains tympanitic; no urine has been discharged since 11 P.M. of 18th; at 9 A.M. a few ounces of urine were drawn off by catheter, the patient struggling so violently as to require his being held by several attendants. The veins are still much distended. The patient had not taken all the medicine ordered yesterday, his teeth being so firmly clenched as to render it requisite to separate them by the levers of a strong forceps constructed for the purpose; and then as he spit out all that was forced into his mouth, the stomach tube was introduced, which produced vomiting; and as soon as this subsided, about three tablespoonfuls of the mixture containing acid. benzoici, grs. xv.; sodæ biboratis, grs. x.; and spts. æth. nitrici, f 3 j. to the f ℥ j. were thrown into the stomach, but were instantly rejected by vomiting, so that but a small portion could have remained in the stomach. After this the medicine was administered occasionally at periods when he would be found breathing with the mouth open, so that he probably retained in the system thirty grains of about ninety grains of benzoic acid that were administered. Frequent vomiting prevented the administration of much nourishment. A hot vapor bath had been applied the day before, requiring several persons to hold him in bed at the time. The bath produced profuse perspiration, but only for a very short time. The first stool since the several injections was passed this morning, and was of a light clayish color. The sponging yesterday with hot water and vinegar was repeated three times, but without any appreciable effect. He was ordered to-day four ozs. beef essence, with one egg, by injection, every two hours; blood to the amount of six ozs. to be taken by cups from the back of the neck; the sponging with hot water and vinegar to be continued.

20th.—Restlessness more intense than ever; has had no stimulus since day after admission; skin dryish, does not exhale any peculiar odor; pulse 120, compressible, and smaller than yesterday; breathing less noisy and more through the mouth, though still a rather high-pitched stertor. No passage from bowels since yesterday morning; has passed no urine since 11 P.M. yesterday, when about three ounces were drawn off by the catheter. Although the legs permit flexion, the pa-

tient generally lies with them extended, and the gastrocnemii contracted. Muscular movements have a spasmodic character without any distinct convulsion; the lips and teeth are covered with sordes; tongue dry and damp. The arms, when raised, do not fall upon the bed, but come down slowly and gradually: does not respond in movement to poking with the finger as much as yesterday; remains perfectly unconscious, with pupils dilated and insensible to light. Injections of vinegar and water to relieve flatus were given, but came away directly, as also did the enemas of beef-tea and egg. A small quantity of nourishment and medicine was given by mouth, and retained.

In the afternoon there were three passages from the bowels, thin, yellowish, and small in quantity. Urine was drawn off this morning, still less in quantity, lighter colored, and of a lower specific gravity; acid reaction albuminous, but less so in quantity than heretofore. The treatment was continued, and the medicine and nourishment were administered as well as could be at short intervals. At 11 P.M. urine drawn off by catheter, not more than two ounces; the bladder as before, firmly contracted.

21st.—Patient died at 12·30 P.M. During the last twelve hours of life he took at least twenty ounces of beef essence, and eight ounces of the mixture containing 240 grains of benzoic acid and two ounces of sweet spirits of nitre. During this time he did not vomit at all, and had two alvine evacuations. His skin was dry and rather hot, except immediately after the vapor bath, when there was a slight tendency to perspiration. The tongue remained covered with a black coat. The restlessness became less marked, though quite as marked when the patient was touched.

During the whole period of his unconsciousness the chief muscular movements were raising the arms up over the head, tossing of the body from side to side, and the constant contraction of the gastrocnemii. The pupils remained rather dilated, and almost immovable. Vomiting ceased about eighteen hours before death.

The urine examined on the evening of the 17th was rather less than normal in quantity; of a blood-red color—very cloudy; giving a heavy deposit upon standing. Sp. gr. 1022; acid, not phosphatic, abundant in chlorides; very albuminous, the tests showing a given quantity to contain half the quantity in bulk of deposited albumen. Examined on the evening of the 18th, the urine was about the same in color and consistence; sp. gr. 1020; acid, not phosphatic, abounding in chlorides; less albuminous. On morning of 19th the urine was lighter in color, and less cloudy; sp. gr. 1014; acid, not phosphatic, abounding in chlorides; still less albuminous. The whole amount of urine passed from 9 A.M. of the 19th to 11 A.M. of the 20th was kept and examined. The total amount was 280 cubic centimetres; sp. gr. 1013; acid, not p' osphatic; chlorides abundant; albumen very slight in quantity. An ounce of this was taken and tested for urea, being first evaporated, and then treated with nitric acid; then dried and weighed. The result was, that in 280 cubic centimetres, or nine fluid ounces of urine passed in twenty-four hours, there were but 34·56 grains of urea in place of 286 grains, given as one of the lowest estimates of the average amount excreted in twenty-four hours by a healthy man.

At 8·30 P.M. of the 19th, the temperature of the body was 99°; pulse 98; respiration 22.

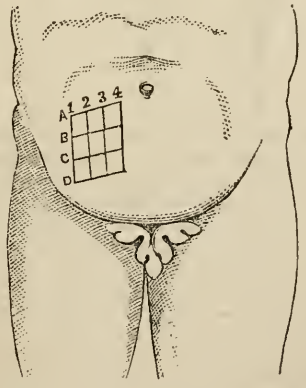
AUTOPSY, *eight hours after death.*—The general external appearance presented no peculiarity except a somewhat distended abdomen. Thorax contained no effusion; adhesions on right side, but not firm; no adhesions on left side; both lungs healthy, except being heavily congested posteriorly. No effusion into pericardium; right ventricle dilated, walls one-fourth inch in thickness; left ventricle hypertrophied, the walls seven-eighths of an inch in thickness; the cavity not altered in size; valves healthy. Abdomen distended. Stomach and intestines distended with flatus, and of healthy appearance. Liver normal in size, and a perfect specimen of a hob-nail liver; left lobe somewhat large; no biliary calculi. Kidneys larger than normal, and pale. Bladder slightly contracted. Spleen rather larger than natural, though healthy. The cavity of the abdomen contained about two quarts of serum. The peritoneum presented a healthy appearance. The veins of the omentum were congested. On cutting into the kidneys they presented a typical specimen of the earlier stages of Bright's disease. The cortical substance was much enlarged, and encroached upon the tubular portion.

New Instruments.

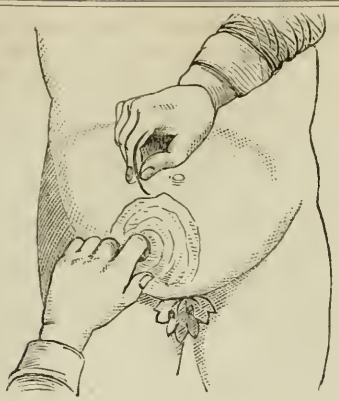
PROFESSOR DOWELL'S SUBCUTANEOUS SUTURE FOR THE RADICAL CURE OF HERNIA.

PROFESSOR GREENVILLE DOWELL, of Galveston, Texas, has kindly furnished us with the following description of the new instrument which he has devised for the radical treatment of hernia, and the manner of using it.

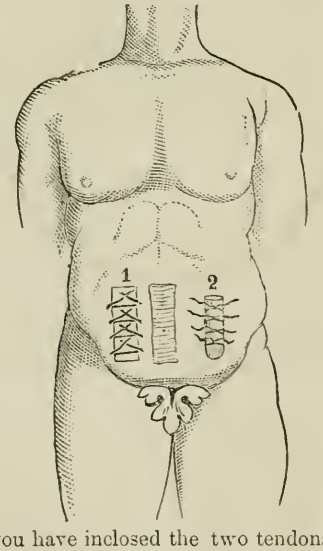
"With a double spear-pointed needle (as represented in the cut) threaded with silver wire, the two sides of the rupture are pulled together, thus restoring the natural parts.



"The operation is performed in the following way. First, four lines are drawn across the rupture; the needle, threaded with silver wire at one end, is taken hold of by the threaded end, and at the second line of the right side, inserting the point after lifting up the cellular tissue and passing the needle out on the fourth line, it is drawn nearly through. At this stage seize the other end of the needle and reverse the point, passing it through the left tendons of the oblique muscles; your left index finger invaginating the sac and acting



as a guide to the point of the needle. Under this finger the needle is passed to the tendons of the right oblique muscles, inclosing about one half-inch; then the point is brought out on the first line. Then seize the other point and pull it through until the other end of the needle is *above* the tendons in the cellular tissue. Now reverse the point, lifting or pinching up the skin and cellular tissue as at the commencement, bringing out the needle in the third line.



"Thus you have inclosed the two tendons in a loop, and the two external ends cross over the rupture. Now close the opening by pulling the ends of the wires together, as a shoemaker does when he sews the soles of shoes. Tie these over a piece of cork and let them be tightened from day to day until the wires become loose, after which they should be taken out.

"I have performed this operation once with entire success, and the cure was perfect; the patient at the end of five years remaining perfectly well. I tried to pass the wires with a common surgical needle in two other cases, but could not put them through in the manner desired, and they were failures or partial failures. Messrs. George Tiemann & Co. made me some needles with an eye in the centre, but they were too short, so that I could only use them on children—and the one cured was a child. In performing this operation, and in using the needle, care should be taken not to puncture the intestine, nor take up the omentum, nor to allow the cellular tissue to be between the loops of the ligature, else you will have a plug formed and filling up the space that should be closed."

Correspondence.

INJECTIONS IN CHOLERA.

To the Editor of the Medical Record.

Sir—In the fifth number of the Medical Record my attention was attracted to an article by Dr. O. H. Smith of this city, entitled "Injections in Cholera." In the perusal of it, I was so impressed with the straightforward earnestness of the writer, the simplicity and reasonableness of his method, and the positive manner in which he asserted the power of stimulating injections to control the discharges in cholera, that I called on the doctor soon after for some of the particulars of the experience on which he based his assertions.

In addition to an extended relation of cases in which his plan had proved efficacious during the cholera epidemic of 1854, Dr. S. showed me letters from Dr. Waltzer (Deputy Health Officer at Quarantine), who had, at Dr. Smith's request, used the stimulating injections in several extreme cases of Asiatic cholera. In these letters Dr. Waltzer distinctly states that they had controlled the discharges in every instance. My own experience in the treatment of cholera during three epidemics—two in this city, and one in Central America—convinced me that if the plan above alluded to succeeded in other hands as it appeared to have done in those of Drs. Smith and Waltzer, it was a great improvement in the treatment of the disease over any method within my knowledge, and I determined to test its efficiency at the first opportunity.

This occurred on the 19th of the present month, when at 7 P.M., I was called to see Mr. W., a merchant, aged about 40, residing in one of the most unexceptionable localities on Murray Hill. Mr. W., who had enjoyed uninterrupted health for a long time previous, returned the evening before from a fishing excursion in Orange county, and had partaken freely of strawberries and trout for his supper. On the following morning he was not feeling as well as usual, but went to his place of business; he returned at 11 o'clock A.M., feeling much exhausted, and suffering with diarrhœa and nausea. In the course of an hour or two, vomiting of a thin, light-colored fluid took place, accompanied by discharges from the bowels, which latter, painless though not very copious, were apparently of the same character, and occurred at intervals varying from half an hour to an hour. This condition of affairs continued without any sort of treatment until my arrival at 7 P.M., when I found him with a countenance pale and anxious; skin hot and dry; tongue dry, rough, and slightly furred; pulse small and quick—108; respiration accelerated, with frequent sighing; great restlessness; a craving thirst and distressing nausea, with a constant desire to have a passage from his bowels, which he struggled manfully to control. Within five minutes after my arrival he had a copious alvine discharge of a whey-like fluid, with vomiting not unlike the same. I at once had a large sinapism applied over the surface of the stomach and bowels, and administered a tablespoonful of the following mixture:

℞. Spts. ammon. aromat.,
Tr. camphoræ,
" opii,
" capsici,
Chloroformi, āā ʒ i
Aq. cinnamomi, ʒ iiss. M.

Lumps of ice were allowed, to be slowly dissolved in the mouth, to allay thirst. For a little time after the administration of the medicine the patient seemed quieter and expressed a sense of relief; but it was of short

duration. After half an hour, vomiting and purging recommenced, and another dose was given with a similar result, but of shorter duration; the third dose was given and rejected within a few minutes. The dejections were now more copious and distinctly flocculent, and cramps of the legs commenced, adding greatly to the sufferings of the patient; the skin, however, was still above the normal temperature and dry; but the pulse was less forcible, though not materially accelerated. At this point I determined that the case was one of true cholera, and prepared to administer the stimulating injection proposed by Dr. Smith, viz. two ounces each of brandy and a strong infusion of green tea; I also sent for Dr. Smith, that he might see the case and observe with me the effect of his plan. The doctor arrived just as I was in the act of administering the injection. During the last twenty minutes a marked change had taken place in the condition of the patient; the skin had become cool and moist, the voice husky, the cramps increased in severity, the muscular knots on the legs were large, hard, and prominent, and unrelieved by the brisk friction that had been bestowed upon them; the nausea was constant, and there had just been at least a pint of discharge from the bowels and half that amount from the stomach—whey-colored and flocculent. Dr. Smith remarked that it appeared to be as well defined a case of cholera as he had ever seen. At this stage of affairs I administered the injection, composed, as before stated, of a wine-glass of brandy and a like quantity of strong green tea. Before the operation was fairly completed, the patient indicated that he was unable to retain the injection. I therefore seized a napkin, and as I withdrew the pipe, made firm pressure against the sphincter and maintained it steadily for about fifteen minutes—until the patient said he felt able to control it himself. *There was no vomiting subsequent to the administration of the injection,* and the nausea rapidly subsided; bottles of hot water were placed about the legs and body of the patient. The cramps continued, but with decreasing severity, for about an hour, when they ceased entirely. The coolness and moisture of the skin gradually disappeared; the pulse became fuller, and fell to 96.

There was but little change from this during the night; patient quite restless, but expressing himself as very comfortable, except for the thirst. I administered no further medicine except a pill containing two grains each of calomel and camphor, with one of quinine, once in six hours.

Mr. W. had no operation of the bowels for thirty-six hours after the one immediately preceding the injection; then he had a copious fecal evacuation—the result of half an ounce of castor oil, combined with a tablespoonful of the chloroform, etc., mixture, given twelve hours previously for that purpose.

Mr. W. had a slight fever for two or three days, but on Monday, the 24th instant, he was entirely recovered and went to his business.

It was my intention, during the progress of the above case, to have made a microscopical examination of the discharges, that the diagnosis of the disease should, if possible, have been more positive; but they were disinfected and thrown out immediately after passage; and my direction (given before the administration of the injection) to reserve some of the fluids for that purpose, was misunderstood. Fortunately for my patient I was unable to procure a subsequent specimen.

Respectfully yours,

F. N. Otis, M.D.

No. 108 West 34th Street.

QUARANTINE.

To the Editor of the Medical Record.

Dear Sir—In the last number of the Medical Record I have noticed a letter from Professor Post on the subject of Quarantine, and your remarks on the action of the "American Medical Association" on this subject at its last meeting. *I* fully agree with the Professor that "it is not fair to set down all who voted against the reference of this subject to Congress as *absolute non-contagionists.*" So far from it, it is well known that a large majority of the members were contagionists; in other words, believed in the *portability and infectious character of cholera.* The final vote to lay the question on the table had no special bearing on this point.

But what I wish briefly to consider are, the reasons Professor Post offers why "personal quarantine" especially ought not to be enforced; and these may be summed up under the following heads, viz.:

1. "The impossibility of excluding the pestilence by any quarantine regulations."

2. "The evils necessarily attendant upon a rigid personal quarantine" to the persons quarantined.

3. The injury inflicted by such quarantine on commerce, and those engaged in commercial operations.

4. Its effects on the public health, and as regards the treatment of the sick, etc.

1. In reply to the first objection, it may be answered, that quarantine, imperfectly as it has been carried out, has protected New York city for more than six months against the introduction of cholera; and if six months, there is no good reason why it may not for six years, or sixty. Owing to the want of proper buildings and accommodations on land, it has been impossible, of late, as cholera vessels and cholera patients have multiplied, to maintain a sufficiently rigid quarantine; and there is grave reason to believe that, in a few instances, the poison has been introduced into the city and probably carried to other places. Under better regulations, however, this need not, and would not probably have happened. There are numerous instances now on record where a rigid quarantine has proved perfectly successful in guarding against the introduction of cholera into a place or country.

2. In regard to the evils "necessarily attendant upon a rigid personal quarantine," under proper regulations and with suitable accommodations, they are more apparent than real. Cabin passengers would rarely have to be detained at all, and only such emigrants as have been exposed to the emanations from the sick, or their dejections; none but the emigrants on board cholera ships would have to be detained a single hour, and few such vessels can be expected to arrive at any of our ports, certainly at not more than three or four, and then at the rare interval of months or years.

In such cases ten days would ordinarily suffice for the period of detention, and passengers might be made as comfortable, and even more so, at the quarantine station than at the ordinary cheap boarding-houses and hotels in the city. Under regulations such as described by Dr. Marsden, of Quebec, or as sketched by Dr. Lee in your number for July 2d, no such evils as are depicted could possibly exist. Whether it is a fair mode of reasoning to assume that what is called a "rigid quarantine" necessarily presupposes that the present miserable arrangement is to continue in the future, it is unnecessary to discuss. No one can condemn the present barbarous system of confinement on board the vessels more than the present writer.

Assuming, what we have a perfect right to assume in the present state of our knowledge on the mode of pro-

pagation of cholera—for example, that it is not only possible, but very probable, that a rigid quarantine will exclude the disease—where is the inhumanity in endangering or sacrificing the lives and health of a whole community to prevent the possible inconvenience and hardships of a few emigrants? Which shows the greatest "narrow-mindedness" in opening wide the floodgates of foreign pestilence, or keeping them closed? If it is proper to feel "indignant" at the sacrifice of a few lives of "Scandinavians and Germans," what shall we say to sacrificing hecatombs of our American people to a theory which facts have abundantly demonstrated to be no longer tenable!

In respect to the argument, that "*personal* quarantine inflicts injury on commercial cities, by deranging the operations of commerce," it may be said to be more imaginary than real; a quarantine, like that proposed in the present instance, which admits, repels, and guards, after a day or two's detention and purification, can hardly be said to embarrass commerce to any degree worth naming; nor is it easy to see how the detention of emigrants or others for a few days is likely to exert any serious effect in this respect. The real question is—Which will have the most serious effect in deranging the trade and commerce of a city, the absence or presence of an epidemic disease? Compare the commerce of New York in 1832 with that of the present year, and we have a ready answer. And had our quarantine for the last six months been no more rigid than in 1832, in all probability our city would have suffered as much in this respect as during that year. Talk of persons "being thrown out of employment," and their friends being subjected to severe privations in consequence of a rigid quarantine in the lower bay! Why the absurdity of the proposition precludes any serious reply. But what would necessarily happen in case a cholera epidemic like that of 1832 should prevail in the city? Let the experience of that fatal year answer.

The other arguments advanced by Prof. Post are really unworthy of notice. What we have, as physicians, to deal with, are *facts*, not their consequences; we are not to be held responsible for these. If the poison of cholera is contained, for example, in the dejections of cholera patients, as is now generally believed, we are bound to act on that belief. If the cholera poison be an exotic, then we are obliged to treat it as such and keep it out of the country; and whatever measures are necessary to effect this, are perfectly proper and justifiable; commerce or no commerce, nothing can be placed in the scale against human life and health. It is unnecessary, in this enlightened and Christian age, to apprehend any abandonment or neglect of the sick, no matter what theories of disease may be adopted; and if any are to be found so ignorant as not to know the value of personal and domestic cleanliness, as preventives of disease, they are not likely to know very much about quarantine regulations, or even whether there are any or not.

On this subject of quarantine, the highest commercial authority, Mr. McCulloch, has laid down the true rule of action: "Whenever there is any doubt, *it is proper to incline to the side of security.*" Of course where there is no doubt, as in the present instance, there can be no hesitation whatever in regard to the proper course.

I am, sir, truly yours,

RECTUS.

QUARANTINE AT SAVANNAH, BRUNSWICK, AND DARIEN, GA.—The ports of the above-named localities have been subjected to stringent quarantine regulations, in accordance with recent instructions from the War Department.

QUARANTINE IN EUROPE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR—One of the principal reasons assigned for a belief in the theory of cholera originating in some peculiar epidemic constitution of the atmosphere, is the general failure of quarantine, as maintained in foreign countries. The "Epidemiological Society of London," for example, has expressed the opinion recently, that quarantine, ever so strict, will not keep cholera out of England. Such is the opinion of the ablest medical men in Great Britain. But does it thence follow, that quarantine against this disease is therefore useless for the United States? By no means. The two countries are situated very differently as bearing on this question. It is now well ascertained that the usual incubative period of the disease is within seven days, but may extend to fifteen, possibly twenty. Should cholera prevail in any part of the continent of Europe, persons who have been exposed to the infection, and have the germs of the disease in their systems, *may travel to the remotest parts of that continent during the incubative period and be then attacked, and thus create so many distinct foci* from which the infection may spread in every direction; and during this period no diagnostic signs of the disease can possibly be detected, for none exist. The "*London Lancet*," of May 12, 1866, admits this, and truly says that "the difficulties in the way of excluding the disease from England are insuperable." *Cholera-carries*, in the shape of German emigrants from Holland laden with infection, were landed in apparent health in English ports, before the cholera was even known to exist in Rotterdam, whence the vessels sailed, or even in Holland. Those were the emigrants who embarked on board the ships *England* and *Virginia*, and sickened with cholera during subsequent passages. So, last year, the cholera was introduced into Marseilles and other places on the Mediterranean coast from Alexandria, before the disease was known to exist in Egypt.

We are differently situated; the period of passage of ships between the United States and Europe is longer than the ordinary incubative stage of the disease: and in all probability persons embarking who have been exposed to the infection, have already had the germs of the disease in their system several days. Cholera ships can, therefore, with great certainty, be distinguished from all thers—and none others need to be quarantined. This is a safe and practical test, and simplifies the whole question greatly. I believe facts show very conclusively that if a person continues well ten days from the time of exposure, there is but little risk that he will afterwards have the disease unless he derives it from a new source. Hence the risk of a communication of the disease across the Atlantic is very small, and it will be our own fault if we have it introduced into this country at all.

Let us therefore hear no more of the argument (?) that because quarantines have failed in Europe, they must necessarily fail here. There is no analogy in the two cases. I do not say that Providence has placed us so far from the Old World, that we may be able to shut out from us all its infectious diseases; but I do say, if we do not use the means which have been kindly placed in our hands for this purpose, we shall be guilty of the most reckless neglect and indifference to the health and welfare of our citizens. Truly yours,

CHAS. A. LEE, M.D.

Peekskill, July 4, 1866.

PROF. FARADAY has received the Albert Gold Medal of the Society of Arts for his discoveries in electricity, magnetism, and chemistry.

Obituary.

PROF. R. D. MUSSEY, M.D., LL.D.

Reuben Diamond Mussey, son of Dr. John Mussey, was born June 23, 1780, in Pelham Township, Rockingham county, New Hampshire.

In his fifteenth year, after some preliminary training, partly of a home character, he became a pupil at the Aurean Academy, Amherst, N. H., and was there prepared to enter the freshman class in one of the New England colleges: but owing to limited pecuniary resources, which necessitated farming in summer and teaching in winter, he was compelled to submit to a temporary interruption of his plans for the future. Thus it was not until 1801, that, with the promised aid of a not over-wealthy father and with moderately recruited finances, he enrolled himself a junior in Dartmouth College. Immediately after gaining his Baccalaureate degree from that institution, in 1803, he entered the office of the late distinguished Nathan Smith.

But, in this instance also, in consequence of a compulsory acceptance of an academic appointment at Peterborough, N. H., his medical studies during the ensuing summer were mainly directed by Dr. Howe, of Jaffray, N. H. Still, this arrangement appears to have been merely temporary, and did not sever the relations between his original preceptor and himself. He received his degree of Bachelor of Medicine in August, 1805, after a successful public examination and an unusually logical defence of a thesis on Dysentery. A three years' residence in the south parish of Ipswich, now Essex, Mass., and a journey to Philadelphia, accomplished by means of such fees as he could collect, constitute a part of his early professional history. He profited largely by the advantages accruing from the teachings of Rush, Wistar, Physic, with others scarcely less distinguished; and obtained in the spring of 1809, from the University of Pennsylvania, his full medical degree. It is proper to add in this connexion, that during Dr. Mussey's stay at Philadelphia he challenged the attention of the profession by instituting, in his own person, certain experiments with the view of settling a question then only mooted, regarding the introduction of liquids into the system by cutaneous absorption. It is related of him, that after a three hours' immersion in a strong infusion of nutgalls, followed by a like proceeding for the same length of time in a strong solution of copperas, he did not, until the lapse of a week or two, regain his usual health. This last experiment did not establish his position as satisfactorily as the series conducted with madder and rhubarb as agents, although as a whole they very materially modified the teachings of Dr. Benjamin Rush, whose opinions then held nearly undisputed sway in the American medical world.

Departing from Philadelphia with his coveted diploma, he next resumed practice at Salem, a town contiguous to Boston, where with his professional colleague, Dr. Daniel Oliver, he divided the honor of having initiated a course of popular lectures upon chemistry.

After a residence at Salem of nearly six years, he accepted, in the autumn of 1814, the chair of the "Theory and Practice of Physic" in the Medical Department of Dartmouth College, from which institution he had derived his degree of LL.D. two years before. In 1819 he was chosen Professor of Anatomy and Surgery in the same school, a position which he retained until the close of the session in 1838. He also lectured on chemistry at the Middlebury College in Vermont during the summer of 1817, besides fulfilling on emergent occasions the duties belonging to the chairs of Materia Medica and Obstetrics, in the institution having the first claims upon his attention.

An absence of ten months upon the continent, dating from December 1829, was the only interruption to labors assiduously pursued in public and private; but even for these, with a rare conscience, he rendered a full equivalent by extra exertion and self-imposed tasks.

It is incumbent upon us also to mention that he delivered surgical lectures in the Medical School of Maine during the winters of 1830 to 1833 inclusive, as well as in a now discontinued institution, situated in Fairfield, Herkimer county, New York, for the successive seasons of 1836 and 1837; but neither of these courses, owing to a division of time as allotted to each, interfered with his duties as a medical teacher in his native State.

An invitation in the fall of 1838 to a Professorship of Surgery in the Medical College of Ohio, at Cincinnati, brought about a change of residence to the West. In 1852, he transferred his allegiance to the Miami Medical College, in the same city, by the acceptance of a corresponding position.

Besides these relations, he rendered continuous and eminent service in the Commercial and St. John's Hospitals, Cincinnati, and was the fourth President of the American Medical Association, having occupied the chair at the Charleston meeting in May, 1851.

Dr. Mussey was likewise prominent in the controversy regarding the bony re-union of intra-capsular fractures of the femur, of which question he maintained the affirmative, and challenged Sir Astley Cooper himself by a vertically sawed specimen, carried across the Atlantic. He also measured the weapons of debate with formidable adversaries at home, but with the merits of the contest it is not within our present province to deal.

Of the exact time when Professor Mussey removed from Cincinnati, or of the subsequent events of his life, we know comparatively little. A secular exchange chronicles the fact of his death in Boston, June 21, at the residence of a son-in-law, and makes the additional statement that "during the past two years he was confined to his bed by a disease, certain symptoms of which puzzled the acutest physicians."

We are also informed through the same source that "Professor Mussey's devotion to science was such that he left directions for a post-mortem examination of his body for the benefit of his profession."

As a surgeon, Professor Mussey was somewhat tenacious of his opinions, which he defended with vigor; was bold, self-reliant, original, thoroughly versed in anatomy, usually rapid in his conclusions, attentive to the details of his operations, and particularly anxious regarding the care due to patients on the part of attendants. He also had acquired the habit of tracing the results of surgical interference in the persons of the subject, even through a series of years, and was therefore seldom at a loss for an accurate, although generally unexpressed, prognosis.

In 1830, just before his visit to Europe, he removed a large, ulcerated bleeding nævus upon the head, after resorting to a ligature of both carotid arteries, at an interval of twelve days apart. The published account of this case met him upon his arrival in England, and at once introduced him into the choicest circles of the profession.

The *American Journal of Medical Science* at Philadelphia, 1853, contains the account of yet another operation of this class, in which both carotids were successfully ligated, for the cure of aneurismal enlargement of the arteries about the ear.

He has operated, also, with marked success in many

cases of osteo-sarcoma, was a brilliant lithotomist, could point to numerous cures of varicocele by subcutaneous ligation of the spermatic vein, and was besides a judicious surgeon in that large class of diseases having for their seat the genito-urinary apparatus.

Decided at length, not so much by the mental strain resulting from long continued, unremitting labors, as by the desire to pursue at leisure the inviting paths opened by the critics and philosophers of his profession, he consented to relinquish a practice, lucrative to be sure, but grown large enough to be unwieldy. This step taken, though it was about the close of his seventieth year, in all likelihood deprived him of some additions to his surgical laurels; but there was no disturbance of his mental serenity, since with him the desire for mere popular fame occupied a position indeed subordinate.

Unless, however, Dr. Mussey's early habit of omitting to record his cases has been in a measure corrected during the wane of a long life, much that is valuable has been irrecoverably lost to the profession.

It is to be hoped that his literary remains, if any there be as yet unpublished, may receive proper consideration at the hands of executors.

One of Dr. Mussey's sons was Brigadier-General R. D. Mussey, who till recently was President Johnson's private secretary.

In private life he was an earnest, conscientious Christian, rigidly abstemious in his habits, and for many years reputed to be a practical vegetarian.

Medical News.

Personal.

As changes in the *U. S. Army Medical Department*, we notice that Brevet Lieut.-Col. C. C. Keeney, Surgeon U. S. Army, has been ordered to accompany Major-General Halleck, commanding Military Division of the Pacific, on a tour of inspection through Nevada, Idaho, Oregon, and Washington Territory.

During the temporary absence of Brevet Lieut.-Col. Keeney, Brevet Col. Murray, Surgeon U. S. Army, will, in addition to his other duties, attend army officers and their families in the City of San Francisco, Cal.

The resignations of Surgeons H. Lawrence Sheldon and David O. Farrand have been accepted, to take effect July 1, 1866.

Permission to delay reporting to the Commanding General and Medical Director to the Department of the Platte for twenty days has been granted to Brevet Major Philip C. Davis, Assistant Surgeon, United States Army.

Assistant Surgeon J. B. Petherbridge, United States Army, recently appointed, is ordered to report in person without delay to the Post Surgeon at Carlisle Barracks, Pa., for temporary duty.

Brevet Lieut.-Col. John J. Milhau, Surgeon U. S. A., has been ordered to Hart's Island, N. Y., to investigate and report upon the recent outbreak of cholera at that locality. A corps of civil physicians will coöperate with him in the adoption of such measures as the exigencies of the case may demand.

In the corresponding department in the *U. S. Navy*, the following orders have been recently promulgated: Wm. V. Marmion, George S. Culbeth, J. N. Kidder, Ernest D. Martin, Thos. K. Brown, Adam Trace, Robert A. Wheedon, Edward H. Ware, are to be Assistant Surgeons; commissions to date from June 25.

The resignations of Assistant Surgeons William C. Cook and John Philbrick, were accepted June 28.

The following officers have been ordered: Assistant Surgeon James M. Flint, from the receiving-ship at Baltimore, to the Naval Academy at Annapolis; Surgeon T. M. Potter, to the naval rendezvous at New York, to relieve Surgeon J. S. Kitchen, who is placed on waiting orders; Passed Assistant Surgeon H. L. DuBois, to duty in the North Pacific Squadron; Assistant Surgeon Robert A. Whedon, to the Naval Hospital at New York.

The following have been detached: Acting Assistant Surgeon E. A. Dulin, from the Pampero, and waiting orders; Assistant Surgeon William V. Marmion, from the Naval Hospital, New York, and ordered to the steamer Bienville.

Acting Assistant Surgeon Perley H. Johnson has been honorably discharged, to date from June 26.

Dr. Samuel R. Percy, Special Inspector of Milk by appointment of the Health Board, having completed his duties, has been accordingly relieved.

Dr. Paul Beck Goddard died at Philadelphia on the 5th ultimo, after a brief illness. His devotion to wounded soldiers, during the war, gained him great popularity among the people. For a man of so much ability, he had singularly little to do with the pen; but few physicians in the country have had so large a practice, and its demands were no doubt greatly varied and exacting. In cases testing the resources of the medical art and science, he was summoned frequently; and in a city somewhat distinguished for well educated physicians, his rank was deservedly high. Like many of the great lights of his profession, Dr. Goddard was, apart from medicine, a wit and scholar.

Dr. Wm. R. Donaghe, formerly a prominent medical teacher and an alumnus of the University Medical College, class of 1852, died July 18, in this city, aged 36 years.

PROGRESS OF THE CHOLERA.

In Syria and Egypt, the cholera has reappeared, but it is more of a sporadic than an epidemic character, and is steadily diminishing.

In Europe.—"Riveted by the war which has broken out on the Continent, public attention for the moment has been diverted from the cholera.

"The progress of the disease in Eastern as well as Western Europe has, however, during the past month been such as to require narrow attention.

"The epidemic has broken out in Jassi, Focktchani, and other towns of the Moldo-Wallachian territory. It is to be presumed also that the malady has resumed its activity in the south-western provinces of European Russia, as active measures against it have been already adopted in St. Petersburgh.

"In Holland the disease is widely prevalent. From its first appearance in May (?) to the 13th of June, 724 cases and 431 deaths have been reported in Leyden; 216 cases and 135 deaths in St. Gravenhage; 396 cases and 220 deaths in Delft; 708 cases and 433 deaths in Rotterdam; 100 cases and 50 deaths in Gouda; and 305 cases and 169 deaths in Utrecht. In Prussia cholera has declared itself in Stettin, Berlin, Sweinemünde, Frankfort-on-the-Oder, Naustadt, Eberwald, Cammin, Arnswalde, and several villages. From the 2d to the 9th of June there were 103 fatal cases in Stettin. Sixty-five cases occurred in two days at Arnswalde.

"The disease has not yet shown much activity in Berlin and the vicinity—the cases, indeed, would appear to have been scattered mainly in the suburbs.

"The epidemic still lingers in the neighborhood of Altenburg (Saxony), and it is reported to have shown itself at Chemnitz and near Echternach, on the Rhine.

"The need of watchfulness at Liverpool is taught by what has befallen Antwerp. A short time ago cholera broke out on board an emigrant ship, the Agnes, in Antwerp port. The disease has now appeared in the city, and to the 16th of June there had been eighty-four deaths and 180 cases, irrespective of those which had taken place among the emigrants on board the Agnes. In France the epidemic has broken out in several places, and it was recently prevailing wi h great intensity at Amiens. Cholera still shows itself from time to time among emigrant ships sailing from Liverpool to the United States.

"The latest news from the East, while confirming the information of cholera having appeared among the returning Mohammedan pilgrims at Jedda, leads to the conclusion that the previous reports of the number of cases there were exaggerated. One of the caravans on the route to Medina is, however, believed to have suffered severely. The pilgrims who had reached and traversed Lower Egypt were said to be entirely free from the disease."—*London Lancet*, June 27.

We may add to the above the following:

Total of cholera cases at Stettin from June 2 to the 25th, eight hundred and ninety-four; total of deaths, five hundred and one. Two men in a regiment lately sent from Stettin to Leipsic, were attacked at the latter place.

The Paris correspondent of the London *Daily News* writes:

"We happily hear of no cholera occurring in Paris, but it has not yet disappeared from Nantes, and to-day some cases are reported from the barracks at Aire in the Landes, where three soldiers are stated to have died of it, but no civilian had been attacked. At Amiens, where there has been cholera for some time, the deaths are reported as twelve on June 23d, and nineteen on June 24th."

Dr. Harris, in an official letter of the 20th ult., in regard to the prevalence of the epidemic in Europe, uses the following language: "In Europe, as we were informed by the correspondence of the chief sanitary authorities, cholera has been gradually progressing northward and eastward. It has now reached St. Petersburgh, after spreading very slowly through the southern provinces of Russia, and in the northern German States during the winter and spring. In Prussia also, and in Saxony, the epidemic has lingered with great tenacity, and not the less on account of the massing of military forces. In the city and vicinity of Altenburg, where one wing of the Prussian army rested previous to the movement into Bohemia, the epidemic has reappeared with the same violence it exhibited on the same ground last autumn and winter."

In the United States, the pestilence, according to various authorities, has declared itself sporadically in Norwalk and New Haven, Conn., in Jersey City, N. J., and somewhat alarmingly in Brooklyn, N. Y., particularly in a certain quarter notorious for its contempt of sanitary laws. In New York City itself the daily average of cases is still not large; but owing to the early date of going to press, we refrain from giving statistics which may prove neither accurate nor valuable upon the appearance of the Record. A recent inspection of some thirty vessels declared an entire abatement of the scourge at the Quarantine station in the Lower Bay.

The disease has also appeared on Governor's Island, but as yet only one case has been reported, and that is under control. The same may be said of the disease on board the *San Salvador*, which sailed some days ago with sixty cabin passengers and four hundred and seventy-three recruits for the regulars now in Florida, and four officers. Thirteen cases occurred just previous to their landing on Tybee Island. There were but three deaths. Many of the recruits were said to be recent emigrants. No cases occurred among the cabin passengers; the troops are all comfortable on shore, and the sickness is subsiding.

Hart's Island, a Government Depôt, has also been visited, and we regret to announce among the victims James Theodore Calhoun, Assistant Surgeon U.S.A., and Medical Director of the Post—a noble, self-sacrificing, and devoted officer.

A fatal case also occurred in Cincinnati, Ohio, on the 17th ult., in the person of a German woman, an inmate of a crowded tenement-house in a filthy quarter. The locality is the same where the epidemic first appeared in 1849.

University Medical College, New York.—The University Medical College have effected a lease of the North House, on the New York Hospital grounds. The college will, for the present, be carried on in that building, by virtue of an arrangement made with the Governors of the Hospital.

Dr. J. W. S. Gouley has been appointed Professor of Clinical Surgery, and Dr. D. B. St. John Roosa, clinical professor of diseases of the eye and ear.

Vermont State Medical Society.—The semi-annual session of this society was held June 14, at Brattleboro, Vermont. Dr. Rockwell, of the Vermont Lunatic Asylum, read a paper on the Treatment of Insanity. The following papers were also read: On Dysentery, by Dr. Bullard; On Scarlatina, by Dr. Sperry; On Diphtheria by Dr. Holton; and on the Treatment of Cholera, by Dr. Butler. The meeting was well attended.

Abandonment of Seguine's Point as a Sanitary Emigrant Station.—In compliance with the petition of Mr. Seguine and other inhabitants of Richmond county, Judge Barnard, of Kings county, has granted an injunction restraining the Health Commissioners, the Commissioners of Quarantine, and the Commissioners of Emigration, from using Seguine's Point or any other part of Richmond county for quarantine purposes. The Richmond County people allege that the seizure of Seguine's Point was in violation of a State law forbidding the erection of quarantine buildings within a mile and a half of Staten Island shores. All the expenditures for improvements, etc., are of course lost. As a last resort, if the Board are compelled thereto, they will land passengers and care for them at the Battery Barracks.

The Malta Board of Health has established a quarantine of seven full days for all arrivals from Liverpool.

Connecticut State Lunatic Asylum.—Thirty-five thousand dollars have been appropriated by the late Legislature of Connecticut towards the erection of a State Lunatic Asylum.

The Verplanck State Hospital.—The New State Emigrant Hospital on Ward's Island, the corner-stone of which was laid August 10, 1864, was formally named on the 13th ultimo, the Verplanck State Hospital, in honor of the President of the Commissioners of Emigration; and has since been opened for the reception of patients. The event was celebrated by the Emigration Commissioners and the Board of Trustees of the Irish

Emigration Society, by an excursion to the island, and a dinner, followed by speeches, at the house of the Superintendent. The cost of erection will reach in the aggregate about three hundred thousand dollars. The buildings, five in number, are arranged upon the pavilion plan, the central structure being three stories high, the remaining four two stories high, separated by a wide court-yard, completely isolating them from each other. The wards are situated upon the southern portion of each pavilion, being sheltered on the north by the dining-room, nurses' apartments, closets, hall, etc., by which an equalized temperature and additional facilities for ventilation are secured. Large corridors also connect the pavilions, and serve the purposes of a sanatorium for convalescent patients. Steam from boilers in a disconnected building, located near the centre of the hospital, at once supplies the kitchen, laundry, and bakery, as well as warms the structure as a whole.

The wards, ten in number, will accommodate 300 beds; and when necessary their capacity may be increased to 200 more, with the only disadvantage of reducing the allotment of air from over 1200 cubic feet for each bed to 700 cubic feet.

With these conveniences for comfort, cleanliness, and perfect ventilation, it is claimed that this hospital will rank among the finest and best arranged in the world.

The Rinderpest.—The cattle plague still exists in Great Britain, although it is authentically stated to be on the decline. 987 occurred during the week ending June 9th.

Physician to the King of the Belgians.—Dr. Eustace Smith, of London, has been appointed physician to His Majesty the King of the Belgians.

Prof. Flint's recent work on Practical Medicine has met with a very favorable reception in Great Britain. The *London Lancet* thus speaks of it:—"The old routine of description and prescription is not observed, and in the plan of the work, and the treatment of individual subjects, there is a freshness and an originality which make it worthy of the study of practitioners, as well as students. It is indeed an admirable work, and highly creditable to American Medicine. For clearness and conciseness of style, for careful reasoning upon what is known, for lucid distinction between what we know and do not know, between what nature does in disease and what the physician can do and should; for richness in good clinical observation; for independence of statement and opinion in great points of practice, and for general sagacity and good judgment, the work is most meritorious. It is singularly rich in good qualities, and free from faults. Dr. Flint does not care from what source he derives material for the formation of opinion, and he is always explicit in his statement of the source. He defers greatly to physiologists and chemists, but has a keen perception of the point at which they cease to help the physician; and beyond this point, and in the absence of these guides, he comes to the best opinion to which his long and close clinical observation enables him to come."

It is certainly very pleasing to be able to record from such a source such a high opinion of an American work. It is not only a gratifying recognition of the services of the author, but it is a compliment to the medical literature of our country.

Quacks in Chicago.—The Chicago *Post* gives an account of a quack doctor who was brought to the witness-stand in one of the Courts in this city, and appeared so profoundly ignorant of the science of medicine that some inquiries were made of his career and method of practice, which caused some curious revelations. He had practised as a physician in Chicago for twenty years. He had never been at any university. He had never obtained a medical diploma. He knew nothing whatever of medicine or surgery. He could speak German and a few words of English, but knew nothing of any other language; and was in fact, upon all general subjects, deplorably ignorant. Yet this man had actually practised as a physician in this city for twenty years, and had accumulated a handsome fortune. For a young girl who was dying with consumption, he ordered that a compound of coal-tar, vinegar, and assafœtida should be put in a large jar and kept constantly stirred by her side; and although the stench was horrible, the sufferer had to breathe it till she died.

A patient was suffering from sore eyes. The learned physician told her, with great solemnity, that the fat which was to work the cure must be the fat of a cat. Furthermore, that the cat which gave the fat must be black. A single streak of white would spoil the charm, and the fat of a grey or brindled cat would strike the patient stone blind.

A New Hospital at Washington, D. C.—The ceremonies of laying the corner-stone of the building for the Providence Hospital on Capitol Hill, took place during the past month. Archbishop Spalding, of Baltimore, officiated. Father Maguire, President of Georgetown College, the Rev. Dr. Samson, President of Columbia College, and a number of members of Congress and other officials were present. The Providence Hospital was founded by the Sisters of Charity of the District of Columbia. During the war it was used by the Government as a hospital for our sick and wounded soldiers, and was under the management of Sister of Charity Mary Carroll.

Yellow Fever at Vera Cruz.—Recent advices inform us that "in consequence of the accumulation of dirt in this city the yellow fever is raging badly, and the place is almost deserted. During one week of the past month the average number of deaths per day was about fifty. On one day in particular fifty-three men died in one hospital alone. At this time the fever still rages fiercely, and the hospitals are all filled."

Lunacy in France.—A recent report shows that in France, in 1865, there were no less than eighty-four thousand lunatics, being about 1-429 of the whole population. To persons subjected to hard mental labor it will be a consolation to find that out of that large number only three hundred and fifty-eight cases are attributed to intense mental application, so that it may be inferred that the brain will sustain more wear and tear than any other part of the human frame. Religious feeling carried to excess produced one thousand and ninety-five cases of lunacy.

The United States Marine Hospital at Cincinnati was sold at auction, on Thursday, for $75,000. It cost the Government $250,000 ten years ago.

Clitoridectomy.—The new operation of amputation of the elitoris, proposed by Baker Brown of London for the cure of epilepsy, is being rather severely criticised by some of the British surgeons. They contend that the procedure is unwarrantable, and that it is unattended with any good result. This is only another of the many proofs of the tricky character of "hobbies" when an attempt is made to ride them by parties not specially interested.

Original Communications.

HOMŒOPATHY AND CHOLERA.

By A. P. MERRILL, M.D.,
OF NEW YORK.

In regard to an epidemic disease which has everywhere and under every plan of treatment proved so intractable as cholera, and which is scarcely less fatal now wherever it prevails than when it first appeared, it is proper to notice the amount of success which has attended upon every form and variety of management; and especially is it desirable to inquire into all comparative results, as set forth in the reports of different systems of practice. And without reference to details which are familiar to those acquainted with the literature of the subject, it can scarcely be doubted that the claims of homœopathy, now once more so persistently urged, are not to be wholly disregarded. But it must be considered that the proofs adduced in favor of any plan of treatment, however abundant and well authenticated, are in general by no means conclusive; because it is true of cholera, as of most other epidemic diseases, that in ascertaining the average rate of mortality, much depends upon the number of cases of a mild grade of the disease which are embraced in the account. In the published reports this subject is not often referred to.

I have known a physician of celebrity in the South to rate his loss of patients in the whole course of an epidemic of yellow fever at five per cent.; but when requested to confine his estimate to such of his patients only as were confined by the disease to their beds for one or more days, his rate of mortality was increased to eighty per cent. The proportion of cases of a mild grade was of course large, and many of them were doubtless within the control of the remedial powers of nature; but in so fatal a disease it would have been imprudent to have entrusted any one case to those powers alone. As in cholera, the insidious character of yellow fever, in its early stage, renders it quite impossible to determine what will be its grade of severity at a later period, in any case that occurs.

Now, there are good reasons for believing that the proportion of mild cases in most cholera epidemics is even larger than in epidemics of yellow fever; and certainly there are better chances of recovery from an advanced stage of cholera without medical treatment. In the latter disease spontaneous reaction sometimes takes place in the stage of alarming depression of the vital powers, unexpectedly inaugurating a stage of convalescence; but in the latter and corresponding stage of yellow fever there is little hope of relief, except from the appliances of art. More dependence may be placed upon the curative powers of nature in cholera, therefore, than in yellow fever, and most other epidemic diseases of a fatal character; and in making up the percentage of mortality there is a greater necessity for information in regard to the proportion of mild and tractable cases. Without this the question of successful treatment is involved in great uncertainty. Indeed, there is little reliance to be placed upon statements which are not confined to such subjects only as have suffered from the graver grades of the disease, as evidenced by cramps, thirst, cold sweating, husky voice, and sinking pulse. I do not include vomiting and rice-water dejections from the bowels, because these are sometimes wanting in dangerous attacks of the disease.

But after making due allowance for advantages that may be taken of mild grades of cholera in making up death-rates, it is not to be presumed that many persons are admitted into cholera hospitals without really having the disease at all; and it seems undeniable that a degree of success has attended upon homœopathic treatment in certain hospitals, which is deserving of serious attention. Admitting any considerable success from this plan of treatment, the question to be determined is—What explanation can properly be given of it? Is it due to the alterative power of infinitesimal medication—to remedial agents in doses of a decillionth of a grain? This is, of course, impossible; for the causes of disease and the remedies alike must necessarily act upon the system to produce changes in functional movements, without which healthy function is not impaired, or disordered function remedied; and it is not to be believed that in either case these changes are produced by agencies less active than the common aliment required to support life and health, or less active than those excitants and sedatives which in their operation come short of producing either disordering or restorative effects. Disease, therefore, cannot be cured by infinitesimalism as interpreted by Hahnemann, and we must seek some other explanation of the boasted success of homœopathy in cholera.

After due investigation, my own conviction is, that this explanation is to be found in the fact that besides the adoption of a rigid and useful regimen, certain injurious medication is withheld by the homœopathic practice; thus realizing the hope of the expectant system in securing to patients the benefits of the remedial powers of nature. Cholera patients sometimes recover, but are not cured under such treatment; just as some persons recover from pneumonia, scarlatina, and infantile convulsions, without medicine of any kind, affording a delusive hope of a successful treatment of these diseases by means of regimen alone. And the homœopath has the additional advantage in the case under consideration, before referred to, that the reactionary tendency which often leads to recovery is stronger in cholera than in either of the diseases above named, affording in some cases reason to believe that the patient has been rescued from impending death, even in spite of unskilful treatment, by the remedial powers of nature alone.

It is notoriously true that, in both professional and non-professional treatment of cholera, opium in some form is almost always relied on as a prominent remedy. Whatever may be the character of other appliances for relief, whether they be external or internal, whether purgative or astringent, stimulating or contra-stimulating, opium appears as a concomitant prescription; and the fact that its use has been condemned by certain prominent physicians, imposes little restraint upon this common and favorite practice. The painful cramps, the prostrating influence of congestion, and the exhaustive discharges, appear to demand the application of a popular remedy which is nearly always at hand, and the comforting effects of which are familiar to the agonized patient and his anxious friends. Even although there were no encouragements to the use of opium derived from the opinions and practice of physicians, the temptations to employ it in a disease so formidable and distressing would be almost irresistible. But when its use is sanctioned by prominent medical man, by boards of health, and by sanitary and benevolent associations, not to mention the thousand secret nostrums which depend upon the soothing influences of this deceptive drug for their favor with the people, we cannot wonder that the use of opium in the treatment of cholera is almost universal. The homœopaths are an exception. They either do not use opium at all, or, if true to the principles of Hahnemann, they give it in doses so inconceivably small as to preclude all possibility of influencing bodily function, whether to produce like or unlike effects. Of

course this and all other remedies thus used are quite harmless of evil effects upon the system. This can scarcely be doubted when it is known—such is the smallness of the dose—that if all who have ever had cholera had been treated with opium homœopathically, the quantity that would have been given up to the present time would not amount to a single grain.

Experience in the treatment of epidemic diseases somewhat extended, has convinced me of the truth of the opinion sometimes proclaimed by others, that opium is injurious in those diseases which in their progress involve the pathological condition of congestion or inflammation of the mucous tissues, especially those of the digestive organs, excepting only in their inceptive and irritative stage. Gastritis from any cause, and particularly when it appears as a local lesion of yellow fever, is a remarkable illustration of this; and it is true also of diarrhœa, dysentery, cholera-morbus, and Asiatic cholera. Yet in all these diseases the initiatory stage is always characterized by more or less of nervous irritation, for which opium is a useful remedy. The dangerous use of opium in these several diseases results from a want of discrimination between this irritative and the congestive stage following it, a discrimination which the non-professional cannot be expected to make; and therefore it is unsafe to entrust them with the use of opium in cholera at all. The common addition of camphor affords no security against the mischievous effects of opium in this and other diseases to which the remedy is unsuited.

Nearly all the secret nostrums sold as remedies for cholera, as well as the prescriptions made by physicians for popular use, contain opium in some form, and it is the influence of this ingredient over the forming stage of the disease that gains for them some degree of public confidence. For every slight derangement of the stomach and the bowels, whether it be of the choleraic character or not, people resort to the use of these remedies, and in many cases they afford relief. This is sufficient encouragement for perseverance in their use in other cases not relieved, until that stage of the disease supervenes when the dose that was useful in the beginning becomes about the most injurious of any that can be taken; and thus is a most insidious disease rendered unmanageable by the persistent use of an insidious and deceptive remedy.

From an early period in the history of medicine, opium and other neurotic remedies have been successfully employed in the treatment of febrile diseases in their inceptive stage; and this practice appears to have been about equally in vogue among the advocates of two opposite and rival systems of pathology, the humoral and the nervous. And it is true of this treatment of fever, as of the treatment of cholera, that the success of opiates in the early stage has led to the continuance of these remedies at a more advanced period, when vascular engorgements and impairment of secretion render them inappropriate. There may be some exceptions in typhous, as I am sure there are in pneumonic fever; but in yellow fever, which is complicated with gastric lesions, and other forms of periodic fever complicated with other lesions of the abdominal and digestive organs, congestions and inflammations, generally most formidable in the mucous tissues, with consequent derangement of secretion, absorption, and nutrition, follow closely upon the disordered innervation with which the disease begins, constituting an alarming pathological condition strongly contra-indicating the use of opium. The uniform effect of this remedy in such cases is, to increase and intensify the alarming symptoms; and in the graver forms of fever in hot climates, its exhibition often proves fatal.

And these remarks are, I believe, equally applicable to cholera, which disease, both in its inception and progress, closely resembles in many respects the febrile affections above referred to. Although benefit may be derived from the use of opium in the primary stage, when nervous irritation constitutes the whole pathology, and neurotic remedies are specially indicated, the period of vascular congestion soon succeeds, as an invariable effect or sequence of such irritation unrelieved by treatment, when opium becomes injurious because of its tendency, as in febrile affections, to increase and intensify these congestions. Bloodletting is the more rational and effective remedy, as it is in the corresponding condition in fever, and it is in this stage that it has been successfully applied, even by the ignorant natives of India.

But under any system of treatment which has yet been devised for the relief of congestion, excepting only by the use of chloroform internally, which means I have so often urged upon the notice of the medical profession, morbid or febrile reaction is the only favorable result to be expected. In cases of severe and long continued congestion, especially when relieved without bloodletting to reduce vital power, this febrile reaction is sometimes too violent to be controlled by any known plan of treatment, and the patient is doomed to succumb to a fatal form of fever, after all the symptoms which may have characterized cholera in the previous stage of the disease have entirely disappeared. In this case it is as if he had suffered from a severe and long continued chill, followed by a violent febrile exacerbation, with every normal function impaired, and every healthy secretion either vitiated or suspended. The congestion under which the patient labored being of a sthenic character, there is a corresponding exaltation of vital energy in the resultant reaction; and if the unfavorable influences of opiate remedies be superadded we can have little hope for final relief. The mercurial treatment is the most efficient countervailing measure, and this sometimes succeeds by incurring the penalty of a distressing ptyalism.

It is the proper business of physicians to cure these and other destructive forms of diseases by treatment, without which the profession sinks into comparative discredit; but hitherto the experiments made with cholera can scarcely be considered less than lamentable failures. The rate of mortality is the same now as when the disease first appeared. The rule of one death out of every two severe cases, or cases which have passed from the irritative to the congestive stage, holds as generally good now as in 1832; and the same rule is observed in the booths and arbors of India as well as in the tenement-houses and hospitals of Europe and America. Greater success, with rare exceptions, has only been made out anywhere, by including a large proportion of mild cases, or cases which have been successfully treated in the inceptive stage of the disease—in which stage, all the world over, cholera is among the most tractable of all epidemic diseases. In this stage it is cured by a great variety and a small amount of medication. While we have other and more successful methods of treating the disease in its more advanced stages, and especially while we can resort to such effective remedies for congestion as chloroform internally and strychnia, it can scarcely be justifiable to persevere in the opium treatment; nor can it be considered expedient or proper to recommend to the non-professional and uninstructed such a remedy as opium, which in a large majority of cases must, in their hands, prove injurious and destructive to life.

Homœopathy may boast of success under the disguise of a placebo, and expectancy may claim the advantages of abstinence from heroic remedies, and both find con-

solation in the benignant powers of nature; but a noble profession, whose aims and purposes are the preservation of human life, should not be content with anything short of the adoption of remedial measures for so fatal a disease, which promise positive and beneficent results in every individual case.

141 McDougall street, New York.

LARYNGOSCOPY.

By J. SOLIS COHEN, M.D.,

OF PHILADELPHIA.

No. II.

It has been considered by a good many observers a highly desirable object to secure some method of *magnifying the image formed on the laryngeal mirror.* This was first attempted (Wertheim) by the employment of a concave laryngeal mirror; but this is objectionable on account of the varying focal distance from the reflected surface of the parts thus reflected; for it exaggerates the image in the centre of the mirror, while it so distorts the image of parts mirrored near its margins as to render useless any deduction drawn from such reflection. Turck endeavored to magnify the image by attaching a magnifying lens behind the central perforation of the reflector; he also used strong convex spectacle glasses; and subsequently arranged a small Galilean telescope on a separate arm attached to the stand of his reflector, so that the objective could be used behind the perforation, or brought to the edge, a small notch being cut from the margin to allow the glass to be kept within its circumference. By means of the arm carrying the magnifier, the instrument could be readily placed in the proper axis. Voltolini made similar experiments, using an opera-glass from which he had removed the ocular; and he also adapted a small telescope, but reports that he could obtain satisfactory results only by sunlight; and that even then it was necessary to have the head of the patient firmly held in a stationary position. Semeleder, in commenting upon these magnifiers, very justly remarks, that he cannot admit of the necessity for such an apparatus, or even its usefulness; for alterations so slight as not to be detected with the unaided eye, or with the employment of ordinary spectacles, can hardly cause sufficient discomfort to give occasion to an examination.

To increase the extent of image reflected, double mirrors (Czermak) are sometimes employed; in which a smaller mirror is attached by a short shank to the ordinary laryngeal mirror, at such an angle in front of it that the image of parts reflected on its surface, when in position, shall be again mirrored in the larger one. For viewing special individual parts, particularly of the posterior wall, which cannot be well seen by the simpler method, these mirrors are applicable; but considerable practical experience becomes necessary to render them useful; for the image of the second mirror, with its contents, appears on the first mirror, these contents being doubly reflected; while at the same time, in the same mirror, receiving this second doubly-inverted image, is also depicted the singly-inverted image of the parts reflected upon it. It requires some facility of abstraction to fully comprehend this arrangement, and compare the two images, reducing them in the mind so as to secure a clear conception of the natural relations of the structures in their entirety.

Another form of double mirror consists of an ordinary rectangular mirror, with a narrow strip of mirror adjusted at its side at an obtuse angle (Wertheim), and secured in the same setting, which is then broader than it is long, thus securing an increase of reflecting surface. Voltolini speaks of angular mirrors, two laryngeal mirrors close together at an angle, which he employs when the epiglottis cannot be well raised from the laryngeal aperture; in which case, one mirror is intended to be placed under the epiglottis; but his efforts in this direction, however, have not been very successful.

It was at one time thought desirable (Mandl) to scratch a graduated scale across the surface of the laryngeal mirror, sometimes in one direction and sometimes in others, with a view of measuring accurately the size of the various structures reflected. This diminishes the reflecting power of the mirror, scattering the rays along the line of the scale, rendering the image indistinct at these points; and it may sometimes happen that the scale may render the image imperfect at the very point desirable to be discerned clearly. For practical purposes, the eye should be trained to judge unaided of the relative size of portions of the image. For detailed and minute investigations into the physiology of the mechanism of vocalization and kindred subjects, such a scale may be desirable; but even then, in accordance with the suggestion of Semeleder, the scale might just as well be scratched upon the margin.

There is a second method of examining the interior of the larynx, exceedingly artistic in conception and beautiful in execution, but unsatisfactory for practical surgical purposes. This is called *translumination*, or *illumination by transparency.* It was first practised by Czermak, and takes advantage of the interspace existing between the delicate sterno-hyoid muscles covering the anterior portion of the larynx. A laryngeal mirror is introduced into the pharynx, and the light is concentrated exteriorly upon the skin covering the larynx, instead of being directed into the mouth. The result is satisfactory only where the neck is long and the tissues thin; and then, only such parts of the larynx can be illumined in this manner as consist of membranous structure; as the thyro-hyoid membrane, and the middle cricoid ligament.

The interior is thus brightened by a translucent ruby glimmer, shading off as do the margins of the fingers when we look at sunlight through them; and the vocal cords and other transparent tissues can be faintly discerned. As a refinement of the art, a demonstration of this kind produces a charming optical effect; but there is no practical advantage to laryngoscopy to be derived from this method of translumination.

In the Examination of the Patient, the operator must occupy a position directly in front of the person to be examined.

Where the sun is shining brightly; it is sufficient to place the individual with his face towards the light, so that the back of the pharynx is brought distinctly into view; and then to introduce the mirror while the patient is making an inspiration. It is in these cases, where direct sunlight can be employed, that *the simple laryngeal mirror is the only instrument absolutely necessary* for the successful performance of laryngoscopy. If from any cause such a position is inconvenient or unattainable, the patient may be placed with his back or the side of his body towards the sun, and the light be reflected into the pharynx from the observer's forehead, or from a mirror held in the hand, or attached to a stand. When the direct rays of the sun are thus employed, the reflector need not be concave; but when the diffused daylight of a room is used, a concave reflector becomes necessary. In using a concave reflector, care must be taken that the rays be not concentrated in a focus in the throat of the patient; and this remark is also applicable to the use of the reflector by artificial

light. The best mode of examining the larynx by sunlight has been found (G. Johnson), "to place a looking-glass in such a position that it shall deflect the sun's rays on the frontal reflector, but leave the eyes of the operator in the shade. In this way we avoid the serious inconvenience which results from exposing the eyes to the direct rays of the sun. Both the patient and the operator are in the shade, a column of light being turned upon the frontal reflector by the looking-glass." The frontal reflector is of advantage in these examinations, on account of the facility with which the direction of the light can be altered as the time of day advances, when a heliostat is not employed.

For the consulting-room it is well for the patient's seat, as well as the seat of the operator, to be provided with a screw, so that it can be arranged to any desired height. The piano-stool, where they have it, furnishes such a seat at the patient's residence. It is sometimes an object to support the head in a desired position, especially in the performance of operations within the larynx; and a head-rest similar to that usually employed by the dentist or the photographer, may be attached to the seat, and made capable of being raised or lowered at pleasure; or what appears to be still better, a circular padded ring sloped so as to fit the back part of the head, and secured to a sliding-rod by a ball and socket-joint furnished with a set screw working through the socket, so that the head-rest can be placed in the desired position and retained there (Tobold). Von Bruns employs two rectangular boards joined at a right angle, and so placed that one of them shall receive transversely the back part of the head, and the other support the right cheek of the patient. The apparatus bears a striking resemblance to the hod of the laborer. A dentist's spittoon, or some similar contrivance, should be at hand, and may be conveniently attached to the examination-chair of the patient (Elsberg).

Examined by Artificial Light, *the patient should sit erect, with the head inclined but slightly backwards.* The observer should face him at a proper distance for distinct vision of the pharynx, at the spot where the laryngeal mirror is to be applied.

If the examination is made during the daytime, the room should be darkened, but it is unnecessary to carefully exclude every particle of light. A lamp or gas-light, capable of being elevated or lowered at pleasure, should be placed at the side of the patient on a table of convenient height, so that the flame should be on a level with the ear, and a little behind. The reflector being arranged in front of the lamp at its proper focal distance, the observer should so regulate his own position that his eyes will be on the same plane as the mouth of the patient. When the light annoys the patient, or heats his face too much, it may be protected by a hand-screen, a fan, a few sheets of paper, or the fingers of the hand nearest the light. Turning the patient's head slightly inwards, and towards the lamp, a disc of light should be thrown from the reflector over his lips, so that when the mouth is opened, the posterior wall of the pharynx just below the base of the uvula will be at the near point of vision. The most favorable position for the head of the patient will be, in the majority of cases, when the lower border of the upper incisor teeth is on a horizontal plane with the line of union of hard and soft palate. The mouth should be widely opened, and the tongue thrust forward with some muscular force; its body lying on the floor of the mouth, and its posterior portion and base as much hollowed as possible. It may be extended in a straight line, or slightly inclined to the side furthest from the light. The patient should breathe rather deeply, but quietly, and without effort. It will be found of advantage to instruct him pleasantly as to the mode of procedure about to be employed; which procedure should be as gentle as possible; and the objects to be accomplished should be explained, in order to acquire his confidence; while, if sufficiently intelligent, it will be of service to place in his grasp a hand mirror, that he may watch for himself the manipulation of the operator, and see its results. This interests him, occupies his mind, and enables him to perceive that there is no danger of his suffering injury, and will be found an extremely useful method of allaying nervousness, and its effects on the irritability of the fauces.

The next thing to be done is *to introduce the laryngeal mirror.* As the reflecting surface of the mirror would become sullied by the halitus of the breath, from condensation of moisture upon its cool surface, it should be warmed or otherwise prepared before introduction. It may be warmed by simply holding it in the mouth a few minutes before proceeding with the examination (Watson); or it may be plunged into warm water; or it may heated over the lamp used for illumination, or over a small spirit-lamp kept for that special purpose. By warming the reflecting surface, the mounting which comes in contact with the tissues will not be so apt to burn the patient. And here it is necessary to utter a word of caution to beginners in this art.

It is customary for the examiner to test the warmth of the mirror, which should be brought to about blood-heat, upon his own hand, lip, or cheeks, before introducing it within the mouth of the patient. Notwithstanding this, there is great risk of allowing the mirror to become too hot, and thus burning the uvula of the patient when cauterization is unnecessary. The writer is indebted to Dr. Elsberg, of New York, for an excellent rule by which to judge when the mirror has received a proper degree of warmth. If a cold mirror is placed over a flame, moisture appears on its surface directly, and is gradually evaporated from its circumference towards the centre. As soon as the mirror clears, it is ready for use, having acquired a proper temperature. If the mirror is not well made, the heat will, after a while, affect the coating and destroy its reflecting power; and this is particularly the case with quick-silvered mirrors, which are thus soon rendered unfit for use.

Hot water, too, will gradually insinuate itself beneath the glass, and with a similar effect. A great deal of care is therefore required to learn the proper amount of heat necessary to retain the mirror undimmed during the examination. The rule given above, to watch for the disappearance of condensation, will be found highly satisfactory in practice. Further, the process of heating the mirror sometimes alarms timid patients, creating a nervousness which makes them dread the introduction, and strongly object to it. In these cases some other method of preparing the mirror is highly desirable. Dr. Buzzard, in a letter published in the *London Lancet* (American reprint for August, 1864), writes: "The dimming of the mirror arises, I suppose, from the deposit upon it of very minute globules of water, which, from their more or less spheroidal shape, scatter the rays in various directions, in place of allowing a right reflection. It occurred to me that a smooth layer of transparent liquid applied to the glass would at once absorb the watery vapor falling upon it, and thus prevent the dispersion of rays from this cause. I was not disappointed upon trying the experiment. Many liquids will answer the purpose, but the best which I have met with is glycerine diluted with an equal part of water. A drop or two of this should be allowed to fall upon the mirror (not heated), and to spread evenly

over its surface, just as the collodion is applied by the photographer. The reflecting power of the mirror is not manifestly interfered with by the presence of the thin and translucent layer; there is no dimming of its surface by the breath, and the application does not require to be repeated during even a long sitting. If care be taken that the coating is very thin, the amount of refraction produced by it is so exceedingly small as to be inappreciable in practice."

Czermak, in 1859, in putting into practice the suggestion of Neudorfer, to examine the inferior surface of the vocal cords, etc., by inserting a mirror through the opening formed by tracheotomy, found that his delicate mirror required to be frequently taken out to be reheated; and he applied successfully a solution of gum-arabic in water, and subsequently a solution of sugar and water, as mentioned in his monograph on the laryngoscope. The writer has frequently employed glycerine, especially when examining by sunlight. His plan is to spread with a camel's-hair pencil a thin film of pure glycerine over a well wiped mirror, and then to dip the mirror thus coated into cold water, shaking off the superabundant liquid, and repeating the process until a clear surface is produced, when the mirror will remain untarnishable by the breath for nearly half an hour. Every time the mirror is withdrawn from the mouth this immersion into cold water is repeated, in order to cleanse it from any mucous or any other secretion which may have adhered to its surface. It is rarely during an examination that the application of the glycerine has to be renewed, though the mirror be withdrawn and again introduced many times. The image appears to be as perfect as with a heated mirror.

Dr. Henry Wright has suggested keeping the mirror at a uniform temperature by means of the electric current; but this method requires a special and costly apparatus, which will prevent its coming into general use. The writer is personally unacquainted with any one in this country who, to his knowledge, has employed this method.

The mirror should not be retained too long in the mouth; it is better, even when the examination has been almost as thorough as had been desired, to re-insert the mirror many times, than to tire the patient by keeping it in position too long, or to excite nervousness and induce irritability; added to which, the saliva which accumulates at the floor of the mouth is sometimes of itself sufficient to excite reflex action. If considerable retching occurs during the course of an examination, it is advisable to forego further efforts at that interview; for although, by dint of perseverance on the part of the operator, seconded by force of will on the part of the patient, subsequent retching may be prevented, the mucous structures will have become so much congested in consequence of the spasmodic muscular action as perhaps to mislead the diagnosis. If considerable spasmodic or vibratile movement of the tongue or adjacent parts is observed in the introduction of the mirror, or during the examination, it is advisable to withdraw the instrument, and be contented for the time with an unsatisfactory result, rather than by attempting too much at first, to compromise subsequent success. When once retching occurs, a slighter disturbance than caused it at first will renew it, and render it troublesome to overcome; but if the examiner succeeds in producing no more irritation than the patient can overcome in his first effort, the confidence of the patient in his own powers of self-control will enable the parts to endure a much greater amount of manipulation than they could have withstood at first.

LOCAL ANÆSTHESIA.

By WILLIAM R. WHITEHEAD, M.D.,

(UNIVERSITY OF PARIS), FORMERLY PROFESSOR OF CLINICAL MEDICINE IN THE NEW YORK MEDICAL COLLEGE, ETC.

The attempt to substitute local for general anæsthesia in extensive surgical operations, offers the attraction of novelty, and the inviting advantage of avoiding the occasionally fatal accidents resulting from the inhalation of chloroform. The attention recently accorded to the efforts of Richardson, of London, to introduce to the favorable notice of the profession local anæsthesia by means of ether spray, will sanction a review of the relative merits of local anæsthetics.

From the most remote periods attempts have been made to produce local insensibility to the pain of surgical operations. Narcotics were topically employed by the ancients with discouraging results. During the last century compression was greatly extolled; but the constriction of a limb by tight cords to lessen the pain of an amputation was as inefficient as it was inconceivably barbarous. Arnott, in England, rendered temporarily popular a freezing mixture of salt and ice. I have seen this application made by Velpeau, for the avulsion of toe-nails; and the pain which it occasioned was intense. The cold produced by the rapid evaporation of ether induced Guérard, about 1854, to cause to be constructed by Mathieu,* an instrument provided with a small syringe, which should project ether in a continuously fine jet upon any part where it was desired to lessen or abolish sensibility. Hardy, of Dublin, in 1853, recommended the evaporation of chloroform as a local anæsthetic.

Follin and Leconte, several years ago (Bulletins de la Societé de Chirurgie), instituted a series of experiments to produce local anæsthesia.

By projecting a jet of ether on the skin, they produced insensibility of the part in less than a minute; and froze water in a small glass tube in less than two minutes. Great pain attended the application of the freezing mixture of salt and ice; and they further established that the complete anæsthetic effects which they obtained were in both cases due entirely to the congelation of the tissues. The success of these experiments caused ether sometimes to be used locally for minor operations, when the incisions were few, and involved only the integument. But the application of ether topically has unquestionably been greatly facilitated by the use of spray instruments; and if Richardson did not, a few years ago, meet with encouraging success in his endeavor to produce local anæsthesia by electricity, his adaptation of a nebulizer to the use of ether, though only an improvement on the method of Guérard, is productive of results that may retain this means of local anæsthesia among the recognised remedial agents which are exceptionally useful. In some of the recorded cases of success, as in the ovariotomy case of Spencer Wells, it was found necessary to administer chloroform to complete the operation; and furthermore, the experience of surgeons has not been confirmatory of the high encomiums lavished on ether spray in surgical operations of magnitude. I have recently used it in a plastic operation on a gentleman of this city, who had the choice of ether by inhalation or applied locally; chemically pure ether was used and applied by skilful hands. As the operation was performed by a few rapid incisions, and my object was only to materially diminish the sensibility, congelation of the tissues was not produced.

The impossibility of performing difficult dissections among frozen tissues must necessarily confine within

* Arch. Gén. de Méd., Avril, 1866, p. 499.

restricted limits the indications for this anæsthetic method; and it will be difficult to cause surgeons to abandon the positive benefits of chloroform for the doubtful advantages of local anæsthesia by ether spray. Since the effect is due entirely to the cold produced, I would prefer rhigolene to ether; but reserve it only for minor operations. There is a great variety of spray-producing instruments, and the perplexity in the choice of a suitable instrument can only result from a failure to make simplicity the requisite quality in the selection. Richardson's or Clark's will answer.

In almost any drug-store can be found a little instrument called the "scent distributor," for many years familiarly known to the public, and used for perfuming apartments. This little instrument is the simplest variety of nebulizer, and consists of two glass tubes arranged at right angles to each other. If the smaller tube should be passed through a cork stopper into a small bottle containing ether, and the other glass tube attached to a rubber-pipe connected with two hollow rubber balls at short distances from each other, one used for compressing air, and the other, which is nearest the bottle, as an air-reservoir, we shall have a representation of Bergson's apparatus modified by Clark.

PROF. OF ANATOMY, ETC.

Lecture II.

On Traumatic Stricture.

February 20, 1866.

Gentlemen—The patient before you is the carpenter who applied for relief three weeks ago (Jan. 30) with threatened retention of urine from impassable traumatic stricture of the urethra, and who was subjected to the operation of perineal urethrotomy on the first of the present month, *i. e.* twenty days ago. Before examining his present condition, I will read the note of his case:

Jan. 30, 1866.—G. J., twenty-eight, a healthy married man, fell astride of a beam whilst at work, about the middle of December last, with a great deal of force, from a distance of six feet. He suffered much pain at the time, and in two hours his scrotum and penis were black from effused blood. He passed bloody urine half an hour after the accident, in a thin stream and with much burning pain; and blood continued to ooze freely and spontaneously from the urethra for twelve hours afterwards. At the end of a week he thought himself well, and returned to work, but in a fortnight he had an attack of retention of urine, and his stream has ever since been steadily growing smaller. At present he has almost constant desire to relieve himself, and the urine, with violent straining, comes only in a succession of drops, and has several times stopped entirely. No instrument can be introduced into the bladder; an apparently impassable obstacle existing in the neighborhood of the triangular ligament. On several occasions, when suffering from retention, catheterization has been unsuccessfully attempted by different surgeons; relief following the use of hot water in bath and fomentations, at a varying interval.

In view of the great danger of retention and extravasation of urine, the operation of perineal urethrotomy was performed by Dr. Gouley, by my advice, on the day but one following.

After the patient was thoroughly etherized, I succeeded in introducing into the bladder a very fine filiform bougie of peculiar construction; and this was employed as a guide in the operation. The stricture, which was exceedingly dense, was freely divided upon a grooved probe longitudinally, in the median line, including a full half inch of the sound urethra in front of it, and the same behind it. A steel sound, No. 17, was then readily passed into the bladder, and shortly afterwards withdrawn, no catheter being left in the bladder. The hæmorrhage was trifling, no vessel requiring a ligature. The structure of the bulb of the urethra, which was involved in the incision, was distinctly observed to be dense, white, and bloodless; evidently obliterated by the inflammation which followed the original injury. The scrotum was supported by a sling bandage, and the patient placed in bed. He had no chill, and his pulse has never exceeded eighty in a minute. His urine was passed, with trifling smarting at first, through both wound and natural outlet. For the first forty-eight hours, in consequence of tumefaction of the edges of the wound, it found its way almost entirely through the urethra, as often occurs after the operation of lithotomy. Subsequently, on the establishment of suppuration in the wound, the greater part of the urine escaped through it. About the middle of the second week, the wound, which was covered by healthy granulations, began to contract, so that the urine flowed in larger proportion through the urethra. This proportion gradually augmented, so that by the middle of the third week none whatever escaped through the wound, and at present, on the twentieth day, as he shows you, there is nothing left of the wound but a narrow ridge of healthy granulations two lines broad and about an inch in length. The steel sound, No. 17, was not reintroduced until the fifth day after the operation; and it has been passed every second day since. You see now that it passes readily into the bladder.

You have before you, therefore, another successful example of the operation which I have recommended to you as the best and safest method of cure for traumatic stricture of serious character; and before completing what I have to say in reference to the details of the operation, I will ask your attention to one or two points of interest in the case as just narrated, which, I trust, may have already attracted your attention.

You will have noticed that after the patient had been etherized, and before he had been placed in position for the operation, I succeeded in introducing a fine bougie through the stricture into the bladder; a measure of great importance in facilitating the subsequent steps of the operation, and which, in my judgment, should always be attempted, just as it was done here, after the administration of the ether and before the use of the knife. It is a proceeding analogous to the final attempt to reduce a strangulated hernia by the taxis, after full relaxation has been brought about by the anæsthetic, and before the commencement of the operation. You may ask—Why was this not attempted before? and, when the instrument was got in, Why was not this success accepted as evidence that the case might be amenable to treatment by dilatation, and the cutting operation deferred? I will answer the latter question first: Because experience has taught us the

truth of Civiale's opinion, already quoted, that bad traumatic strictures are not curable by dilatation, and that their best remedy is incision from the perinæum. For these reasons this operation had been decided upon; and this being understood, earlier attempts to pass fine bougies might have provoked complete retention of urine, which is often the case, and thus have precipitated the necessity of performing the perineal operation under circumstances less favorable for its success.

I wish you to observe that the operation would have been performed in this case even if the attempt to introduce a fine bougie had failed; as Dr. Gouley and I had agreed that the safety of the patient and the requirements of sound surgery demanded it. The presence of the bougie as a guide through the dense stricture, simply rendered the operation less difficult and more certain in its accomplishment; perineal urethrotomy, without a guide, being justly recognised by all practical surgeons as an operation of very great difficulty, although in some cases it cannot be avoided. You should use every effort, therefore, to secure a guide to the bladder by employing the instruments best calculated to insure your success; and for this purpose I can recommend this delicate French bougie, which has been successful in both the cases recently subjected to operation. Besides its tapering point and extreme slenderness, its size being less than No. $\frac{1}{2}$ of the ordinary scale, it is saved from being too flexible and thread-like by the presence in its interior of a delicate fibre of whalebone, which gives it just the right amount of firmness. I think the use of these bougies will be more likely to save you from the unpleasant necessity of undertaking to find and divide an almost obliterated urethra from the perinæum than any other surgical resource at your command; and, of course, they are also useful for cases of stricture amenable to dilatation. I met with them as a novelty last summer in Paris; they are made by an instrument-maker named Benas, and Tiemann of this city has promised to import them.

I would ask your attention to another feature in the treatment of this case, viz. the size of the steel sound passed into the bladder through the divided stricture at the time of the operation, and which you have just seen introduced by Dr. Gouley. It is No. 17 of the English scale, which is the standard usually adopted in New York; and I have no doubt it seems to you a very large instrument. It is in fact very nearly half an inch in diameter, but not so large, as you perceive, as this cast of the urethra which I place beside it, and which represents the normal calibre of the canal. To be more accurate, the sound is three-eighths of an inch in diameter; whilst that of the urethra, as I have recently demonstrated to you, exceeds this measurement, reaching at several points half an inch, or even more. Moreover, it passes through the orifice of the urethra without pain or stretching; and this, as you know, is the narrowest point in the canal. I emphasize this point of practice because I believe that the diameter and capacity of dilatation of the urethral canal are generally underrated; and experience has taught me that the employment of steel sounds of the largest diameter which the urethra will admit, without painful distension of its healthy portions, affords the best chance of curing strictures without danger of relapse. This is especially true in reference to ordinary strictures following gonorrhœa, for which the proper treatment is dilatation; and here I am confident that more thorough dilatation, with sounds of larger size than those generally employed, would render relapse and recontraction of less frequent occurrence. The urethral orifice must be your gauge in the majority of cases; and this usually ranges from No. 12 to No. 16. In the patient before you, No. 17 was readily admitted; and I meet with urethras, not unfrequently, which will receive No. 18. Sometimes the orifice is normally smaller; and here, when necessity requires it, you have high authority for enlarging it by incisions. Guthrie, Civiale, and Thomson, advise this course. Remember that you should not attempt to *stretch* the urethral orifice; it is not only the narrowest point in the canal, but the most undilatable.

And now let me complete the description of the operation. Your patient should be placed upon a stout table of moderate size, in the position for lithotomy, with his perinæum previously shaved, and exposed to a good light. The height of the table should be not less than thirty-two inches, so that you can sit conveniently between the patient's legs. Ether should have been thoroughly administered, and its management committed to a trustworthy assistant. By means of an enema of tepid water the large bowel should have been completely evacuated. I assume that the introduction of a bougie, as a guide, has already been accomplished; by the aid of injection of warm sweet oil into the urethra, and employing the delicate instruments I have already described, with tact and perseverance you will rarely fail in this important procedure. A curved staff, with its groove extending flush to its extremity, is then to be carried down to the stricture and held in contact with it by an asssitant, who also holds up the serotum; the fine bougie occupies the groove of the staff. You proceed in the next place, with an ordinary scalpel, to make an incision as accurately as possible in the median line of the perinæum, commencing above over the extremity of the grooved staff, and terminating below about half an inch from the margin of the anus. This is to be carried through the subcutaneous connective tissue, the muscular fascia, the accelerator urinæ muscle, and the urethral walls, at the upper extremity of the incision, into the groove of the staff —taking especial care to keep accurately in the median line, and not to cut the bougie which occupies the groove of the staff, and which now comes in sight. You now require a silver probe of ordinary size, grooved on one side for one half its length, and tapering throughout its remaining half to a very delicate extremity, which terminates in a minute bulb. Withdrawing the grooved staff a little, you manipulate with the bougie, drawing its distal end out through the wound, and bringing into view as clearly as possible the orifice of the stricture in which it is lodged. By gently pushing the bougie to and fro through the stricture you can hardly fail to introduce the bulbous point of the silver probe alongside of it; and then pushing it onwards into the bladder, you engage its grooved portion in the stricture, and turning the groove towards the surface of the perinæum, by the use of a small curved sharp-pointed bistoury inserted along the groove, you divide the stricture carefully and thoroughly, and extend your incision fully half an inch into the uncontracted urethra beyond. An ordinary large director, or a female catheter passed through the divided stricture into the bladder, will now usually demonstrate, by the flow of urine, the completion of the operation; and, the urethra having been already sufficiently divided in front of the stricture, you should be able to introduce as large a steel sound as its orifice will admit through the urethra, and guide it past the wound into the bladder. If you encounter any obstruction whatever in the neighborhood of the recently divided stricture, you should seek out its cause, and at once remove it, if necessary, by further incision. It is well to remove the sound and reintroduce it several times, so as to become familiar with any peculiarities attending its introduc-

tion, and this will obviate any future difficulty in passing it. In regard to hæmorrhage, in the majority of cases there is no vessel requiring a ligature. If there should be troublesome oozing from the bulb, apply thoroughly to the bleeding surfaces Squibb's Solution of Persulphate of Iron, undiluted; I have often employed it, and find it both safe and sure. It only remains now to support the scrotum by a sling bandage, withdraw the sound, and convey the patient to his bed, which should be prepared with a folded sheet and india-rubber cloth beneath the buttocks.

The after-treatment consists in careful watching, simple feeding, and the introduction of the sound at appropriate intervals, as already indicated. Hæmorrhage, which sometimes occurs, is to be met (in case no bleeding vessel can be found and tied) by persulphate of iron, cold, and pressure—so applied as not to impede the flow of urine.

The dangers of this operation depend upon the conditions which necessitate its performance, rather than upon the proceeding itself. If, as is always to be desired, its necessity has been foreseen, and time secured for examination of internal organs, and ample preparation, the danger is trivial; but if, on the contrary, as often happens in Hospital practice, the patient falls into the surgeon's hands with prolonged retention or extravasation of urine, from recklessness and neglect, the result of the operation is likely to be much less favorable. And if, in addition to these serious complications, the stricture should prove to be impassable, and the operation is necessarily undertaken without any guide to the bladder, it becomes one of the most difficult and uncertain proceedings of surgery. The alternative of puncture of the bladder from the rectum, or above the pubes, may in rare cases be adopted from necessity; but these measures afford only temporary respite, inasmuch as they leave the stricture, the cause of all the trouble, unrelieved.

The operation I have thus described to you is equally applicable to cases of threatened or existing retention, or extravasation of urine from stricture following gonorrhœa, as to those of traumatic origin; and it presents this great advantage over all other surgical resources employed in this emergency, that it not only relieves the retention and averts its immediate consequences, but offers at the same time the best chance of cure for the stricture itself.

This operation is called by various names; in France it is best known by the old-fashioned and somewhat trifling name of *boutonnière*, or button-hole—from the shape of the perineal wound; English authors denominate it the *perineal section*. As this title has been monopolized of late by Syme's operation, Mr. Thomson, in his work on stricture—which I recommend to you as the best monograph on this subject in our language—proposes to designate this latter proceeding as "*external incision.*" I think the best name for it—one that is neither obscure nor incorrect—is that employed by Civiale: "perineal urethrotomy—with a guide, or without a guide." The former includes Syme's operation as one of its varieties; and the latter is identical with the old English *perineal section* and the French *boutonnière*.

And here I ought to explain to you just what is meant by "Syme's operation." Heretofore it has been accepted as an established canon of surgery *that division of the urethra from the perinæum is only justifiable in cases of stricture impassable by instruments.* Mr. Syme, Prof. of Surgery in the Edinburgh University, and whom I regard as one of the greatest living operators, in the year 1844 disputed this canon, asserting that in *intractable and "resilient" strictures which resist treatment by dilatation, even though still passable by instruments, section by the knife, from without, offers the most speedy, safe, and certain cure.* And he asserted also, pretty roundly, that there was (to him) no such thing as an impassable stricture; thereby bringing all cases of urethral obstruction, not curable by dilatation, within the scope of his proposed new operation. He has published a large number of successful cases to substantiate this new doctrine; but unhappily so much controversy and personal feeling have attended its promulgation, that its real scientific value has been obscured, and its general acceptance by surgeons has been retarded by this complication, which in matters of pure science is always to be deprecated.

You have already inferred that I accept Mr. Syme's views as correct; and I may add that I believe, with him, that really impassable strictures are rare. But in regard to his mode of operating I feel more hesitation in recommending you to adopt it. He introduces this slender grooved staff, No. 1 of the catheter scale, with a shoulder three inches from its extremity, and incises the stricture upon its groove. This instrument was made in Edinburgh; observe its slender point, and its large, defective curve—so different from that of the fixed portion of the urethra which I have demonstrated to you. After what I have told you of the dangers attending the use of slender steel instruments in the urethra, and of this shallow curve, which renders it almost impossible to keep its point in contact with the roof of the canal, you can understand how easily by its use a false passage might be made—as in the specimen I showed you yesterday from the dissecting-room, and you can see why I advise you to employ a bougie, in preference, as a guide. The operation I have just described to you may not be quite so brilliant or easy in its performance; but I am confident you will find it safer and more generally applicable.

There is another mode of treating obstinate strictures which has been much employed of late in England, and which promises to rival the operation of Mr. Syme, and that is the sudden dilatation, or, to speak more correctly, the laceration or tearing off the stricture by means of the instrument invented by Mr. Barnard Holt of the Westminster Hospital, of London. It consists of two metallic strips, with a central hollow stilet, all united at the beak, and forming a delicate curved sound about the size of a No. 4 catheter. After its introduction through the stricture into the bladder, as demonstrated by the escape of a few drops of urine through the stilet, this hollow tube, slightly curved at its extremity, is fitted upon the stilet and suddenly driven home, producing a longitudinal laceration of the stricture. The instrument is then withdrawn and a No. 12 catheter readily passed into the bladder. Mr. Holt kindly showed me the operation on two patients during my visit to London last summer, and the result was highly satisfactory. He asserts, from an experience of some 250 cases, that it is safe and effectual; recontraction occurring much less frequently than after dilatation, as usually practised. The idea of thus lacerating the urethra is not a pleasant one; but from what I have seen of the practice, I should judge that it is worthy of trial; and that it is especially applicable to cases occurring in hospitals, where the process of dilatation is so often tedious and unsatisfactory in its results. For the cure of traumatic stricture, however, I am not prepared to recommend this process, although Mr. Holt reports a case in which he employed it successfully. The cicatricial tissue outside of the urethral mucous membrane in a traumatic stricture would be less likely to recontract after free division by the knife, it seems to me, than after laceration, even though thoroughly effected.

I trust, gentlemen, that I have succeeded in impressing you with the idea that stricture of the urethra,

caused by injury of the perinæum, is a very serious surgical disease; more dangerous to life than stricture occurring in the ordinary way, inasmuch as it brings about so much more rapidly the very grave consequences which inevitably follow unrelieved obstruction to the free escape of the urine; and that these consequences are only to be averted by prompt and intelligent surgical treatment. Do not understand me as asserting that the operation I have described to you is necessary in all cases of this kind; or that the use of bougies and sounds for the purpose of dilatation is not occasionally successful. But I should mislead you if I did not state to you emphatically that these latter are occasional or exceptional cases; and that it will become your duty, in the great majority of traumatic strictures that you may encounter, to employ the more thorough surgical measures you have seen successfully applied in the cases we have studied together.

I cannot better close these remarks than by detailing to you the particulars of a very intelligently and honestly recorded hospital case which occurred fifteen years ago, and which exhibits very graphically the progress and fatal result, with the appearances seen on dissection, of a neglected traumatic stricture.

—— ——, ætat. thirty, admitted with retention of urine from stricture of the urethra, resulting from a fall astride a beam six months previously. On attempting to pass water some little time after the receipt of the injury, "he found that a considerable amount of blood had already escaped from his urethra, and his urine came with pain and smarting, and was highly colored by blood. By the next morning swelling and ecchymosis of the perinæum and scrotum had taken place, and he was unable to pass his water at all," and a catheter was introduced. The oozing of blood from the urethra continued for several days, and was afterwards mingled with pus. Subsequently pain and impediment were recognised in urinating, but no further retention occurred, although the stream has been steadily growing smaller until the time of admission, when "it comes from him in drops, and is only passed by a violent effort." There is noted also "a slight thickening of the tissues along the course of the urethra in the perinæum, not tender on pressure." No instrument could be got into his bladder; a chill followed each effort, and finally fever, with a brown tongue, diarrhœa, thirst, and nausea. Two weeks later, no relief having been afforded, "he is prostrate, failing very rapidly, pulse very feeble;" the urine occasionally dribbling from him involuntarily. Still later, "hiccough for four or five hours without intermission; urine turbid and tinged with blood, and passes altogether involuntarily." On the twenty-second day after admission he died, no means having been employed to relieve his bladder.

On *post-mortem* examination, the kidneys were found enlarged nearly one-third beyond the normal size, soft, flabby, and intensely congested, mottled with darker patches and spots, and with numerous small abscesses in their cortical substance near the periphery, and in fact "throughout the whole substance of the organs." Ureters vascular; bladder very much contracted, "containing ℥ ij." of reddish, opaque, cloudy urine;" its walls half an inch in thickness; drops of sanious pus oozing from numerous points of the surface of its mucous membrane, which, by the aid of the probe, were found to lead into small abscesses seated in the walls of the organ. Numerous abscesses also existed in the substance of the prostate gland. Immediately behind the bulb of the urethra—*i. e.* in its membranous portion—was seated the stricture, "about four lines in length, and would admit a small instrument." Just behind it, in the floor of the urethra, was a circular opening of three lines in diameter, with rounded puckered edges, leading into a cavity situated in the perinæum, and capable of containing a good-sized hickory-nut.

By referring to the works of Rayer, Brodie, or Wilks (Pathological Anatomy), you will be satisfied that the lesions observed in this case were due directly to the stricture, which, by obstructing the escape of the urine, gave rise to an inflammation involving the whole track of the urinary mucous membrane, and extending to its subjacent tissues; and which, finally invading the secreting structure of the kidneys, arrested the function of these vital organs, and thus caused death. There was no pyæmia in this case. The man was in good health when the injury befel him which caused the fatal stricture; and the period intervening between the injury and his death was only six months. This is not a unique case. I have records of several similar ones. I lap it before you as an example of a result which may be anticipated in any severe case of traumatic stricture, or in fact in any case of serious organic stricture; a result which is to be averted by the employment of prompt and effectual measures to restore a free passage for the urinary secretion.

Reports of Hospitals.

BELLEVUE HOSPITAL.

PROF. F. H. HAMILTON'S CLINICS.

I. Epithelioma and Caries of Calcaneum. II. Cleft Palate.

Saturday, 13th January, 1866.

I. *Epithelioma and Caries of Calcaneum: Amputation.*—Ann H——, æt. 60 (probably), Irish domestic, admitted January 6. The affection began in childhood as a small tubercle upon the integument of the right heel (an unusual site for epithelioma), which persisted and finally ulcerated. The ulcer has continued many years, showing no inclination to close, but steadily progressing, until you see it now about two inches and one-half in diameter, and nearly circular. Its surface is pale, red, and irregularly excavated; its edges are irregular, elevated, and everted. It is probable that the os calcis is involved. The patient is otherwise apparently well.

Epithelioma is commonly accounted a local affection. So it is in a certain sense; but, as in the great majority of so-called local affections which resist treatment, its persistency has a constitutional cause. The simple fact that such a lesion does not heal spontaneously, is evidence, in most cases, of some fault of the system. A slight scratch may, in a feeble old man, become an ulcer from lack of constitutional reparative power. An irritation of the conjunctiva, which in your case or mine would occasion but a few hours' annoyance, becomes in the scrofulous woman, or the man of intemperate habits, a tedious chronic ophthalmia. I believe hospital gangrene to be an illustration of the same thing. It is a local poison, engrafted upon a constitutional fault. Clearly all attempts at treating affections of this kind as purely local will be abortive. It is from ignoring this important principle that specialists often fail. The oculist, aurist, obstetrician, must know the whole body, as well as that part of it to which he is specially devoted. In this woman, then, we must assume some cachexia; but as the general system shows no signs of it, I have hope that the disease may be so far a local one as not to return if the affected parts be thoroughly re-

moved. Were it scirrhus, I should be quite certain of its reproduction.

For the removal of such lesions of tissue as epithelioma we may employ either caustics or the knife. The former will extirpate the morbid tissue as effectually as the latter, but after their use the cicatrization will be slow; and, bearing ever in mind the constitutional fault, you will see that this tardy cicatrization increases greatly the chances of a return of the disease during the healing process. And if this be escaped, the feebly vitalized cicatricial tissue will still be prone to take on the morbid action; and as it contracts, becomes tense, and perhaps cracks open, this result will be almost insured. If, on the other hand, the affected part be cleanly cut out, sound skin may be transplanted and cover the wound, by which it will be closed in speedily, and all these sources of danger will be avoided. It is to this transplantation alone that I attribute the greater success of excision.

In the present case a plastic operation would be difficult; and, moreover, the calcaneum is probably carious, which would render it valueless. Resection of this bone would be open to all the objections urged against caustics. A modification of Syme's operation might possibly be made, taking the flap from the dorsum of the foot; but I doubt if the tissues, from which the flap must be made, are sufficiently healthy. I have therefore, upon consultation, decided to amputate above the malleoli; and I think the woman's general condition gives her a fair prospect of recovery. I shall not make the double flap operation which you have just seen so beautifully performed upon the thigh by Dr. Wood,—first, because that is not well adapted to the lower third of the leg; and secondly, because the circular will expose less surface.

You will recall the double amputation of the arms made by me a few weeks since. The subject was a temperate young man, in full vigor. Both arms had been caught and crushed between two rollers, and both had apparently suffered the same amount of injury. Upon one I performed the circular amputation, and upon the other the flap, the humerus being sawn at the same point in each. The patient died of pyæmia, though his progress for two weeks was so remarkably good that I still think he might have recovered, if, instead of the infected hospital atmosphere, he could have breathed the pure air of a comfortable private house. We observed that the flap stump required twice as many ligatures as the circular, and that it suppurated at least twice as profusely. The extent of union was the same in both. In both humeri osteo-myelitis had taken place; but the microscope confirmed what was apparent to the naked eye, that the disorganization of the medulla was both more extensive and more complete in the former than in the latter. That case would, then, incline us to the circular operation. One case, however, cannot settle the question; though a series of twenty-five or thirty such might go far towards it. But we can never come to any satisfactory decision from the statistics of the two operations as performed upon different persons, where no degree of accuracy in observation can assure us that all the conditions were precisely similar. Until, then, we have data more unquestionable than at present, surgeons will remain at liberty to elect either method. I must confess, however, that I am fully convinced we ought to choose the circular for patients who are old or much enfeebled from any cause. I see present a gentleman who, during his long charge of Armory Square Hospital at Washington, has probably had more experience in amputation than any other surgeon in the war. Will Dr. Bliss give us his views as to which operation has shown the greater number of recoveries?

Dr. Bliss.—I would say most decidedly, Doctor, the circular. This I have observed both in my own and in those field amputations which had endured transportation to the hospital. Entering the war with a strong prejudice in favor of the flap operation, it is only the most unequivocal experience that has led me to give a general preference to the circular.

Dr. Hamilton.—I trust the Medical Bureau may soon give the world the benefit of your experience upon this subject.

Operation. — Patient etherized. — Skin-incision one inch and a half above the malleoli, with a vertical incision along the back; muscles and bones cut three inches higher; three ligatures; flaps left open a short time, then brought together laterally, and confined by sutures. (This patient made a slow, but complete recovery.)

II. *Cleft Palate.*—I present you here a case which would be deemed a fit subject for staphyloraphy. The fissure in the palate is rather narrow, and in the act of swallowing it is nearly closed. This operation was introduced by Roux in 1811, I think, and has been growing in favor, especially within the last fourteen years. I have several times performed it, but with results inferior to those of Dr. Warren of Boston, and Dr. Mutter of Philadelphia, in whose hands, as representatives of American surgery, it has been the most successful. I have concluded that it demands great expertness in the surgeon; that even the most expert must often make several attempts before completing a satisfactory operation; and that when this is accomplished, little or no improvement in the articulation will generally be secured, though to effect this was the chief purpose of the operation.

Operative surgery proving here so inefficient, the field is opened to inventive skill; and a dentist of this city has, after much study, perfected and presented to the profession a most ingenious appliance. Let me introduce to you Dr. Kingsley, who will show you his artificial palate and explain its adjustment.

Dr. Kingsley.—My attention was drawn to this subject six or eight years ago, by the fact that staphyloraphy, where surgically most successful, even to the union of the bifurcated uvula, failed in nearly every instance to remedy or materially to palliate the defects of speech. These are great; for, next to the tongue, the palate is the most important organ of articulation. It is this delicate movable curtain which directs the voice, now through the mouth, and now through the nose. I conceived the reasons why its function is not restored by the operation to be, that the velum thus formed is commonly too short to close the nares, and is at any rate stiff and tense, while its controlling muscles have in most cases been cut away.

The desideratum was an artificial palate, which should be under the control of the palatal muscles, and could be worn without discomfort. Five years ago I had devised the apparatus which met these indications; but it was inconveniently complicated. This which I now show you, in a single piece of flexible rubber, could not be made more simple; it is as readily adjusted and as easily worn as a set of artificial teeth, and, I think, answers perfectly its purpose.

By the aid of this instrument the patient may *learn* to articulate every sound distinctly. No immediate improvement is to be anticipated; for habits formed from birth are to be broken up, and the process of learning to talk must be begun anew, at least with reference to certain vocal elements. This consideration warned me not to be too sanguine of success; but, except in one class of cases, time has proved the result all that could be desired. It is found, moreover, that those who

have once acquired a correct enunciation by the help of this instrument, can, even without it, articulate more clearly than before — dormant powers having been awakened in their training.

In cases complicated with hare-lip the result is less satisfactory; and observation has shown that the chief difficulty is manifested in those where a large open nostril has been left as the consequence of a surgical operation. Where the nostril is small, though a notch may remain in the lip, little trouble is experienced; the compressor nasi, whose office in articulation is not unimportant, being here able to cover the defect.

[Dr. K. proceeded to demonstrate the instrument and exemplify its action, relating also several cases of its application. As he stated that he was about publishing a descriptive paper, these illustrations are here omitted. He described also a contrivance successfully applied to facilitate articulation after staphyloraphy.

Two young men having cleft palate were introduced. One was using the artificial palate of Dr. Kingsley; and the improvement of his voice, tested by introducing and then removing the palate, was very marked. "It is true, however," remarked Dr. Hamilton, "that it is not all, in this respect, which might be desired, and perhaps not all which may hereafter be attained."—*Reporter.*]

Progress of Medical Science.

What Local Anæsthesia may Accomplish.—Dr. Richardson, at the request of the president and members of the Harveian Society of London, made some interesting and suggestive remarks upon local anæsthesia. He gave it as his opinion that the effect of his ether apparatus was probably entirely due to the cold generated by the rapid evaporation of the ether. The action of cold in thus producing insensibility was due, he thought, to the fact that the force of sensation in different parts was brought down by the blood. When we touched a part more motion was produced, and consequently more sensation. When a part was frozen the blood could not supply sufficient heat to keep up the sensation of the part. Nerve force was brought down by every contraction of the heart. As a verification of this view he mentioned that local anæsthesia could be much more rapidly obtained if, whilst cold was applied, the vessels leading to the part were compressed. Thus when the toe-nail is removed, pressure should be made on the anterior tibial artery, and thus we are enabled more rapidly to produce complete absence from pain. With regard to the apparatus required for operation, he generally carried about with him a 3-division bottle having three jets near each other, and all fitting together in a leathern case. By means of this apparatus the operation of Cæsarian section had been painlessly performed, and a tumor in the neck, requiring an incision of seven inches, had been removed by Mr. Adams. When a part is to be frozen it should be previously carefully and perfectly dried; otherwise a film of ice formed, and obstructed anæsthesia. This was the reason of the difficulty in the operations of dentists. In some cases hoar-frost is deposited on the surface of the part; but anæsthesia may be obtained in such cases. If alcohol or chloroform were added to the ether, hoar-frost appeared. The test for the purity of ether consisted in finding whether it would boil when poured into the palm of the hand. This could be ascertained by holding the hand near the ear and listening. One caution he would give—the use of chloroform had introduced a certain carelessness into operations; the operator would sometimes talk when operations were made, which might cause, as he had witnessed, syncope of the patient. Now that anæsthesia was local, solemn silence should be maintained. At first it had been thought that the process was only suitable for small operations: but ovariotomy had now been successfully performed by it four times; amputation of half the foot, too, had been performed; operations for strangulated hernia had also been performed with success three times; something, too, had been added in the last case, since the cold sometimes caused the hernia to become reducible. In Cæsarian section the advantages of the process were enormous. 1. There was no bleeding—a circumstance which used to render the operation extremely hazardous. 2. The cold made the uterus contract. Amputations of the thigh had not been tried. When there was any doubt, chloroform ought to be used; but in cases requiring amputation of the thigh, if cardiac disease was present, he would not hesitate to use it. A single jet did well for a carbuncle. In whitlow the application was most useful; sometimes it will cure the complaint. In the last stage, if the artery of the finger were compressed, and cold frequently used, the complaint could be cured in three days. There was sometimes a little pain felt in applying the spray to the hands and forehead. He had not yet seen sloughing follow on its application. In Bright's disease blistering of the skin was produced. With regard to its use in medical cases, whenever the pain was thoroughly local, freezing would relieve it. In cases of conjunctivitis it had proved of service. He had recently made use of a styptic ether for surgical operations, and had found it of great service; the ether was mixed with xyloidine or starch dissolved in nitric acid. In the case of a young gentleman with a hæmorrhagic diathesis, who had nearly bled to death from the extraction of a molar tooth, he first froze the part and then plugged it by the styptic, so that the bleeding was completely stopped. He believed that use might be made of this application in post-partum hæmorrhage. As to any danger from the use of ether spray in ovariotomy, this was groundless. So volatile was the ether that we cannot even swallow it if we would. He had often asked himself whether this plan might not prove an anæsthetic in labor pains. He believed it would be found to diminish the pains of labor if the spray were allowed to play on the sacrum during the pains. As to tooth-drawing, there was no difficulty in extracting the upper teeth without pain; but in the back and lower teeth there was difficulty, because of the saliva becoming frozen. In one case he had applied cold to the cheek, and had thus caused painless extraction of the teeth.

Dr. Tyler Smith is of the opinion that the external application of ether spray would be of more service in controlling post-partum hæmorrhage than when applied to the uterus itself, especially as there was otherwise great danger of admitting air in the uterine sinuses.—*Dublin Medical Press and Circular.*

Treatment of Itch.—The Prussian military authorities cure itch by smearing the parts with a mixture of two parts of liquid storax with one part of sweet oil. The cure is said to be complete in twenty-four hours.

The Injurious Results of an early Extraction of the Permanent Teeth—Conservative Dentistry.—Dr. A. C. Hawes, of this city, has published in the May number of the *Dental Cosmos* an article entitled "The Injurious Results of an early Extraction of the Permanent Teeth." The writer's object is to inculcate the impropriety of removing, unless in exceedingly rare instances, any of the teeth of the second set for irregularity. He remarks that "by the extraction of a bicuspid or a six-year molar, the whole character and beauty of the

mouth, in all its active and playful motions, may be permanently destroyed; and in the place of the broad, full, and well rounded arch, thickly studded with precious gems, there will remain but a narrow and contracted deformity, almost wedge-shaped, which the most intelligent skill of the dental profession can never restore. What excuse, let me ask, or what recompense can atone to the parent or to the child for the infliction of a life-long injury such as this?"

The second part of the subject, the manner of remedying crowded conditions of the teeth, is, like the first, treated at considerable length. Dr. H., relative to this particular, states that "most of the irregularities of this kind, with the growth of the jaw would gradually correct themselves; and in the rare exceptions where this might not occur, would it not be better to bring *dental skill* to the support of nature, by aiding her to force the teeth into their proper places, thus preserving what is so valuable and necessary for a lifetime, than to inflict a far worse evil by resorting to extraction? That surgeon would hardly be accounted judicious who, in treating an irregularity of any other organ, as a case of strabismus for instance, should proceed to remove an eye because its angle of vision was more convergent or divergent than the other, instead of adjusting the visual axis of the two alike. It is easy enough to destroy nature; but it is the province of intelligence and skill to preserve it."

Results are reported, in conclusion, with plates to illustrate, which convince of the practicability, by mechanical means, under proper management, of correcting in almost all cases defects in the relation of the permanent teeth without resort to extraction.

The Screw Clamp in Hæmorrhoids.—Mr. Henry Smith, F.R.C.S. (*Lancet*), reports thirty-five successful cases of hæmorrhoids treated by his screw clamp, and considers that the good effects of the employment of the instrument in such cases, in connexion with an equal number already published in his Lettsomian lectures, fully warrants him in urging its claims to universal employment. He maintains "that the operation by the clamp is a safer, a less painful, and a quicker method than that by the ligature, for in no case has death occurred, nor in any one instance has anything taken place which caused the least anxiety. Most of the patients have been walking about in a week or less, and in the larger number of cases the after-suffering has been slight."

Deaths by Battle and by Disease.—According to statistical tables, mainly derived from the recent report of the Provost-Marshal-General, it appears that during the progress of the last war we lost, in officers and men, killed and died of wounds, 96,099; and by disease, 184,321; or, altogether, 280,410, out of a total given in these tables at 2,154,311. In the Crimea, of nearly 94,000 English soldiers, 4,419 died by battle, and 16,298 died of disease at the seat of war, while nearly 13,000 more were sent home sick. Thus the English losses by disease were nearly four times those by battle. The French, whose sanitary regulations were much praised, were even worse. They lost 7,500 men by battle, 50,000 by disease—nearly seven times the number of casualties, instead of less than twice, as with us; and 65,000 more were sent home to be discharged as invalids, a considerable proportion of whom no doubt died of their diseases.

In the Mexican war, according to government returns, only 1,548 men died in battle or of wounds, but 12,348 died of disease, and 12,252 were sent home sick. This, owing to inefficient sanitary provisions, was worse even than the Crimean returns.

Among the white troops, it is stated that the proportion of deaths in action and from wounds to the deaths from disease was about as one to two; among the colored troops as one to eight. About 180,000 colored men were enlisted in the army during the war, of whom, accordingly, nearly one out of every seven died of disease. The general proportion among white troops is one to fifteen.

It appears, also, that both from battle and from disease New England sustained the heaviest losses. The fatality of maladies among the troops from this region is ascribed to the fact that an undue proportion of them were used in the unhealthy Atlantic and Gulf States of the South. The men of the West, who rate next, served in the fever-breeding valleys of the Mississippi and its southern tributaries, and this aided no doubt in swelling their mortality list. The troops from the border States suffered mainly from the same cause. All their ratios are higher than the general ratio of the loyal States, which is but 59.22.

These statements, we are informed, are intended to comprise only officers and men who died in the service, and not the tens of thousands who were discharged for disability contracted in the service, from the effect of which they subsequently died in private life.

Vessels and Nerves of Ligaments and Fibro-Cartilages.—M. Sappey, in a memoir recently presented to the French Academy, maintains that the white fibrous tissues and fibro-cartilages, far from being non-vascular, as is generally supposed, contain not only blood-vessels but nerve filaments. He instances the inter-articular cartilages of the knee as those which are most abundantly supplied. After the ligaments and peri-articular cartilages, the tendons and aponeuroses are the next most favored tissues in this category; and last of all come the interarticular fibro-cartilages. He says (*Lancet*) that the vessels run at first nearly parallel with the connective tissue fibres, but soon they divide and subdivide and anastomose, so as to form the most exquisite reticulations and terminate in elegant festoons. The veins follow the course of the arteries. In the fibro-cartilages of the joints the vessels pass from the periphery towards the centre; but they penetrate only to a depth of three or four millimetres. The peri-articular fibro-cartilages, or brusæ, are still more vascular. Both these sets of tissues receive numerous nerves which lie with the vessels, and at others pursue an independent course. The ligaments are also well supplied with vessels and nerves, especially the latter, which are more numerous than those of the skin (!). In the tendons the supply of nerves and vessels is less marked.

Citrate of Soda in Diabetes.—M. Guyot-Danecy, basing his practice upon the theory that diabetes arises from the imperfect combustion of the glucose of the blood, proposes to employ citrate of soda in order to supply the alkaline carbonate which is necessary to the progressive change of the glucose. He substitutes the citrate for the carbonate, because, he says, it does not affect the function of digestion. He administers the salt in doses of from four to eight grammes. His analyses, he alleges, demonstrate that sugar disappears from the urine after the administration of the citrate. Citrate of soda may be mixed with food instead of salt, and with it the use of ordinary bread and starchy matters ceases to be objectionable.—*Lancet.*

Ophthalmia is said to be raging among the women and children of the troops in Meerut.

THE WILLARD ASYLUM AND THE CHRONIC INSANE.

Two years ago an investigation was ordered by the New York Legislature into the condition of the insane poor in the various county houses scattered throughout the State. Under this law Dr. S. D. WILLARD, as Secretary of the State Medical Society, conducted the inquiry. A vast amount of cruelty and misery was brought to light by the broad, minute, and searching examination thus instituted. Dr. WILLARD's unvarnished and appalling statements startled the Legislators of New York, and the result was a law establishing an asylum for paupers deemed incurably insane. Commissioners were soon after appointed to choose a site and to erect the buildings. They have located the institution at Ovid, and are, we believe, making arrangements to build.

This promptness of legislative action, under the evidence of a great want, commands our warm approval. It is pleasant to find men in power who are quick to feel and quick to act. But neither in private nor in public action is it always safe to follow the first impulses of benevolent emotion. Our Legislators, looking at the vast amount of suffering among the insane paupers of the State, subjected to harsh treatment from the unfeeling officials of the almshouse, thought that they could not do a better thing than to create a grand retreat for their sole use and comfort. In this we think they made a serious mistake. We shall state briefly some of the grounds on which our opinion rests.

In the first place, we cannot think it right to assume that insanity is incurable. Many cases indeed there are, in which the disorder is of life-long duration. The probability of restoration to mental health is, we admit, often exceedingly small; yet reason has sometimes returned after the lapse of many years, and in instances which had long been regarded as hopeless. We know not in how many thousand cases the continuance of disease is due to the lack of skill and care, or to the aggravating effects of positive unkindness. We do know that many disordered minds are more or less conscious of the nature of their malady, and are not without a hope that they will recover? Can we doubt that the existence of such an expectation adds much to the probability of its being realized? Can we afford to dispense with a remedial agent so efficient and valuable? Can we be justified in making any arrangement for the insane, which has a tendency to extinguish in their breasts this last solace?

We see not how any one can doubt that such would be the natural and inevitable tendency of an asylum for incurables. In the regular hospital intended for the cure as well as the relief of insanity, there is always much to encourage the afflicted inmate. Patients are constantly going as well as coming. They are seen to enter in a state of disorder and distress; they are afterwards seen departing happy, and in their right mind. In all this there is a silent moral influence of incalculable value—and this influence would be entirely wanting in a pauper hospital for supposed incurables.

Another serious objection to such an establishment is found in the fact that it is created and opened for paupers only. The very word "pauper" is odious, and all its associations are dreary and repulsive. These poor people have for the most part become poor, not by any fault of theirs, but in consequence of the malady which has thrown them on our hands. Shall we add to the bitterness of their lot by ranking them with the most despised and degraded class in the community? If with some of the insane this would make no difference, there are not a few who are keenly sensitive to such considerations.

But we find a still stronger reason against the establishment of hospitals for insane paupers in their inherent and inevitable tendency to neglect and abuse. The Asylum, which contains patients of every class and condition of life, never ceases to be an object of interest and of care to the community outside. Should abuses creep in, should the managers and employés become selfish and cruel, the facts will come out. Among the friends of these patients who are in comfortable circumstances, there will always be found enough who are willing and able to make the requisite investigations, and to apply the needed corrections. The poorer patients may not be thought of, yet none the less will they share in the benefits resulting from this unofficial supervision.

But in an institution composed wholly of mad paupers, who will look after the friendless inmates, should they be subjected to harsh treatment? The danger that they will be abused is found in this very fact, that they are poor, friendless, and powerless. Do we not know from sad experience that this is the tendency of things in all such establishments? The evil results of such a system might not appear at once. It might be started under good auspices; its first officers might be humane and intelligent men, actuated by an honorable ambition

to achieve success and win approval, and they may resist for a time the dangerous proclivities of their dismal position. But if they do not fall, their successors will. The temptation to a selfish abuse of power will be too strong for weak human nature. We shall be agreeably disappointed if the great pauper mad-house erected to relieve the poor victims of almshouse cruelty, does not itself become in time an intolerable bedlam!

The danger of hard usage on the part of those who are to act as officials in the institution proposed is greatly enhanced by the fact that it is brought forward as an *economical* measure. An asylum like this, it is alleged, will not cost so much to begin with, and will cost less to maintain. Its advocates make much account of the labor which is to be got out of these poor patients. In this way the establishment is to be made, to a great extent, self-supporting. To realize this idea and fulfil these promises, how probable it is that the unfortunate and unfriended inmates will be pushed beyond their strength? Under the predominant purpose of attaining to a pecuniary result that shall be satisfactory, the health and comfort of the paupers are too likely to be regarded as inferior considerations.

If experience is worth anything, if there be any value in the observations and conclusions of those who have seen the most of insanity, both in its capacities and its wants, this idea of a financial advantage is utterly chimerical. This labor question is not new; it has been tried and tested. Attempts to render insane labor a source of pecuniary profit have been made in America under circumstances as favorable as any which are likely hereafter to occur. In no instance could they be called successful. If more has been accomplished in some of the English asylums, it may be ascribed to causes which do not and which cannot exist here: to a less exciting climate, for instance, and to a larger proportion of patients who are already skilled artisans, than can be found anywhere on this side the water.

In any considerable collection of the insane, there are always some patients to whom moderate occupation is useful, if not remedial. Every well planned and well conducted hospital will have a sufficiency of suitable employment for this class of persons, and their labor will do something towards a reduction of expenses. Much more than this, it is in our opinion idle to expect. We are told that there is to be a *saving of expense* in the keeping of these poor folks! Are they to be stinted in the matter of food, clothing, and fire? Is our great, wealthy, and generous State ready to go into so small a business as that of pinching her innocent, needy, and demented children in the quality and quantity of what they eat and drink? Surely to that question the answer which would come up from all her cities, villages, and fertile plains, would be an indignant No! More than any other class of persons, the insane require a nutritious and generous diet.

It might easily be shown that the first cost of buildings for a pauper hospital, and the salaries of its officers and attendants, would not vary much from what is required by institutions which are open to all classes of insane. But for these details we cannot spare the space

The only argument of any weight in favor of especial establishments for the chronic insane is, that they make a desirable separation between those whose malady is supposed to be curable and those whose cases are comparatively hopeless. In every institution for the relief of insanity, the means for effecting such a segregation ought certainly to, and does, exist. The extent to which it should be carried may safely be left to the judgment and care of those who have the immediate management. So far as the classification of cases and the rectifying of errors are concerned, the advantage would clearly be with one asylum rather than with two. We can see nothing that would be gained; we see a great deal that would be lost, by an arbitrary separation of the two classes, and especially by placing them a considerable distance from each other.

With these views of the general question—views held in common with almost all those medical men who have had any experience and responsibility in our American hospitals for the relief of insanity—it is impossible for us to look upon the project of the Willard Asylum as anything less than a great and unfortunate legislative blunder. It is to be regretted as an enterprise which has taken a wrong direction; it is a waste of strength greatly needed elsewhere.

The vast and populous State of New York unquestionably needs more ample provision for its insane. The central institution at Utica, huge as it is, comes very far short of meeting the demand. The recent establishment of the Hudson River Asylum is one good step taken. Similar accommodations must ere long be accorded to the western section of the State; and the time, we trust, is not far distant when, through a judicious distribution of the benefits, these benignant retreats for disordered minds will be sufficiently numerous to receive and to accommodate, without crowding and without exclusion, all who are so unfortunate as to need their aid.

THE STATE MEDICAL SOCIETY OF MICHIGAN.—A meeting of the medical profession of Michigan took place at Detroit June 5, for the purpose of reorganizing the State Medical Society. Dr. C. M. Stockwell, of Port Huron, Michigan, has been elected president. The next meeting will be on the first Wednesday in June, 1867, in Detroit. We notice with pleasure that the Society voted "to sustain by their support and patronage the Detroit Review of Medicine and Pharmacy."

ADULTERATION OF OPIUM.—Landerer states that opium is adulterated in Asia Minor (Turkey opium) with crushed raisins and salep. The former is detected by ascertaining the presence of grape sugar with Barreswil's or other cupro-potassic solution; the latter will be recognised by tincture of iodine showing the reaction of starch.—*The Detroit Review of Medicine and Pharmacy.*
